true and atypical facial neuralgia is difficult and alcohol injection is a very satisfactory way to differentiate between these conditions. Lastly, a successful alcohol injection with relief of pain accustoms the patient to the numb area in the face so that when operation is performed with permanent removal of the pain the patient will know just how his face will feel. I must disagree with Dr. Dandy that a radical operation is the primary treatment for these cases. Dr. Sachs has, I am sure, had the same experience that I have had. I have seen cases of atypical neuralgia so closely simulating the true major neuralgia that immediate operation seemed entirely justified. The sensory root was completely severed and the trigeminal sensory area rendered permanently anesthetic. But the pain continued and furthermore the patients complained bitterly about the anesthesia of the face. I have never seen a case in which, following a successful peripheral alcohol injection, failure to relieve pain was noted, that was subsequently relieved by sensory root section. It is as an aid in differential diagnosis and the avoidance of unnecessary sensory root resection that peripheral alcohol injections are most valuable. Dr. Hassin commented on the position from which the second division injection was made. The original Levy and Baudouin technique punctured the cheek farther forward. When I was practicing this technique on the cadaver, as is noted in a paper published in 1923, I found that if the injection was made from a point 5 cm in front of the external auditory canal and the needle was inserted too deeply, the optic nerve could be injured. The injection from the 3 cm mark in front of the external auditory canal does away with this danger. I believe that the second division may be reached just as easily from this point as from farther forward. None of these techniques for peripheral alcohol injection of the maxillary or mandibular branches should be attempted on a patient without careful experience on the cadaver.

OCULAR HYPERTENSION IN GLAUCOMA

ERRORS IN OPERATIVE TECHNIC LIKELY TO CAUSE
FAILURES IN OPERATIONS FOR ITS CONTROL

WEBB W. WEEKS, M.D.
NEW YORK

Since the operative procedures to be discussed for the reduction of increased intra-ocular tension have to do directly with the anterior segment of the eyeball, it seems advisable to consider only this portion of the eye.

It is assumed that the cases judged operable have been thoroughly worked up, with the elimination of all conditions likely to interfere with or subsequently nullify the possible success of an operation. Constitutional, metabolic, nutritional states, tissue change due to age, and focal infections all have to be determined and weighed as to their influence on tissue repair, hemorrhage or infection. As Colonel Elliot¹ puts it: "Eliminate all sources of endogenous sepsis, observe scrupulous sepsis." The latter point was strongly emphasized by Clifford Walker last year. He showed that even small particles of foreign matter in a trephine tip were the source of irritation, congestion and infection. The judgment skill and care in carrying out operative procedures should further be safeguarded by keeping the patient quiet, using hypnotics or even a general anesthetic. The Van Lint² lid block, a thoroughgoing local anesthetic and a retrobulbar anesthetic by way of the capsule of Tenon or by a chiasm ganglion block should be used.

Read before the Section on Ophthalmology at the Eighty-Sixth Annual Session of the American Medical Association, Jan. 23, 1933, May 14, 1936.

³ Personal communication to the author.

The type of operation to be done is based on the estimated change in tissues and any alteration in the position of the parts involved in an eye with hypertension, and carried out only after proper measures—local and systemic—have been thoroughly tried and have failed. The consensus is that medical measures are apt to be carried on too long, permanent damage occurring, or that the patient has waited too long before seeking advice and operation. Should the tension be too high to operate safely, an anterior or posterior sclerotomy may be necessary to reduce tension and deepen the anterior chamber.

Light, dextrous, deliberate, clean-cut operative methods with the least amount of trauma to the tissues always secure the best results. Rough handling or bruising of tissues, so that a congestive irritation is set up, delays healing and encourages infective processes.

Magitot² says "All operations, iridectomy, cyclodialysis, sclerecto-iridectomy, may have good or bad results. This does not depend upon the technic but upon the nature of the local condition, the vascular disorder. The glaucoma is a symptom, the hypertension a disease."

The classification of the types of glaucoma and the operative procedures most commonly used as suggested by Gradle³ will be followed.

The therapeutic iridectomy is aimed at the reestablishment of the normal pathways for the drainage of intra-ocular fluids. Its object is to make a limbic incision, to excise a portion of the iris, to free the filtration angle before anterior peripheral synechias have solidly formed, to open a free passage between anterior and posterior chambers and to revive the equilibrium of inflow and outflow of ocular fluids by way of the iris circulation and filtration angle.

The Incision—In the words of von Graefe⁴ (a) it should be as eccentric as possible in order to remove the iris as far as its ciliary attachment (this is essential to success), (b) the aqueous should be allowed to escape slowly.

The usual tendency in making a keratome incision especially if the anterior chamber is shallow, is to make the incision too far forward in the cornea in attempts to avoid the iris, or if all allowance is not made for the corneal curve or the position of the eye when the patient looks down the incision is made too obliquely, producing a corneal shelf posteriorly as shown in post-operative microscopic sections. In either event, the iris cannot be removed up to its root, a portion is left to adhere in the filtration angle.

If the incision is made with a keratome its insertion and withdrawal should be deliberate, on a plane with the iris. If the handle is too far forward the tip will catch the iris, dragging the iris away from its root, causing pain and hemorrhage, should the forward movement be persisted in, the operator endeavoring to make his incision wide enough, the zonula and lens may be injured. In withdrawing the keratome is when most errors are committed the handle is carried far forward allowing the tip to scrape along the anterior capsule of the lens and the iris is forced backward, causing undue pressure on the zonula at the same time that the wound gapes, permitting an expulsive loss of aqueous. A knife incision when the anterior chamber

is shallow is safer, although even here care in cutting out slowly should be observed. In these cases an iridectomy ab externo is an excellent procedure.

The width of the incision too should be enough to allow easy instrumentation for the iridectomy and not large enough to encourage too rapid a loss of aqueous or a large prolapse of iris or even the ciliary body.

The Iridectomy—Von Graefe thought that "a large portion of the iris should be excised, the more intense the symptoms the more extensive the excision." In the cases considered for this operation today in the early stage, one is apt not to follow this dictum, removal of the iris at its root establishing a free communication between the anterior and the posterior chambers, and the reestablishment of circulatory equilibrium make it unnecessary to form a large coloboma which gives a most annoying dazzling from too much light entering the eye. The iris forceps should be slid over the posterior lip of the wound closed and opened only 2 mm over the sphincter of the iris, which it grasps lightly. Attempts at entering the wound with conjunctiva, of the anterior lip over the tip of the forceps, or attempts to grasp the iris by tipping the forceps strongly backward may produce a dialysis of the iris, break the zonula or dislocate the lens. The iris should be drawn out slowly until just taut, cut through the sphincter on one side and then gently torn from its base from 3 to 4 mm and again cut. Continued dragging upward may tear the iris entirely out or leave the iris pillars firmly incarcerated in the angles of the wound.

Toilet of the Wound—The iris pillars should be stroked easily or floated by saline solution into position, from periphery toward the pupil no pressure being used. The conjunctiva should be placed in position and sutured if necessary, so as not to allow it to slide down and buckle into the wound a deep vascularization taking place from this faulty position of the conjunctiva.

Some surgeons believe that atropine instilled after an iridectomy is superfluous and wait for iritic signs and symptoms to arise before so doing. It is essential to make this instillation of atropine a routine, unless for any reason, as in peripheral iridectomies, for forty-eight hours the pupil is to be drawn down with miotics for the purpose of keeping the iris out of the wound. A traumatized iris is bound to react by slowing up of the blood stream the contents of the blood vessel being exuded into the area, blocking the filtration angle, or leading to an infection, unless studied with a slit lamp under magnification and measures adopted accordingly. This is not appreciated until irreparable damage has been done or at least started the stimulation of cellular proliferation going on to wound repair.

The Lagrange⁵ sclerecto-iridectomy is an operation as is the Elliot trephining and the Holth⁶ iridencleisis procedure, to establish extra-ocular pathways for the drainage of intra-ocular fluids. The object of this operation is an excision of a portion of sclera in the filtration angle under a conjunctival flap, sectioning the scleral spur, opening up the suprachoroidal space, and excision or not of a portion of the iris.

⁵ Lagrange P F On the Production of a Filtering Cicatrix in Chronic Glaucoma Ophthalmoscope 5 467-472 (Sept 1) 1907 On the Filtering Cicatrix in the Cure of Glaucoma ibid 6 363-374 (May 1) 1908

³ Gradle H S A Critique of Glaucoma Operations Am J Ophth 18:730-735 (Aug) 1935

⁴ von Graefe, Albrecht Arch Ophth 4 127 1858 New Sydenham Soc. Proc., 1859 p 368

In the original operation, when a knife incision is used with a removal of the scleral segment by scissors or knife (Kalt) cut or Vacher punch, the least amount of trauma to parts involved is done and the sclerectomy covering is usually adequate. This too can be said of the modified operations with the keratome, although here the incision into the anterior chamber is further forward, not sectioning the scleral spur.

The errors in technic with the incision occur in making the incision too far back, so that the ciliary body is injured, in making the sclerectomy too wide and too long (as when first advised it was 7 by 1 mm). The ciliary body and processes bulge forward into the wound. Should the sclerectomy be too narrow, much less than a millimeter in width, it closes over from episcleral connective tissue growth surely and rapidly.

This operation offers a nicety of judgment and skill to be demonstrated only by a surgeon accustomed to doing it.

The iridectomy, whether complete or peripheral, should be such as not to leave iris incarcerated in the wound. Lagrange and Holth insisted on this, although later Holth found that iris incarcerations were of aid in forming a filtering cicatrix. He later devised and continues to carry out the iridencleisis procedure. It might be said here that the iridodialysis done by Spratt² can be done in these cases, especially when an active iris can be controlled with miotics long enough to have the aqueous go directly through from the posterior chamber into the peripheral anterior chamber and into the fistulous opening. When this does not occur, the iris persisting to prolapse or, when the iris is atrophic, the root of the iris should be excised, leaving the iris sphincter intact for whatever miotic action is necessary, avoiding the disturbing coloboma.

Lagrange always insisted on early massage in these cases keeping the tension between 12 and 25 (Schiotz) if possible. As with the trephine, if the sclerectomy is too large, hypotony with its ensuing degenerative changes may follow.

The toilet of the wound is done with the same care as in the therapeutic iridectomies with a suturing of the conjunctiva and the instillation of atropine. One is reminded that careful observation of the reaction of the iris to injury subsides in a few days, when the atropine can be discontinued. When continued longer it may act as an irritant, defeating the object of its instillation.

The trephine operation in this country and in many European eye clinics is the operation most used for filtering purposes, for chronic uncompensated (late stages) compensated hypertensive cases and infantile types of glaucoma. The first fault likely in carrying out this operative procedure is in making the conjunctival flap.

Colonel Elliot says

- 1 Fashion a wide-based conjunctival flap avoid injury of the subjacent tissues as much as possible whilst raising it
- 2 Carry the dissection as low as possible.

The trauma involved in securing this conjunctival flap perhaps not too large if not done lightly and speedily with avoidance of pressure on the globe may cause a delay in the formation of the anterior chamber. This too may follow a buttonholing of the flap.

Colonel Elliot makes a strong point of splitting the cornea, not cutting it, and Calhoun¹ believes that this should be properly done to ensure the placement of the trephine well on the cornea.

If the conjunctiva with subconjunctival tissue and episcleral tissue is dissected well onto cornea to the limit seen in the microscopic sections—done cleanly leaving no episcleral tissue to allow the trephine to slip about—it would seem that splitting the cornea is an added trauma, with additional raw edges and subsequent irritation.

In the aged little subconjunctival tissue is present, it is essential that episcleral tissue from the insertion of the superior rectus muscle should be taken down with the conjunctiva to avoid a thin conjunctiva over the trephine opening, avoiding a fistula or subsequent infection, should a virulent conjunctivitis supervene at any time. Case reports show that this may happen and yet several writers have traced this possibility to an iris strand in the wound, keeping up a local irritation or a quiet iritis which leads on to an infection.

Complications are believed to follow the use of too large a trephine—2 mm—too free drainage followed by hypotony. Colonel Elliot uses nothing else and has had no bad results or regrets from using this size trephine. My experience with the 2 mm trephines was that the conjunctival flap seemed to lie flat on the opening and even be drawn into it from the hypotony that ensued, forming an excellent bridge for newly formed connective tissue to grow under it. Ciliary body, ciliary processes, vitreous and even lens have been seen in these wounds. The usual size trephine is 1.5 mm, which, unless sharp, requires much effort to make an opening when the latter is made, it is ragged and often incomplete and leads to early wound closure from connective tissue formation. No scleral hinging is advised for this reason. A suture may be placed in the segment to be excised with the ends run through the hollow trephine shaft. The trephine advised and used by Walker is good for this purpose. The corneoscleral disk if lost need not worry the operator, and usually the escape of aqueous and bulging of the iris into the wound keep the disk out of the anterior chamber, especially if the trephine just cutting through the corneosclera is gently and slowly removed.

The site of the trephine opening by its author is half cornea and half sclera. Some writers believe that it should be well forward in the cornea, but most surgeons believe that cornea tissue proliferates easily closing the opening. Others believe that this occurs if the opening is scleral in position.

A number of men lay the failure of a trephine opening to remain open permanently to the fact that the corneoscleral disk has not been removed cleanly. Sections of the disk should be completely lined or at least partly lined by Descemet's membrane. Uninfected wounds of the corneoscleral region, when bathed by aqueous humor manifest no tendency to the development of granulation tissue and remain open indefinitely.

The complications of iridectomy are the same as those mentioned in the two previous operations, perhaps more so, as the area of operation is limited.

Errors are committed in simply cutting off the top of the iris as it is bulging into the wound leaving the root of the iris to swing into the wound later in cutting away enough iris so that when replaced it is not well away from the wound margins, in reaching for an iris which does not prolapse readily or at all. It is in the latter attempts that the zonula is broken and vitreous presents.

In the replacement of the iris gentle massage on the cornea or a stream of physiologic solution of saline

chloride may float it into place. All writers condemn the use of the spatula in the trephine opening as a source of injury to the lens and zonula.

Suturing the conjunctival wound, instillation of atropine when the iris has been traumatized and the use of massage in certain cases in which filtration is slowed up temporarily by a blood clot or iritic exudate is strongly advised. With the restoration of the anterior chamber and more or less normal ocular fluid, failure of drainage through the opening, and closure of this fistula, or absorption by way of the conjunctival and episcleral vessels is unlikely.

Iridencleisis—This method of extra-ocular drainage, popularized by Holth, is becoming more used in this country for the same type of cases for which the Lagrange and trephine operations are done. In the secondary types following cataract operation it has seemed to be of help.

The same steps as in therapeutic iridectomy are carried out with the modification of Holth, using a punch excision of a millimeter strip of sclera in the filtration angle. The first cut in the iris is as mentioned, cutting the iris meridionally through the sphincter, with the resultant temporal or nasal portion of the iris placed under the conjunctiva as a tube or flattened out exposing the epithelial layer under the conjunctiva. This represents an interposition of material between the cut ends of Descemet's membrane, over which the corneal endothelium does not grow. When the iris has become atrophic with loss of much of the pigment, filtration seems to stop with the formation of connective tissue from both the iris and the surrounding episcleral tissue.

Spaeth has shown that the lining of the filtration scar is made up of iris epithelium. Verhoeff earlier thought that the iris tissue atrophied and became stretched and cracked in areas allowing the aqueous to flow into the separated fine connective strands making up the rest of the cicatrix.

Hemorrhage into the anterior chamber is often prevented, Gjesing believes, if a retrobulbar anesthesia with epinephrine is used. He has also said that iridencleisis offers no more lasting good result than other operations for glaucoma.

Infection through the filtration area as well as sympathetic ophthalmitis has been reported.

Cyclodialysis—This is Heine's operation for the intra-ocular drainage of the aqueous. Instead of a keratome the sclera is usually incised with a knife underneath a conjunctival flap 4 to 5 mm from the limbus. The ciliary body may be cut into, causing profuse hemorrhage. The separation of the ciliary body from the sclera by breaking through the sclera, may be done so roughly that injury to the ciliary body later sets up an iridocyclitis. An iridectomy may be done before or even afterward, when the root of the iris is broken away from its peripheral adhesion. The breaking up of the suprachoroidal trabecular by the spatula is of help in opening up the suprachoroidal space but if persisted in too violently more than 13 mm behind the limbus damage to the emissaria and contents the lymphatics and cortex veins may occur.

Early failures of this operation were due to a limited opening from 2 to 3 mm, avoiding a large dialysis of the ciliary body. Quick replacement followed the

return to increased ocular tension. A wide dialysis allows the ciliary body to sag, and the pull of the ciliary muscles, if not atrophied, both meridional and circular for a time at least keeps the suprachoroidal space open. Aqueous interposed between the raw surfaces prevents adhesions from forming. In many cases, as soon as the tension begins to rise again, these parts are pushed together, shutting off drainage.

It may be a temporary procedure much like repeated anterior sclerectomies in secondary glaucoma cases due to an iridocyclitis. It has been said that interference with vascular and nerve supply to the ciliary body is such as to decrease the supply of aqueous formed giving a satisfactory result as far as hypertension of the eye is concerned. Increased ocular tension after a cataract operation seems to do favorably with this operation.

CONCLUSION

The causes of failure in operations for the control of intraocular tension appear to be due to

- 1 A well advanced ocular pathologic condition at the time of operative intervention
 - 2 The operative procedure not being the best one, in view of the tissue changes present
 - 3 Definite errors in operative technic and after-care
- 20 East Fifty-Third Street

ABSTRACT OF DISCUSSION

DR HARRY S. GRADLE, Chicago. In all forms of glaucoma, the object of the surgeon is to restore a status of normal pressure equilibrium. The pressure equilibrium of the eye has a coarse balance in the form of the choroidal reservoir and a finer balance wheel in the aqueous humor. The ophthalmic surgeon can influence in any eye with a normal or an abnormal tension the outlet of the aqueous alone. He cannot influence the total fluid content of the eyeball; he cannot influence the formation of the aqueous; he can influence only to a certain extent the elimination of the aqueous from that eye. There are three possible ways in which that can be performed. The normal elimination may be restored through the chamber angle and the canal of Schlemm; a new passage may be opened between the ciliary body and the sclera whereby the aqueous can filter into the suprachoroidal spaces and there be absorbed; or an extra-ocular drainage may be formed for the aqueous. The type of operation to be employed must depend on the eye in question and it is extremely difficult to lay down any set rules. If firm anterior adhesions between the iris root and the posterior surface of the cornea have been formed it is a physical impossibility to open up the chamber angle to restore the normal drainage of that eye. No spatula and no knife ever devised can free the chamber angle adhesions so that the chamber angle may again be opened to normal function. The formation of a new intra-ocular drainage path as exemplified by the cyclodialysis operation, is not a difficult procedure, but the application of that principle is limited to a small number of cases. It is obviously impossible for a pathway to remain open between the ciliary body and the sclera if there is an excessive amount of pressure on the other side of the ciliary body. In other words if the pressure within that eyeball is high it is entirely impossible for a cyclodialysis to be successful. The final type of operation is that of extra-ocular drainage. Now which types are to be employed and why is success attained in some and not in others? It stands to reason that the cases in which a real iridectomy may be performed for the purpose of opening up normal drainage paths are extremely limited in number. The acute uncompensated glaucomas and some of the forms of secondary glaucoma. The greatest difficulty lies in determining what operative procedure to use in the compensated forms of glaucoma. Here in the last year a very definite clue has been obtained in the chamber angle examination of Otto Barkan who has shown whether or not one can hope to open a

pathway into the suprachoroidal spaces and thereby produce intra-ocular drainage, or whether the angles are so closed up and so pigmented that it will be necessary to do a type III operation

DR. CHARLES N. SPRATT, Minneapolis. An important observation by Thomas Henderson is to be found in the *Ophthalmic Review* of 1907. In a series of thirty-three eyes on which iridectomy had been done, he reports a stump of iris 1 mm in width after the flap operation. After the von Graefe section this iris stump averaged 0.75 mm. It seems to me that the iris tongue is the problem in all glaucoma operations. For twenty years I have done both the Lagrange and the trephine operation, the former being preferred because it is easier. It is difficult to make an iridectomy without leaving considerable iris base when operating through a trephine opening. Six years ago I combined the Lagrange operation, done beneath a pocket flap, with an iridodialysis instead of iridectomy. This was following a suggestion of de Wecker in 1894, who combined anterior sclerotomy with iridodialysis. The orbit is injected with procaine hydrochloride and a suture is placed in the superior rectus for fixation. An incision is made in the conjunctiva 10 mm above the limbus and a pocket flap is made as in the cataract extraction. A mattress suture is placed in the conjunctiva before the eye is opened. The suture adds to the safety of the operation and is more easily placed at the beginning than at the end. A typical Lagrange is next made with a narrow von Graefe knife. The flap of sclera is incised with scissors or, if one prefers, with a punch. The iris is grasped at its periphery with iris forceps, which are then pushed forward toward the center of the pupil. The iris separates at its attachment at the ciliary body, forming a dialysis. Thus no iris stump is left to block the wound and there is a round pupil. The objections to this operation are, first, hemorrhage, and second, possible injury to the lens. The latter does not take place as the iris, held by the forceps, protects the lens and any blood is rapidly absorbed. I have now records of ninety-six eyes that have been operated on by this method and these have been under observation from two months to six years. I have had five failures, that is, the tension has not remained down. Some of the eyes in which the tension has been lowered have shown loss of visual field and deterioration of the central vision.

DR. PHILIP D. O'CONNOR, Chicago. In making the keratome incision the tendency is to go too far forward in the cornea or to enter the anterior chamber at such an angle that there is a flange of cornea posteriorly. In either case it is impossible to do a proper iridectomy. This cannot be emphasized too much. These errors in technic can be avoided by making the incision with a knife as in the Lagrange operation. I should like to ask Dr. Weeks if he uses a subconjunctival injection of procaine before he makes the conjunctival flap in doing the trephine operation. I have made the flap with and without the injection. It seems much easier and the results better when the subconjunctival injection is made. There is less trauma, more episcleral tissue is on the under surface of the flap, the junction with the cornea is more clearly defined, and there is less danger in buttonholing the flap. Should splitting of the cornea be necessary the extent of the splitting is lessened, especially if a 15 mm trephine is used, as advocated by Dr. Weeks.

DR. WEBB W. WEEKS, New York. The indications for the type of operation called for are judged by the appearance of each eye viewed microscopically before and after operative procedures. These studies indicate that, in primary acute congestive glaucoma and in early chronic congestive glaucoma not relieved by local or general treatment when anterior proliferative synechiae have not had time to organize the basal iridectomy often permanently relieves the increased ocular tension. In the chronic glaucoma cases of some duration, in which the anterior proliferative synechiae are definitely organized into the connective tissue formation and permanent damage has occurred to the filtering spaces of Fontana, and in many cases of secondary glaucoma the filtering operations, namely, the trephine, the Lagrange, the iridencleisis and the cyclodialysis procedures seem to be definitely indicated. Filtering operations, even the Elliot trephine operation, require a massage of the eyeball sometimes from the very first day after operation to dislodge a plug of exudate or hemorrhage, so that no irritation will occur sufficient to start a cellular proliferation and subsequent closure of the filtering wound by a cicatrix.

Clinical Notes, Suggestions and New Instruments

BLACK SPUTUM ANTHRACOSIS AND SILICOSIS IN THE SAME PATIENT

HAROLD C. LUETH, M.D., EVANSTON, ILL.
V. A. GANT, M.S., AND DON C. SUTTON, M.D., CHICAGO

Pigmentation of the lungs following the inhalation of air containing small carbon particles is a well known condition. Anthracosis is so commonly asymptomatic that it is generally regarded as a harmless pathologic curiosity. The inhalation of silica dust, however, is responsible for definite symptoms and marked lung changes. Recently we were afforded the opportunity of observing a patient in whom the harmlessness of anthracosis and the marked symptomatology of silicosis were demonstrated. The expectoration of large quantities of black sputum with the clinical observations of silicosis made this case unusual enough to report.

REPORT OF CASE

F. K., a white man, aged 56, entered ward 15 of the Cook County Hospital Feb. 5, 1935, complaining of cough, extreme fatigue on exertion, and occasional night sweats. Early in December he "caught cold," which condition lasted for ten days, although the fatigue and the exhaustion persisted. The slight cough became worse, so that two weeks before admission he expectorated large quantities of black sputum.

As a young man he worked in the coal mines near Oklahoma City for twenty-five years without any impairment of health. During an acute corvza he occasionally saw small black flecks in the sputum. As the result of a strike he left the mines in 1925 and came to Chicago seeking employment. The next four years he worked as a shipping clerk and was free from illness. Adverse business conditions left him without employment for six months. Then he accepted a job in a machine shop cleaning castings with a compressed air sand blast. Celluloid eye shields were the only protective devices offered. He soon developed a dry cough, the common complaint of the fellow workmen. After nine months this cough was productive, with the expectoration of black sputum. Sharp pleural pains, fever, hemoptysis and weakness followed, forcing him to bed for six weeks. At the end of this time all symptoms had disappeared except an occasional expectoration of black sputum. When he returned to work he was transferred to the paint department. This new work suited him better and he continued at it for a year without any illness, until discharged for economic reasons. During the first winter of unemployment (1931-1932) he had a typical acute bronchitis with fever, cough and weakness, which provoked a return of the black sputum. It lasted a month. After this the occasional cough with the expectoration of light gray sputum was the sole complaint. There were recurrences of the acute bronchitis during the next two years but they usually subsided in from four to eight weeks. However the cough became chronic and the sputum darker in color with other alarming symptoms so that he entered the hospital.

On admission the patient was slightly emaciated and did not appear acutely ill. Both cheeks were flushed and the buccal mucosa and the pharynx were red. The chest was symmetrical and slightly enlarged and the expansion was moderately diminished. Respirations were shallow and frequently interrupted by paroxysms of coughing. Dulness was present over both bases, tactile fremitus was diminished and there were few moist rales throughout the lungs. The blood pressure was 122 systolic, 84 diastolic. Cyanosis was absent. The heart, abdomen and extremities were normal.

Blood urine and gastric tests were normal. The sputum was repeatedly negative for tubercle bacilli.

Röntgenologic examination of the chest on entrance showed dense infiltration of the upper halves of both lungs with several well defined oval areas in the lower parts. Three weeks later a second series of plates was taken to exclude the possibility of a metastatic malignant condition. The lungs were and the gastro intestinal tract were normal. The oval areas were still present although considerably smaller. Old calcified hilus glands were seen and a fine reticular infiltration of distinct honeycomb markings was clearly discernible. There had been sufficient clearing of the original process to demonstrate silicosis.

X-ray films taken a year later showed a slight clearing of the fibrosis of the lungs

A bronchoscopic examination was made by Dr S J Pearlman of the ear, nose and throat department. He reported uniform black pigmentation of the entire bronchial mucosa

The patient was kept in bed and given a high caloric diet. During the first week there were periods of fever to 99.4 F, and after that none. His appetite returned when he was afebrile and he soon regained his weight and strength. The second week after admission the dullness disappeared and in the third week the tactile fremitus returned to normal. Except for an occasional moist rale that disappeared after coughing, all his symptoms and physical abnormalities had subsided by the end of the fourth week. The patient's improvement was so great that it was difficult to remain in the hospital long enough for the collection of the last sputum specimen. He was discharged five weeks after admission, entirely well except for an occasional expectoration of light gray sputum. A year later, when last reexamined, the same condition persisted.

The amounts, color and character of the sputum were recorded daily. It was collected in the usual paper cups at first, but the large quantities made this method impracticable. A 500 cc. wide mouth glass bottle was found more satisfactory. From 175 to 250 cc was expectorated daily, and these fluctuations could be accounted for by the careless disposal of mouth rinsings. As the first samples studied contained many black flecks, the possibility of a soot contamination was considered. To obviate these objections the following procedure for the collection of sputum was instituted. The patient gargled and rinsed his mouth with physiologic solution of sodium chloride at frequent intervals. Usually he was able to rinse his mouth just before a paroxysm of coughing. The rinsings and other materials were put in a separate container and destroyed. He was instructed to expectorate only such sputum as he believed came from 'deep down in his lungs' in the special glass jar.

A jet-black color and limp consistency of the sputum were constantly observed. When it was allowed to stand in a tall glass cylinder it would stratify into three layers: a yellowish black lower, a viscid jet-black middle, and a foamy white upper layer. The middle stratum occupied more than three fifths of the volume, the remainder was equally divided between the other two. Very little of the black material would settle on standing. In fact, some of the weekly specimens stood for six weeks without any appreciable precipitation. Microscopic examination showed that the lower layer consisted of numerous degenerated leukocytes, bacteria debris and carbon particles. The middle stratum contained from 3 to 15 polymorphonuclear leukocytes per high power field with numerous (4 to 20) black masses. These particles were irregularly shaped fragments of different dimensions up to 10 microns. None of them were contained in the leukocytes. Their black shiny appearance offered a striking contrast to the pale leukocyte when stained with aniline dyes.

Chemical examination of the black particles of the sputum was performed as follows. Filtration through coarse filter paper was unsuccessful. The thick viscid sputum would pass through several thicknesses of gauze fairly well, leaving a small black residue. This was suspended in water and tested further. It was insoluble in distilled water, acetic or hydrochloric acids or dilute alkalis, either hot or cold, also in ethyl alcohol, acetone, sulfuric ether or benzene. It was readily combustible and was burned completely over a free flame. From these tests the black material was concluded to be carbon.

Weekly samples of sputum were collected for quantitative determinations. The same procedure was used, except that a half gallon jar was needed. Only three weekly specimens were obtained during the patient's hospital stay. The last weekly specimen was collected a year later by the patient at home.

A survey of the literature failed to reveal any method for the estimation of carbon in sputum, but there were a number of methods for the determination of carbon in the lungs. Hirsch¹ suggested a colorimetric method. Known quantities of finely divided toluene soot were suspended in liquid petrolatum and compared with suspensions of dried lung tissue after antiformin digestion. Since the size, density, degree of blackness and purity of the carbon particle determines its colorimetric index, we favored a gravimetric estimation of carbon.

1. Hirsch E F. A Method for Graphic Demonstration of Foreign Inorganic Matter and Carbon in the Lungs. J A M A 66:950-51 (March 25) 1916.

Following the method of Klotz,² the material was digested three times with 75 per cent antiformin, then alcohol was added and the mixture was centrifugated. The material was again digested with 10 per cent hydrochloric acid and centrifugated. Subsequent washings with acid alcohol and ether were tried without success for the following reason. Digestion with antiformin at 40 C for several weeks did not destroy an appreciable amount of the organic matter other than carbon, and only a small percentage of the black material present could be separated by repeated and lengthy centrifugating, the bulk of the carbon remained in colloidal form in the greenish black supernatant liquid. At this point attempts to filter out this carbon by gravity and suction with the finest grades of filter paper were unsuccessful, indicating further that the black material was in a colloidal state. In view of this fact the procedure was modified. The solutions were acidified with concentrated hydrochloric acid and stirred vigorously, thus breaking up the colloid. The mixture was not heated at this point because free chlorine from the antiformin in the presence of hydrochloric acid and heat would have oxidized some of the carbon. This material was washed into 250 cc. centrifuge bottles and centrifugated. The mass in the bottom of the bottles, which consisted mainly of coagulated protein, carbon particles, a small amount of inorganic salts and some fat, was washed repeatedly with distilled water, alcohol and ether respectively, with subsequent centrifugating. After washing the material into a 400 cc. pyrex beaker with 10 per cent hydro-

chloric acid it was digested over a free flame until the coagulated protein was dissolved. The black insoluble residue was allowed to settle out and washed several times with hot distilled water by decantation. The residue was then digested over a free flame with 200 cc of a 10 per cent sodium hydroxide solution and filtered through a No 42 Whatman ashless filter paper previously treated with the alkali, washed, dried and weighed. The paper and residue were washed free from alkali, dried and weighed. The difference was recorded as total carbon plus any acid insoluble salts and silica. The filter paper and residue were ignited in a tared platinum crucible and the ash was subtracted from the dry residue originally weighed on the filter paper, the difference in weight being recorded as carbon. In each case the amount of ash was practically negligible, ranging from 2 to 0.9 mg of which hardly any was volatile with hydrofluoric acid. This indicated that the very small amount of silica present was of no toxicologic significance.

Four specimens of sputum each representing as closely as possible the total expectoration from the lungs for a period of one week, were submitted to the laboratory for carbon and silica determinations. The specimen representing the first week was so black that it might easily have been mistaken for ink instead of sputum. The second week it was less black and the third week a grayish black. The fourth sample collected a year later was dull gray.

COMMENT

From the history and clinical examination in this case, the following explanation is suggested. The patient was exposed to coal dust for twenty-five years and in the next four years

2. Klotz O. Pulmonary Anthracosis. A Community Disease. Am J Pub Health 4:887-915 1914.

he was engaged in a nondusty trade. The resulting anthracosis was asymptomatic during that time. A relatively short exposure working with an unprotected sand blast was followed by an acute silicosis. The patient's history led us to suspect both pulmonary parenchymal and bronchial changes. The former has been described by many. Chapman³ reported a fatal case of acute silicosis with large amounts of gelatinous mucopurulent material in the trachea and bronchi, suggesting a fetid bronchitis. In our patient a short rest and a change of occupation were followed by a subsidence of symptoms, except the occasional expectoration of black sputum.

The patient then lost his job. He supported his family by odd jobs that frequently exposed him to wet and cold. In addition his dietary was greatly curtailed, since the family managed to live from his previous savings and irregular income for two years before they sought relief assistance. During this period he had repeated attacks of acute bronchitis and it is difficult to evaluate the factors of exposure and malnutrition. The bronchitis became chronic and increasingly larger quantities of foul sputum were expectorated, so the development of a bronchiectasis was assumed. Clinical examinations made while at the hospital confirmed these suspicions. Adequate postural drainage and a high caloric diet ameliorated these symptoms. The continued betterment for the next year while at home on a liberal diet and the avoidance of exposure (relief assistance) is also significant.

Any irritating dust in the alveoli of the lungs will provoke a catarrhal inflammation. There is considerable controversy concerning the origin and nature of these cells, but they are generally called "dust cells." They have been identified as endothelial cells, alveolar epithelial cells or mononuclear leukocytes.⁴ Some of the "dust cells" are phagocytic and engulf irritating dust particles. The body reacts differently toward coal dust than toward silica dust. Mavrogordato⁵ believes that the "dust cells" which contain carbon are digested or undergo autolysis, leaving the carbon extracellular. Silica, on the contrary, remains intracellular, the dust cells remaining in groups and later stimulating fibrosis. Silica appears to protect the "dust cells" from autolysis and lymphatic digestion. It would appear that the acute silicosis in this case liberated the extracellular carbon. Recurrent attacks of bronchitis probably provoked a similar reaction.

A SIMPLE INEXPENSIVE HEAT LAMP

FRANK H. KRUSEN, M.D., ROCHESTER, MINN.

Nearly every physician uses some form of heat lamp as a routine in his office practice. Many practitioners are unfamiliar with the fact that various sources of infra-red, or heat, rays differ in their ability to produce heat penetration. While none of the heat lamps used in medical practice produce very marked penetration of heat, those which contain an "infra-red unit" (heated coil or heated carborundum plate) produce the least penetration. These so-called infra-red units differ not at all in their output of therapeutic heat from the heat elements used in household heaters, which can be obtained for a few cents at any hardware store or even at the five and ten cent store. The only difference between the household heater and the infra-red lamp used in the physician's office is that the former has a wider pan or reflector, which is shaped like a soup plate and which diffuses the heat through the room, while the latter has a cup-shaped reflector which concentrates the heat at a distance of approximately 2 feet (60 cm.) from the lamp. The infra-red units produce a more marked surface heat sensation than do the luminous bulbs, which are also used in the cup-shaped reflectors seen in physicians' offices.

Coblentz¹ in a recent report on the use of light therapy in Europe pointed out that "instead of the fancy expensive lamps sold to the medical profession numerous 500-watt electrical

lamps (in common use for heat lamps and costing only the equivalent of a few cents) are used by individuals. For this purpose the lamps are provided with clamps for attachment to the beds."

The purpose of this note is to suggest to American fellow practitioners that any simple, well polished cup shaped reflector attached to a small clamp, as shown in the illustration, in which reflector is placed either a simple heat unit such as is used for

Simple inexpensive heat lamp which may be clamped to a chair or bed

the ordinary household heater or, interchangeably with this a 250-watt or 500 watt tungsten or carbon filament luminous heat bulb, is an entirely satisfactory source of heat energy for local application of heat to the surface of the body. The luminous lamp produces heat radiation which penetrates to greater depth than does radiation from the infra-red unit, and the heat energy does penetrate to the capillary blood-bearing area of the skin and does produce hyperemia. The luminous lamp will be found of more usefulness than the infra-red heat element for producing hyperemia, whereas the infra-red unit, penetrating

to less depth, will produce more heat sensation on the surface when this is desired. The various parts for an entire unit of this sort, a reflector, a clamp (which can be attached to the bed or to the back of a chair), a connecting cord, a luminous heat bulb and an infra-red heat element can be purchased almost anywhere in this country for approximately \$4.

Special Articles

THE PHARMACOPEIA AND THE PHYSICIAN

AN INTRODUCTION TO A SERIES OF ARTICLES ON
THE USE IN THERAPY OF PHARMACOPEIAL SUBSTANCES

WALTER A. BASTEDO, M.D., ScD
President of the United States Pharmacopeial Convention
NEW YORK

This is the first of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed

Fundamentally the physician is a therapist, for he must treat his patients. In his therapeutic armamentarium drug remedies assume a large importance. It follows that any method for the selection of the best drugs and the establishment of standards to ensure their quality, purity and strength must appeal to him. Hence his interest in the Pharmacopeia.

A series of therapeutic articles is being prepared for publication in THE JOURNAL. It is sponsored by the U. S. Pharmacopeial Convention through its Revision Committee, in cooperation with the editor of THE JOURNAL. Each subject is to be dealt with by one or more authorities, and the emphasis throughout will be on methods of treatment. While it is hoped that this means the physician's attention will be directed to the high quality of the drugs and preparations of the Pharmacopeia and their ability to meet his most exacting needs in therapy, other measures of treatment

also be considered. The articles will include advice on methods of administration and the writing of prescriptions for the remedies recommended.

THE PHARMACOPEIA

In 1820 a group of physicians under the leadership of Dr. Lyman Spalding met in convention and compiled the first Pharmacopeia of the United States. Since then a similar group has met every ten years to revise this work. But, because of scientific advances, technical help became necessary and, because of growth in the number of delegates to the convention, the actual work of revision had to be delegated to a limited number. So today the Revision Committee of the United States Pharmacopeia is composed of fifty men who rank high among contributors not only to biology, pharmacology, serology, therapeutics and clinical medicine but also to botany, pharmacognosy, inorganic chemistry, organic chemistry and practical pharmacy. They serve without pay, for only on such a basis could the talents and continued interest of such men be commanded.

Of this Revision Committee a Subcommittee on Scope, which includes eighteen physicians, has had the duty of determining what substances and preparations should be admitted to the new Pharmacopeia. To the list in the previous Revision it has added fifty-eight drugs and preparations, fifty-four of which are therapeutic agents. But as the trend in therapeutics is not for more drugs to be used in a shotgun manner but for fewer and better drugs to be employed with definiteness, it has deleted 119 articles previously official. It has based its selection on therapeutic merit together with the extent of use in prescriptions, and in determining the latter it has profited from several prescription surveys made in various sections of the country.

The physician has a twofold interest in the Pharmacopeia. Its standards for the drugs and preparations that it recognizes become legal under the Food and Drugs Act, and as a consequence the prescribing of its drugs and preparations gives the physician the best assurance that these will have the quality, purity and strength desired. In addition the titles in the book have been selected from among the available nonpatented and nonsecret remedies by a group of able physicians who have given repeated and careful study and discussion to the therapeutic claims for each remedy. Furthermore, before final decision, a primary list of the drugs selected for admission or deletion was published in the medical and pharmaceutical journals of the country, and the resulting suggestions and criticisms were given serious consideration.

The physician who prescribes U. S. P. remedies can rely on their quality and their applicability in therapy. If he prescribes patented articles he may be chagrined by discovering that his patients renew their prescriptions and treat their acquaintances by buying his prescribed articles by name over the druggist's counter.

With regard to the remedies that he has been employing and does not find in the present Pharmacopeia, the physician must realize that these have been omitted as the result of extensive research which the physician himself would be unable to make. Indeed, he may feel grateful to the revisers for discovering for him that there are reasons for not considering these remedies of the highest rank. Some of the former standbys of the profession have dropped largely from use. However, the physician who has become accustomed to their employment and desires to continue them may still be

assured of their legal standardization, for most of them have been transferred to the National Formulary, which, like the Pharmacopeia, is official under the Food and Drugs Act.

The physician may inquire why a number of recently introduced remedies of high merit are not in the Pharmacopeia. The reason is that they are patented. The Pharmacopeia cannot adopt legal standards for a patented article, for the patentee is the sole arbiter for the standards of his patent. The new remedies of this class are given full consideration in the American Medical Association publication *New and Nonofficial Remedies*. If still deemed worthy when their patents expire, these drugs may receive prompt pharmacopeial standardization through the issue of "interim revision supplements" to the Pharmacopeia, instead of awaiting the next complete pharmacopeial revision ten years hence.

While the function of the Revision Committee is to revise, its methods for obtaining accurate information must result in far reaching benefits. It maintains the U. S. P. Vitamin Advisory Board, the U. S. P. Anti-Anemia Products Advisory Board and the U. S. P. Committee on Cardiac Drugs. All the members of these are of the highest rank in their respective fields.

The Vitamin Board has included Drs. Mendel of Yale (recently deceased), Sherman of Columbia and Nelson of the government vitamin laboratory. This board works with the corresponding international group of the Health Organization of the League of Nations, and partly through its efforts the former multiplicity of vitamin standards has been reduced. It sponsors the standardized samples known as Reference Cod Liver Oil, which, with accurately estimated vitamins A and D and packaged under carbon dioxide gas, is for the use of research laboratories and manufacturers. With the cooperation of some twenty-six experts in this country and abroad the board is now working on the problem of vitamin B preparations.

The Anti-Anemia Products Board, composed of Drs. Minot and Castle of Harvard, Edmunds and Isaacs of Ann Arbor, and Palmer of Columbia, will devise and supervise tests for liver and stomach preparations and similar products. The Committee on Cardiac Drugs, under the direction of Dr. Henry A. Christian, will make bio-assays and clinical experiments to determine the selection and best methods for standardization of drugs that act on the heart.

The physician should be familiar with the official drugs and preparations but he does not need to add the Pharmacopeia to his library, for almost all of its text is concerned with tests for identity, quality and strength, and with methods of assay. But he should know that all current tests and assays have been considered, and that they have been accepted or rejected only after they have been checked again and again in various laboratories, for when accepted they must be able to stand in the courts.

By securing the American Medical Association's latest editions of "Useful Drugs" and the "Epitome of the U. S. Pharmacopeia and National Formulary," he can review the titles and scope and be sure that he is presenting the latest official drugs and preparations.

At the convention of 1820, Dr. Spalding said "It is the object of a pharmacopeia to select from among substances which possess medicinal power those the utility of which is most fully established and best understood."

Its value depends upon the fidelity with which

it conforms with the best medical knowledge of the day." These criteria have governed the Eleventh Revision of the Pharmacopeia, which became official on the first of June 1936. It presents a selection by experts from available drugs and preparations and its standards are the ones recognized in law.

33 East Sixty-Eighth Street.

THE ADMINISTRATION OF THE SYPHILIS CONTROL PROGRAM

R. A. VONDERLEHR, M.D.
Assistant Surgeon General U. S. Public Health Service
WASHINGTON, D. C.

NOTE—The article by Dr. R. A. Vonderlehr and the articles by Dr. Dudley C. Smith and Dr. Joseph Earle Moore which follow, are part of a symposium on the control of syphilis. The remaining articles by Drs. Arthur J. Casselman, John H. Stokes and N. A. Nelson, will appear next week.—Ed.

The provisions of the Social Security Act enable health departments throughout the country to strengthen all phases of public health work. These provisions should at the same time permit of a sound development of measures directed against syphilis. In developing state and local programs, health officers are prone to stress those portions which relate to the control of diseases the prevalence of which is now rapidly declining. Some consider duty to have been done by sponsoring the construction of sanitary privies and carrying on a fairly intensive immunization program against diphtheria and typhoid fever. The successful health officer of the future will be judged not only for his accomplishments in the prevention of the common acute communicable diseases but also for his ultimate attainments in minimizing problems detrimental to the public welfare. Progressive health officers have stressed the prevention of the venereal diseases and heart disease, mental hygiene and industrial hygiene for more than a decade.

Syphilis is at present one of the most prevalent of diseases. Its cause, the means of preventing it, and the economic loss and suffering due to it are well known. As the prevalence of other common communicable diseases decreases, additional funds should be made available and further attention given to this most serious of public health problems.

There are certain general administrative points which must be understood if syphilis control work is to be successful. First of all the disease is an insidious one and from the very beginning of the control program the need for a long-term project must be realized. Although success might be attained in a period of months against more acute communicable diseases, years will be required for the successful prosecution of work against syphilis. This fact and a realization of the uncertainty of the continual provision of funds for public health work in the past has undoubtedly been a deterrent to the development of the syphilis control program.

One of the chief reasons why greater success has not been attained in bringing syphilis under control is its unfortunate association with morality. Health officers

must take the lead in teaching the public to regard syphilis as a disease and not as a form of moral delinquency. The disease, like many others, is a communicable one and should be so considered by the health officer at all times. The fact that it is spread chiefly through sexual intercourse should be given no special prominence in the application of control measures.

In the general administration of syphilis control work, two factors are of importance: (1) the selection of a well qualified venereal disease control officer with a clear-cut understanding of his duties and (2) the relationship of the venereal disease control office to other activities both within and without the jurisdiction of the health department.

THE VENEREAL DISEASE CONTROL OFFICER

As in any activity, great personal interest in the specialty is an essential qualification of the health officer specially selected to undertake the control of syphilis. He should be well trained in the practice of medicine and preferably experienced in general health work. He should spend a period of at least four to six months in a venereal disease clinic in order to become familiar with the routine management of syphilis and gonorrhea.

The duties of a properly qualified venereal disease control officer may be classified as administrative, advisory and cooperative. The administrative activities of such a specialist differ little in principle from those of any health officer. Work in the central office must be conducted efficiently. The administrator should know the capabilities of his personnel and the progress that is being made in the various subdivisions of his office. Because of the interdependence of the venereal disease control officer, local health officers and private physicians within the territory under his supervision, it is essential that as close cooperation as possible be established among these individuals. The degree of interest local health officers and private physicians take in the syphilis control program as well as their ability in this special work should be known. This is essential in order that the venereal disease control officer may encourage the cooperation and assistance of qualified workers in conducting the syphilis control program and either stimulate poorly qualified but interested physicians to greater endeavor or discourage them should their incomplete training, personality or lack of interest make them unfit for this type of work.

The successful administrator of venereal disease control work must have the ability to discriminate between poor and worth while projects. This is necessary because the problem is of such magnitude that many methods of attempting to solve the same problem are frequently offered. Limitation of funds and personnel make it essential that the most direct and efficient method be utilized to accomplish a given end. Astute judgment is required not only in the selection of projects but also in choosing personnel.

The advisory duties of the venereal disease control officer in the syphilis control program are manifold. Advice should be given only when requested but the progressive officer will be able to stimulate an increased demand for advice. The problems requiring consultation, which arise so frequently in venereal disease control work, relate to the diagnosis and clinical management of syphilis, the epidemiology of the disease and the personal behavior of the infected individual. The venereal disease officer should always act impar-

tially and with strict justice. He should deal with personal behavior only when necessary to prevent the spread of syphilis.

The necessity for obtaining the cooperation of the medical profession has already been mentioned. Besides the medical profession, cordial cooperation should be established with health departments in adjacent areas. Persons who are the source of infection, their contacts or defaulting patients may frequently move to an adjacent state, and it is necessary for the general welfare of the people in the entire country that individuals with communicable lesions be given adequate treatment wherever they may reside. Voluntary agencies are often of real assistance in developing a more intensive program and their cooperation should always be sought. Cooperation with other branches of government is desired, particularly the police department, in the management of recalcitrant cases, and the department of education in developing the informative program among citizens.

RELATIONSHIP TO OTHER HEALTH ACTIVITIES

Other Sections of the Health Department—The syphilis program under the venereal disease control officer should be coordinated with the communicable disease control work of the health department. This may be accomplished by organizing an office of venereal disease control, which should be very closely associated with the section of communicable disease control, or the syphilis control work may be developed in a subsection under the direct administration of the communicable disease control officer. In either case the venereal disease control work should be conducted as a separate enterprise and directed by a full-time health officer. The immensity of the problem, the highly specialized character of the work, and the peculiar dependence of the program on the physician in private practice make provision for an autonomous unit imperative.

The syphilis control program is likewise closely related to activities of the health department other than the communicable disease control section. For instance, the section on maternal and child care has frequent need for the assistance and cooperation of a specialist in syphilis control. This is true because the prevention of prenatal syphilis is fundamentally almost as important as the prevention of the transmission of early acquired syphilis.

The investigations of the Committee on Evaluation of Serodiagnostic Tests for Syphilis show an urgent need for close association between the venereal disease control unit and the laboratory of the health department. Laboratory tests have become more and more important in the diagnosis of syphilis during the past two or three decades. Because of their widespread and routine use it is essential that such procedures be as accurate as it is humanly possible to make them. The need for serologic check and clinical cross-check of serodiagnostic tests for syphilis becomes increasingly evident and it requires the careful guidance of an expert in syphilis to determine the reliability of a serologic test by comparison with the clinical observations.

The county or district health department is the basic unit of most state health departments. In many states a section of county health work exists. The unit cost of controlling the common communicable diseases will increase progressively as their prevalence decreases. Ultimately a point will be reached when it will no longer

be economically practicable to continue aggressive campaigns against such diseases. Optimum conventional procedure will be established. As this point is reached, additional funds will be made available for the solution of more difficult health problems. One of the first should be syphilis control work. For the reasons stated, county and district health departments will in the future show an increasing interest in the control of insidious communicable diseases, the prevention of degenerative diseases and problems of nutrition. Even now there is frequent need for cooperative and consultative work between the county or district health officer and a well trained venereal disease control officer, but at present a makeshift arrangement often exists whereby some health officer without special training in the control of syphilis and gonorrhea attempts without success to act in such a capacity.

The City Health Department—Perhaps no form of local health work under the nominal supervision of the state health officer has been more seriously neglected than that which has developed in municipalities, yet approximately 55 per cent of the total population of this country lives in cities. It is commonly assumed that most cities have an unlimited supply of funds for health work and that they are wholly independent of the state and surrounding counties. As a matter of fact neither of these assumptions is true.

A close relationship usually exists between the incidence of communicable disease within a city and in the surrounding territory. With syphilis this is particularly true, since under conditions of modern transportation visitors to the city are frequent and the disease may often be carried from urban to rural areas. The converse also is true. At the present time the tendency is for health organizations in the territory surrounding a city to neglect the syphilis control program. Infected individuals seek treatment in the municipality and are too often told that treatment is available only for residents of that city. If an investigation should be made it is certain that a serious condition would be discovered in and around the large cities of most states.

The duty of state and municipal health departments in the program against syphilis is plain. Instead of shifting responsibility and failing to provide adequately for the care of the infected individual, both state and municipal health departments should adopt a more liberal policy. The time has arrived when state health officers should establish a reciprocal arrangement to extend to rural and urban residents alike the full benefit of modern public health organization. An equitable agreement will require a real interest in proper coordination of the work and an unselfish devotion to the new principle. Municipal and county health officers must be urged to support and adopt this more liberal conception of duty.

The Social Security Act provides for the extension of public health facilities to all residents of the United States. No distinction is made within this law between residents of urban and rural districts. Municipal health officers should receive their share of the allocations for health work and in turn should make more liberal provision for the public health protection of all residents of the state in which they are located.

The Medical Profession and Voluntary Organizations—The interdependence of health officers and the medical profession in the successful prosecution of a

program against syphilis has been so frequently stressed that it is generally recognized. Not only is the cooperation of the individual physician required but the assistance of an aggressive organized profession is necessary. Health officers should respect the rights of physicians in private practice, who in turn should encourage and approve of the action of the health department in providing adequate treatment for all persons who cannot obtain private medical attention.

The aid of voluntary organizations interested in the improvement of social and economic conditions in the area is also of value. Cordial alliance should exist not only with social hygiene agencies but also with related social organizations and various economic and business groups.

A most helpful step is the adoption of the policy of appointing an advisory committee on the control of the venereal diseases. This committee should include at least the venereal disease control officer, a member of the local medical society, and a member from the voluntary organizations which take an active part in the welfare of the community. Progress will be made only by recognizing that united action is necessary.

FINANCING THE PROGRAM

Sufficient funds should be provided for the prosecution of syphilis control work. Provisions by the health department should be sufficiently liberal to permit the organization of an efficient program. Such a program may be defined as one which secures for the public adequate protection against the spread of this disease by infected individuals. The program should also include provision for adequate treatment of the individual patient by skilled personnel under maximum conditions of privacy.

No arbitrary system for the allocation of funds is known. The relative frequency with which syphilis occurs as compared to other communicable diseases is an important factor in the allocation of funds but it is not the only factor. It should be used as a measure of the adequacy of financial provision until a comprehensive control program has been developed. At the present time complete programs and adequate financial provision for carrying them out are very rare indeed.

CONCLUSIONS

1 The syphilis control program should be conducted by a special full-time venereal disease control officer as part of a separate section or subsection of the health department.

2 Great personal interest in the problem and special training in health work and the clinical management of syphilis and gonorrhea should be considered as the most important qualification of the physician who acts as venereal disease control officer.

3 The section or subsection for venereal disease control should coordinate and integrate its activities with other proper sections of the health department.

4 The state health officer should make a special attempt to unify syphilis control programs in adjoining cities and counties.

5 The cooperation of the medical profession and of voluntary organizations is of great importance in the development of syphilis control work.

6 Due regard for the importance of the syphilis problem must be given in financing the program.

PRACTICAL EPIDEMIOLOGY OF SYPHILIS

DUDLEY C. SMITH, M.D.

CHARLOTTESVILLE, VA

The epidemiology of a disease includes a study, first, of all the factors having to do with its transmission and, secondly, of all the means available for preventing its being conveyed to others. No attempt is made in this paper to present a complete discussion of the epidemiology of syphilis. Some medical measures practical in their application are outlined.

Syphilis is a rapidly spreading and widely prevalent disease. The United States Public Health Service estimates that there were 518,000 new cases of syphilis in this country in 1934. Syphilis is then rapidly spreading. These new cases added to the older ones certainly make it a widely prevalent disease. History shows, though, that at one time syphilis spread in a more wholesale fashion, affecting seriously by marked exter-

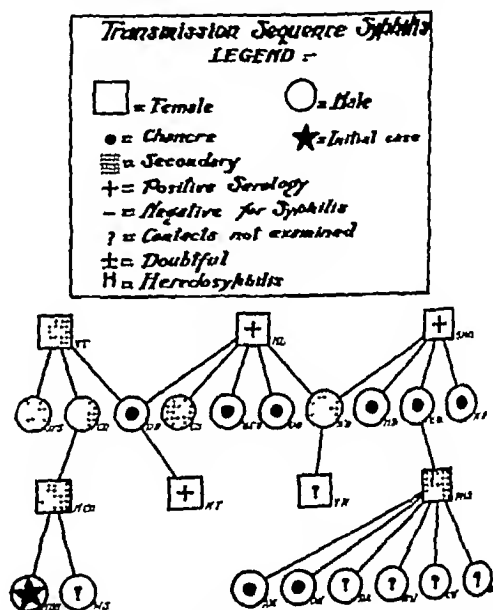

Chart 1—Result of tracing source cases and contacts beginning with a private male patient with a chancere. Twenty-five names were obtained; nineteen persons were examined and found to have syphilis; six have not been examined by us.

nal and clinical manifestations large populations. Now it spreads more insidiously but nevertheless surely. There is evidence that it still advances mainly by small epidemics rather than on an even front. This insidious attack along with the infection's association with sex and morals has hindered the application of known medical measures. Stokes¹ has said that syphilis in the human body is like an iceberg, nine tenths below the surface, and this is just as true when the disease is considered from the point of view of general distribution. However, it is possible by using the one tenth above the surface as signals to detect that which is submerged.

From the University of Virginia Department of Medicine, University of Virginia Department of Medicine, Charlottesville, Va. It was presented at the annual conference of the American Dermatological Association, Swampscott, Mass., June 25, 1936. Read in part before the Annual Conference of State and Territorial Health Officers with the Surgeon General of the U. S. Public Health Service, Washington, D. C., April 13, 1936, and at the annual meeting of the American Dermatological Association, Swampscott, Mass., June 25, 1936. ¹ Stokes, J. H. *Modern Clinical Syphilology*. Philadelphia: W. B. Saunders Company, 1934.

The specific cause of this infection is known, many of the properties of the etiologic agent have been determined, its modes of transmission are common knowledge, usable measures for an early diagnosis have been found, and therapeutic agents for quickly making an infected patient noncontagious are available. It would appear to be a simple matter to apply this knowledge, but this has not been done extensively. It is the responsibility of the medical profession to detect those persons with syphilis and administer the sterilizing and curative remedies. The general population has progressed in its sensibleness and desires to a standard which makes it possible to undertake a widespread campaign against syphilis. When the prevention of syphilis is approached objectively, positively and unrelentingly, the incidence of the disease will begin to decrease and finally will be eradicated. This is a worthy and desirable undertaking, probably the major health problem of the present day possible of accomplishment. It is true that a recent popular medical writer² sarcastically questioned the desirability of freeing the human race from syphilis, but few will agree with him.

SEROLOGIC SURVEYS OF POPULATION GROUPS

If the entire population through one generation should be repeatedly examined clinically and serologically for syphilis and every infected person

Present popular attitude toward routine serologic tests "You needn't test my blood. I know it is all right."

Desirable attitude "Everybody should have the blood tested at least every other year."

Groups in Whom Routine Serologic Tests for Syphilis Should and Can Be Performed

Hospital, clinic, office and home patients, physicians and nurses, dentists, servants, food handlers, soft drink dispensers, hotel employees, applicants for marriage certificates, applicants for automobile driving permits, applicants for insurance, students, public carrier employees, industrial employees, criminals, prostitutes, and others

Eventually the Whole Population

Slogans for popularizing routine serologic tests

promptly given the minimum standard of modern therapy, the malady could be eradicated. No such action is possible. The approach must necessarily be slower, but the present-day pace should and can be accelerated. Certain groups are now receiving routine examinations and many unsuspected cases are being discovered. This method of detection should become more widespread until eventually the entire population is covered.

Along with this mass examination, facilities for mass treatment must of course be made available. A few years ago the U. S. Public Health Service attempted to capitalize in a wholesale way the fact that anti-syphilitic treatment will render patients noninfectious. In selected areas it attempted mass sterilization of the Negro population based on extensive serologic surveys. The results and experiences were such that this method

of attack can be recommended. The example set by obstetricians, both in the success of teaching propaganda and in reducing the incidence of congenital syphilis, is another recommendation for the method of group serologic surveys.

TRACING SOURCE CASES AND CONTACTS

Another way of attacking this transmissible infection is by tracing source cases and the follow up of contacts of syphilitic patients. This is a direct epidemiologic

Chart 2—Result of case finding in a group of Negroes starting with a female patient with secondary syphilis

procedure and if pursued intensively and tactfully is effective. The principle of this approach is identical with that used in the control of other infectious diseases. The main difference is that sexual contacts are to be determined. Because of the tendency to secrecy the problem is somewhat difficult, but on the other hand the number of possible sources and contacts are limited, which simplifies the investigation.

It has been the policy at the University of Virginia Hospital³ for several years to investigate epidemiologically all early and familial cases of syphilis and any other cases that would seem to warrant scrutiny. This investigation is directed toward ascertaining the identity of the person from whom the patient acquired the disease and the identity of other persons exposed to the same source or to the patient following infection.

During the routine history and physical examination of the patient the fundamental characteristics of the disease are explained. This includes transmission, pathology, complications, standard of treatment, and the probable outcome. Language that the individual patient can comprehend is used. The moral aspects are minimized and the medical phases are emphasized.

Chart 3—In this group the husband infected the wife. Three of the four children were found to have acquired syphilis.

2 Zinsser, Hans. Rats, Lice and History. Boston: Little Brown and Company, 1935.

Every effort is made to impress the patient that all information obtained is confidential. With the proper build up, almost every patient will give the names and addresses of his sex partners and close associates. After obtaining this information the patient is asked to notify those concerned and advise them to be examined. In addition, a letter is sent to the contacts advising them to be examined. It is remarkable that almost all patients attempt to cooperate fully when

Recently it was reported by the Cooperative Clinical Group⁴ that 84 per cent of patients with early syphilis discontinue treatment before they are rendered permanently noninfectious. In our clinic 41.2 per cent of patients with early syphilis, observed during this period (1930-1934 inclusive) of intensive effort directed toward determining source cases and contacts returned for the minimum standard of treatment.⁶ This figure is exclusive of patients referred to other physicians or clinics. This was accomplished without the aid of social service or follow-up workers.

Improvement of this general condition is absolutely necessary if efforts to prevent syphilis are successful. The detection of syphilitic individuals, difficult as it is, is just the first step in the campaign. This 84 per cent of known foci of infection must be handled in some way, and the medical profession should work out an effective program. There are many details to be considered, such as education of the physicians, administrators of government and the general population, availability of diagnostic facilities, cost and availability of treatment, management of delinquent patients, and many others. Vonderlehr and his co-workers⁵ have outlined such a program, which can be recommended.

TABLE 1—Results of Serologic Survey for Syphilis in Negroes in Six Southern Counties*

| Number Examined | Number Positive | Early Cases† | Number Treated |
|-----------------|-----------------|--------------|----------------|
| 33,334 | 6,800 | 200‡ | 5,900 |

* Data obtained through courtesy of the U. S. Public Health Service.

† Period of greatest infectiousness.

‡ This figure would undoubtedly have been larger if it had been possible to determine the infections acquired within two years of the period when contagious relapse is most frequent.

TABLE 2—Follow Up and Follow Back of Early Syphilitic Infections and Contacts

| Infected Cases | | Exposed Contacts | | | | | |
|----------------|------------|----------------------|------------|----------------|------------|--------------------|------------|
| | | Admissions to Clinic | | | | Estimated Infected | |
| | | Total | | Cases Infected | | Total No. | Per Cent |
| Number | Percentage | Number | Percentage | Number | Percentage | Number | Percentage |
| 207 | 51.1 | 421 | 2.03 | 171 | 40.6 | 126 | 73.7 |
| | | | | | | 316 | 15.2 |

Nevertheless the first step in the prevention of syphilis is the detection of infected individuals, and the accompanying charts and tables illustrate something of the method of tracing source cases and contacts, the results and some ideas to be emphasized.

SUMMARY

Two practical epidemiologic methods of discovering syphilitic patients are (1) serologic surveys of population groups and (2) tracing source cases and contacts.

The physician with patience, tact and energy can markedly decrease the high percentage of patients with syphilis becoming delinquent before the completion of proper treatment.

Chart 4—Several groups of small episodes, one group showing heredo syphilis.

properly approached. The patient himself, in most cases, becomes to some extent a sanitary worker. Every case of syphilis diagnosed presents an opportunity for discovering other foci of infection.

This investigation probably cannot be done successfully by nurses or social workers alone. They, of course, can be of great aid in following up information obtained by the physician. The use of legal measures is sometimes necessary. It has been stated that this type of investigation would be less successful in a large city. On the contrary, rapid cheap transportation, more clinic facilities, social service departments and the like would seem to make it easier.

Chart 5—A large group centering about a small industrial plant employing young men and women. The plant was thirty miles from the clinic. The follow up was entirely by messages of patients and correspondence. Fifty even names of exposed persons were obtained; twenty-four per cent were examined in our clinic; nine gave negative examinations and fifteen were found to have acquired syphilis.

Other important results of this intimate relationship of patient and physician are the establishment of the patient's confidence in treatment and his education as to proper treatment. He is then more apt to continue treatment regularly, increasing his chance of cure and decreasing the possibility of an infectious relapse.

DEVELOPMENT OF ADEQUATE TREAT-
MENT FACILITIES FOR CON-
TROL OF SYPHILIS

JOSEPH EARLE MOORE, M.D.

BALTIMORE

In its relation to the public health, syphilis may aptly be regarded as two diseases, one of which, early syphilis, is infectious and, like tuberculosis and other infectious diseases, requires the attention of public health officers to diminish or prevent its spread, the other, late syphilis, is not a major problem because of infectiousness, but, like cancer, demands the attention of public health officers because of the high incidence of incapacitating disease and death which it causes.

The title assigned me tacitly assumes that treatment facilities at present available in the United States are not adequate for the control of syphilitic infection. In the discussion of this topic it is profitable to start with a definition of terms. What is meant, precisely, by the phrases "adequate treatment facilities" and "the control of syphilis"? As to the former, does "adequate" mean adequate to meet the present demand or adequate for the potential demand? As to the latter, it may perhaps be agreed that the control of syphilis means essentially the same thing as the control of smallpox or any other infectious disease, i. e., its virtual eradication.

A further assumption is involved in the title of this paper that if treatment facilities were adequate, the control of syphilis would be aided. This is perhaps more nearly fact than assumption. As to early syphilis, it is agreed that the spread of infection can be best prevented not by reformation of the sex morals of a nation or by the forcible isolation of infectious persons but by the early use of the arsphenamines. A single dose of one of these drugs provides a method of destroying surface organisms in a few hours, of healing infectious lesions in a few days, and of abolishing infectiousness with a rapidity not equaled by any method in any other infectious disease. It is, however, true that one or a few doses will not accomplish the permanent abolition of infectiousness, and that indeed to stop with one or a few doses may actually increase the incidence of infectious relapse over that to be expected if no treatment at all is given. To prevent fresh lesions from appearing, to reduce the incidence of infectious relapse to a minimum of 2 per cent or less, at least twenty injections of an arsphenamine plus an equivalent amount of heavy metal, given by the continuous system, are necessary.¹ From the public health standpoint, it seems obvious that, if it were possible promptly to recognize every individual freshly infected with syphilis and to administer this minimum of forty weeks of treatment, the spread of syphilitic infection would be immediately and enormously reduced.

As to late syphilis it is agreed that most forms of the disease are amenable to symptomatic relief and that progression or relapse may be prevented in the vast majority of cases if the proper form of treatment can be given over a long enough period of time.² It seems further obvious therefore, that if it were possible to

recognize all individuals with late syphilis and to administer the optimum amount of treatment, incapacity and death and the economic loss resulting therefrom could also be immediately and enormously reduced.

Whether early and late syphilis are being recognized to the maximum degree possible and whether, when recognized, they are being treated by proper methods and for the optimum length of time are points closely related to a discussion of treatment facilities adequate to meet the actual or potential demand. It is estimated by the United States Public Health Service³ that annually 1,140,000 persons with syphilis come under treatment for the first time since infection, of whom 518,000 have early and 596,000 late syphilis. This is an incidence rate of 8.4 per thousand of the population. Parenthetically, it may be noted that if the incidence rate of syphilis in this country were the same as in Denmark, we should have only 24,000 new cases annually instead of 1,100,000, or, conversely, if their rate were the same as ours, they would have had 32,000 new cases instead of their actual 700.⁴

Since, from the public health standpoint, we are more interested in early than in late cases, it is pertinent to ask: Do all patients with early syphilis seek medical attention competent to abolish infectiousness? If not, what proportion do seek such competent care and what happens to the remainder?

A definitive answer in exact terms cannot be given to these two questions, but such information as is available indicates that less than half the persons freshly infected with syphilis seek competent medical attention during the early and infectious stages of their illness. Two important reasons for this failure exist. First is the fact that early syphilis is sometimes, perhaps often, symptomless, i. e., the primary and secondary lesions are either completely lacking or so trivial and evanescent as to escape attention. How often this occurs in human beings is unknown and for various reasons is probably impossible of exact determination. There is reason to believe, however, that among syphilitic patients one man in every five and one woman in every three has acquired the disease without knowing it. Obviously, a patient who does not realize that he is ill does not consult a physician. Second, the American Social Hygiene Association has found that "annually more than twice as many individuals sought treatment for venereal disease across drug store counters as came to qualified medical sources in such cities as San Francisco, California, Birmingham, Alabama, Dallas, Texas, and New Orleans, Louisiana."

When casually asked what one should do if infected with a venereal disease, less than one half of the young men so questioned advised going to a clinic or to a medical practitioner for treatment, the remainder suggested some improper type of treatment, either self treatment or that obtainable from the (advertising quack or) "drug store, and in some instances advocated that no treatment be sought, stating that the lesion would heal of its own accord."⁵

It is fair to guess, therefore, that instead of a treatment demand from half a million freshly infected patients annually there should be, if all patients with early syphilis came at once to a recognized medical agency, a demand from at least twice as many, or a million annually.

From the Syphilis Division of the Medical Clinic of the Johns Hopkins Hospital.

Read before the Annual Conference of State and Territorial Health Officers with the Surgeon General of the U. S. Public Health Service, Washington, D. C., April 13, 1936.

⁴ Lombolt S. Rückgang der Syphilis in Danemark 1919-1933. Dermat. Wehnschr. 100: 173 (Feb. 9) 1935.

⁵ Parenthetical remarks mine.

What of patients with late syphilis? Why do so many patients delay applying for treatment until they have developed late syphilis? Is the annual crop of 600,000 such patients the maximum possible number who could be brought under treatment? The reasons for the delay in applying for treatment are given in the last paragraph—symptomless infection, treatment for early syphilis lacking because the disease was unrecognized, or inadequate because self administered or given by improper medical agencies. The actual demand for treatment of 600,000 new patients annually is far below the potential demand and is probably only a third of the number who might be brought under treatment if there were an organized effort to get them there, as I shall presently show.

The spontaneous demand on present treatment facilities is, according to the Public Health Service data, 1,100,000 new cases annually. The estimated potential demand, which can be readily realized by the application of the relatively simple method of case finding to be presently discussed, is between two and three times as great and for a few years at least could be pushed to 3,000,000 cases annually.

What of the present-day trend of the incidence of syphilitic infection in this country? Is it rising, falling or stationary? Data on this point are available in only a few communities—the state of Massachusetts,⁶ the state of Oregon, up-state New York,⁷ cities with populations of 100,000 or less, Cleveland, and six counties in the four states of Arkansas, Illinois, Kentucky and West Virginia.⁸ In some of these early syphilis is decreasing, in others increasing, over the six year period 1927-1933, resulting in a net decrease for the entire population studied of about 13 per cent. In nearly all these localities, however, the number of patients with late syphilis seeking treatment for the first time has increased, resulting in a net increase, for all stages of syphilitic infection, of 34 per cent. In view of the fact that a high percentage of patients fail to seek treatment until the late stages or remain untreated throughout life, Usilton concludes that the lower early syphilis rate cannot be interpreted as evidence of progress in the control of syphilis.

To the factors enumerated which operate to prevent persons infected with syphilis from seeking early and adequate medical care, i. e., symptomless infection, ignorance, carelessness, viciousness and the easy access to quack or drug store treatment, may be added one other factor, which applies to early and late syphilis alike, namely, the ignorance of many physicians of the elementary methods of recognizing syphilis. Unfamiliarity with the darkfield apparatus, a lack of understanding of the proper use or interpretation of serologic tests, an absence of appreciation of syphilis as an infectious disease—these are the blinders which hamper the medical profession.

When syphilis is recognized and brought under treatment how effective is the profession in keeping it there for the required time? The surveys of the United States Public Health Service⁹ show that at any one time 683,000 persons in this country are under treatment or observation for syphilis. Since 1,100,000 patients annually come under treatment for the first time and since the optimum average duration of treatment for early and late syphilis considered together is about two years, there should be under treatment at

any one time, under the present conditions of spontaneous demand, two and a quarter million persons. It is fair to say, therefore, that for the present case load, available facilities are a little better than 25 per cent efficient, and for the potential case load only about 10 per cent efficient. Reduced to their simplest elements the factors that contribute to this poor showing are (1) the ignorance or carelessness of the treated patient, (2) the ignorance or carelessness of the treating physician, (3) the inconvenience and relative inaccessibility of treatment and (4) the expense of treatment.

The remedies for these several defects in our modern diagnostic and treatment set up seem to me to fall into three main categories: case finding, education and an expansion and alteration of existing treatment facilities.

CASE FINDING

Organized case finding, a procedure familiar for years to public health officials and clinicians interested in tuberculosis, is apparently a relatively new idea in syphilis, or at least one that has received no general application. Yet there is available for the detection of syphilis a simple serologic test which is from 80 to 90 per cent efficient in any stage of the disease and far less expensive than the detailed physical examination, roentgenologic study and tuberculin testing so freely utilized in case finding in tuberculosis. Thirteen years ago I⁸ showed that in my own hospital about 5,000 syphilitic patients passed yearly through its inpatient and outpatient departments with the fact of their infection unrecognized because of failure to employ the serologic test for syphilis in every inpatient or outpatient admission. Only within the last six months has the procedure been adopted as a routine in every department of this one hospital, and, so far as I am aware, it is now one of only two large hospitals in the country with this regulation. Suppose this routine procedure were in force in all hospitals. In 1935 the United States had 6,246 hospitals with more than 7,700,000 total admissions to their beds alone,⁷ not including outpatient departments. If one admits the correctness of the estimate that 10 per cent of the American people are infected with syphilis (an estimate based on sound data) and if each one of these patients admitted to hospitals had had a serologic test for syphilis, some 770,000 syphilitic patients would have been recognized and brought under care.

The uncritical listener will at once reply that since the universal adoption of serologic testing among the occupants of hospital beds would have detected only 770,000 syphilitic patients, and since 1,100,000 were actually detected, we didn't do so badly after all. He loses sight of the fact that very few of the 1,100,000 actually recognized came from hospital beds, 95 per cent of them, if my own clinic is a fair sample, were ambulatory, not bed, patients. If the serologic test were routine in all outpatient as well as inpatient departments, and with the elimination of the possible duplication because some outpatients later become inpatients, at least another million syphilitic patients might have been recognized. Almost two million patients might have been detected in addition to the eleven hundred thousand who were recognized—a total of three million new syphilis patients annually!

To introduce the serologic test for syphilis as a routine in every department of all hospitals is perhaps an unobtainable counsel of perfection, yet it has been

⁶ Nelson, V. A. The Decreasing Prevalence of Syphilis in Massachusetts. J. A. M. A. 106:105 (Jan. 11) 1936.
⁷ Hospital Service in the United States. J. A. M. A. 106:783 (March 7) 1936.

⁸ Keidel, Albert and Moore, J. E. The Wassermann Reaction in the Johns Hopkins Hospital Bull. Johns Hopkins Hosp. 31:15 (Jan.) 1923.

nearly completely accomplished in one field of medicine, i. e., obstetrics, in which Exner⁹ reports that 93 per cent of 268 representative antepartum clinics examine every pregnant woman for syphilis by this method. If it is possible here, with the aim of eradication of congenital syphilis by the treatment of infected women, certainly it should be possible in other branches of medicine with the aim of prevention of infection of the woman.¹

To what extent would the spread of syphilis be reduced if this method of case finding could be employed universally in persons applying to hospitals for aid, to say nothing of those coming to physicians' offices? The cases recognized over and above those diagnosable clinically would be (1) those patients with early syphilis in whom the infection had been symptomless, or in whom the lesions had been unrecognized or misinterpreted by the examiner, (2) the large class of those with latent syphilis, i. e., with no clinical evidence of the disease, and (3) those with late syphilis whose lesions had been overlooked or misinterpreted. In our own syphilis clinic, these three classes make up 44 per cent of all admissions.

If case finding in syphilis by the method of routine serologic testing is to become an adopted procedure, it will become so by virtue of the efforts of the public health officer and by no other means. He is the person who can point out to hospital officials and private physicians the public health need and who can provide the laboratory facilities to make it economically possible.

With another important method of case finding the public health officer is even more directly concerned, namely, the epidemiologic investigation of contacts and families of infected persons. This method of approach, so familiar in other infections, is equally applicable to syphilis. Only by its use can one detect the ignorant, careless or vicious person who, though infected, escapes routine serologic testing because he does not consult any medical agency for advice.

Organized case finding by these two methods offers a solution of many of the difficulties encountered in getting patients under treatment. If they were generally applied, the demand for treatment facilities would be from two to three times greater than at present.

EDUCATION

Other speakers on this program are considering the importance of education in relation to syphilis control. In order to avoid infringement on their prerogatives, I must limit my remarks to the importance of education in bringing the infected patient under treatment and keeping him there as long as may be necessary.

The first requirement of the educational program is to educate ourselves. Case finding by the methods outlined will not entirely compensate for medical mistakes in diagnosis, especially of early syphilis. Physicians must be better trained in the principles and technic of treatment so that patients will not be prematurely dismissed from treatment or driven away by technical ineptitude.

So far as the lay public is concerned, the greatest factor in the control of cancer and tuberculosis has been the publicity these diseases have received. Press, magazines, placards, radio, all have made familiar the early symptoms emphasized the consequences of neglect and the necessity of reputable medical care,

and, as for tuberculosis, laid stress on the public health menace. Any adult who can hear or read has been repeatedly told, in brief but telling slogans, that "any lump in a woman's breast may be cancer", "don't spit, spitting spreads disease", "beware of the chronic cough, it may be tuberculosis", "consult your doctor at once if you have so and so". The people are, to use the advertising man's phrase, cancer and tuberculosis conscious.

The dissemination of similar knowledge concerning syphilis has, however, been left almost entirely in the hands of the advertising quack. His pamphlets, tossed surreptitiously into the parked automobile, mix misinformation about syphilis with encomiums of methods to promote waning sexual desire. Legitimate organized medicine and public health officials have done little or nothing to inform the public of syphilis, its prevalence, what it is, what its symptoms may be, how it infiltrates all levels of society, how it attacks innocent women and children, how and where it may be treated, what may be the consequences of neglect. Most laymen know none of these things. It is of course more difficult, because of the delicacy of the sex aspect of the subject, to popularize knowledge about syphilis than about tuberculosis and cancer. It may be necessary to avoid the slogan "A sore on the penis may be syphilis" and to replace it with the alternative "A sore anywhere on the body which refuses to heal may be syphilis. Consult your doctor." But if polite language can be found to tell elderly women that a bloody vaginal discharge may mean cancer, if advertisements concerning halitosis, body odors, feminine hygiene and sanitary napkins are complacently tolerated, surely words can be devised to inform the public about syphilis.

If the people have this information, more of them when infected will consult their doctors, and, of greater public health importance still, more of them will come early and will stay under treatment. An aroused and organized public opinion will aid in the elimination of the quack charlatan and cultist. Drug store treatment may be at least partially controlled by cooperation between public health officials and the pharmaceutical profession.

THE EXPANSION AND ALTERATION OF EXISTING TREATMENT FACILITIES

Facilities for the treatment of syphilis are provided by physicians in private practice, who care for perhaps 20 per cent of those under treatment, and by privately endowed charitable hospitals, municipalities and states. The latter agencies are responsible for the approximate 50 per cent of patients who can contribute nothing to the cost of their treatment and for the remaining 30 per cent who can pay something but not enough to finance private treatment. Detailed information as to the total number of free and part-pay clinics provided by all agencies, of the number of new patients admitted to them yearly, of the total number of visits, and of their success in keeping patients under treatment, is lacking. Since this is a conference of state and territorial health officers, it is perhaps worth while to refer very briefly to the contribution which these larger political units are making toward syphilis control. Information is available from forty-eight states and the District of Columbia.¹⁰

Reporting of venereal disease (including syphilis) is required by forty-six states. The system used is varied, and it is probable that in no state except Massa-

⁹ Exner M. J. Syphilis in Pregnancy. J. A. M. A. 106:438 (Feb. 8) 1936.

¹⁰ Vonderlehr R. A. Personal communication to the author.

chusetts is reporting even reasonably observed by physicians. The requirement of reporting by name or other identifying information not only interferes with compliance with the rule but is a distinct factor in driving patients away from reputable medical agencies into the hands of the quack, to the drug store or to self treatment. Lack of adequate reporting, and the further lack of adequate publicity to the public of the prevalence figures disclosed by such reports, is one cause of public apathy to syphilis and further hampers public health officials in determining the trend of infection. It is to be hoped that under the leadership of the United States Public Health Service a uniform and workable method of reporting may be developed for the entire country.

Forty-six states furnish free diagnostic laboratory service to physicians, which in most cases includes both darkfield and serologic tests. In few states, however, has there been developed a satisfactory consultation service, badly needed for such a complex diagnostic and treatment problem as syphilis. Arrangements should be made in each state for one or more consultation centers, to which patients might be referred by physicians or clinics for diagnostic opinion and treatment advice. These centers should provide specialists in various fields of medicine and expensive laboratory procedures, such as x-ray, otherwise not available.

Only twenty-two states operate or subsidize a total of 511 state controlled clinics for the treatment of syphilis. It hardly needs to be restated that, since these clinics, together with those provided by municipalities and privately endowed charity, are only 25 per cent efficient with the present case load, they will be even less adequate if and when the case load is doubled or tripled by case finding and informative publicity. More clinics are urgently needed. Whether these are provided by state, county or municipal funds or are established or enlarged in privately endowed institutions, the pressure bringing about expansion properly originates with public health officials. I am perhaps an incurable optimist, but I have the feeling that when the magnitude and importance of the syphilis problem is brought home to the lay public there will be a demand for the provision of adequate treatment facilities which the public health officer could not resist if he would.

Twenty-five states provide clinics and on request some or all practicing physicians with free drugs for the treatment of syphilis. This is of course a policy which should be carried out everywhere.

It is generally agreed that the most important factor contributing to the great decline of syphilis in Denmark, Sweden and Great Britain is the provision of free treatment for every infected person who desires it. This is the essential alteration of treatment facilities necessary in this country. It is unquestionably true that in this country many patients prematurely abandon treatment in so-called free clinics because of the constant demand for small fees at each visit. The specter of free treatment for all is one which need not alarm the medical profession, even in these days of heated discussion concerning socialized medicine. Years of familiarity with both clinic and private practice have taught me that the patient who can afford to pay for private treatment will not endure the inconvenience, loss of time from work, long waits, crowding, and possible publicity which attend clinic treatment. Private practice will lose nothing, but syphilis control will gain much, if the policy of free treatment is generally adopted.

There is an analogy between the attitude of public health officers toward the control of syphilis and other communicable diseases comparable to the attitude of the public toward war and peace, now uppermost in the minds of men. It is easy to arouse interest in war and in the acute infectious diseases. They are both dramatically sudden in their onset, dramatically starting in their manifestations, dramatically swift in their course. The measurable end result is victory or defeat, recovery or death. It is more difficult to arouse interest in syphilis and peace. There is nothing dramatic about a disease which drags on for twenty years or more, or about a state of public quietude that lasts forever. People are bored with both of them. But syphilis can be exciting enough to the person who has it, he wishes as ardently that he had never gotten it or that he were cured as does the nation plunged into war that it had been avoided or that it were safely over.

If there were in this country a million cases a year of smallpox, typhoid fever, poliomyelitis, plague, meningitis, Rocky Mountain spotted fever, or any one of a dozen other infections less serious than syphilis, there would be public health war indeed. The public health official would not require to be forced into action by popular panic. If panic over syphilis does not exist, it is in part because the people do not know the facts and in part because of the long drawn out course of the disease.

The more acute infectious diseases are focused in public consciousness by a series of "drives." What is needed for syphilis control is not a "drive," or a series, but sustained effort over many years. Primarily what is needed is an awakening of public health officials to the fact that 12,000,000 patients with syphilis in the United States constitute a challenge demanding the most intelligent thought and the utmost effort.

101 West Read Street.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary

B-K INHALATOR ACCEPTABLE

Manufacturer Bishinger-Koehler Manufacturing Co., Inc., Pittsburgh

This device consists of a mounting to which may be attached two cylinders each about 18 inches long, containing a mixture of oxygen and carbon dioxide under high pressure. Connected

B-K Inhalator

with the valves is a high pressure gage reading to 150 atmospheres, the purpose of which is to enable the operator to judge how much of the content of a cylinder has been used. The valves are so arranged that one cylinder may be held in reserve while the other is being used, and cylinders may be changed without discontinuance of the operation of the apparatus. From the valve system a small metal tube, capable of withstanding high pressure leads to an automatic valve which feeds the gas

mixture to the patient as it is used. This valve consists of a metallic bellows with sides of balloon fabric or similar material the tube and bottom of the bellows being connected together by a system of levers. The mixture of oxygen and carbon dioxide enters through a minute opening in the end of a tube the outer shape of which is conical. The lever system is so

arranged that pressure of oxygen opens this valve with difficulty from the cylinder side. Pressure of the gaseous mixture on the large area of the bellows closes the valve easily. It thus acts simultaneously as a reducing valve and as an automatic regulator of flow. From this valve a flexible metallic tube carries gas to a mouthpiece of celluloid (perhaps cellulose acetate) with an inflatable rubber edge of conventional type.

A relief valve is provided on the fitting that connects the flexible tubing with the mouthpiece. A valve on the bellows allows access of air in case the supply of oxygen should temporarily cease.

The whole is mounted in a substantial fiber trunk, inside which is a packet of tools and an instruction chart attached to the cover, giving directions for operation. Its combined weight is approximately 56 pounds.

This unit was examined in a clinic acceptable to the Council and was found to be well made mechanically.

The Council on Physical Therapy therefore voted to include the B-K Inhalator in its list of accepted apparatus.

HOLMSPRAY ATOMIZERS ACCEPTABLE

Manufacturer T J Holmes Company, Inc., Chartley, Mass.

The following atomizers were submitted to the Council for consideration.

Prescription Atomizer No 535—A nasal atomizer designed to spray aqueous oily and alcoholic solutions. Vacuum type construction.

Prescription Atomizer No 535—Designed to spray oily solutions. Volume of spray may be adjusted by a slight turn of the acorn shaped spray nozzle. Compression type construction.

Holmspray Throat and Nasal Atomizer,
No 600

Prescription Atomizer No 545—Leak proof designed for oily solutions. Adjustable spray feature. Compression type construction.

Nasal Atomizer No 575—Designed to spray aqueous alcoholic and oily solutions. The liquid tube of this atomizer may be removed for cleaning.

Throat and Nasal Atomizer No 585—Produces a fine fluffy spray suited for epinephrine solution.

Amber colored bottle with bent tube to take up last drop of solution. Volume of spray may be regulated by slight turn of the nozzle.

Throat and Nasal Atomizer No 600—Equipped with adjustable swivel tip. Sprays aqueous oily and alcoholic solutions. Swivel tip easily removed for cleaning purposes. Vacuum type construction.

Throat and Nasal Atomizer No 600 G—Same as Model 600 except that it is equipped with a removable glass liquid tube.

Atomizer No 602—Same as No 600 except that it is supplied with an extra amber colored bottle which makes it possible to distinguish between two solutions and to protect solutions sensitive to light.

Throat and Nasal Atomizer No 602-G—Same as 602, but has removable glass liquid tube.

Nonspil Throat and Nasal Atomizer No 612—Designed to handle all forms of sprays aqueous oily alcoholic, and silver solutions. Equipped with glass liquid tube and an adjustable spray regulator. Air tight clog proof and leak proof features which guard against deterioration and make it possible to carry atomizer without spilling.

Nonspil Nasal Atomizer No 611—Nasal atomizer having same features as No 612. Air tight clog proof and leak proof.

In view of the satisfactory results obtained with these units, the Council on Physical Therapy voted to include the Holmspray Atomizers in its list of accepted apparatus.

CORRECTION

Burdick Suction-Pressure

Unit—In the report of acceptance for the Burdick Suction-Pressure Unit (THE JOURNAL, August 1, p 354), inadvertently the wrong illustration was published. The accompanying illustration is the proper one. Furthermore the last sentence in paragraph three, reading "Pressures between —80 and —20 mm. of mercury may be obtained," should read "Pressures between +80 and —120 mm. of mercury may be obtained."

Burdick Suction-Pressure Unit

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

ANAEROBIC ANTITOXIN (See New and Nonofficial Remedies, 1936, p 360)

Lederle Laboratories, Inc., Pearl River, N Y

Tetanus Gas-Gangrene Antitoxin Globulin Lederle Modified—A polyvalent antitoxin prepared by the method of refinement against the toxins of *Bacillus tetani* (Cl tet) (Cl perfringens) and *Vibrio septique* (Cl. oxinis are individually prepared in suitable " aerobically after inoculation with anaerobically grown cultures. Some horses are immunized with injections of but one toxin, while others are immunized against several simultaneously. When trial bleeding tests indicate that horses have achieved a suitable antitoxic potency aseptic bleedings of plasma are made. This product differs from tetanus-gas-gangrene antitoxin refined and concentrated Lederle chiefly in the method of refinement. According to the manufacturer, the process of refinement is based essentially on a controlled method of selective digestion of the proteins of the immune horse blood with pepsin. As a result of this process, up to 90 per cent of the coagulable protein may be digested, a small portion is precipitated and the remainder a pseudoglobulin fraction is purified first by ordinary filtration and then by ultrafiltration and dialysis. The resultant solution is sterilized and standardized the same as antitoxin solutions obtained by the usual salting out methods. Tests for the content of tetanus antitoxin perfringens antitoxin and *Vibrio septique* antitoxin are made according to the methods described by the National Institute of Health. The product is marketed in packages of one syringe containing one prophylactic dose and one vial containing one prophylactic dose, stated to represent tetanus antitoxin 1500 units perfringens antitoxin 2000 units and *Vibrio septique* 2000 units.

Dosage—Prophylactic the contents of one syringe or vial within twelve hours of the injury. If there is still further danger of infection this may be repeated in five to seven days.

Gas Gangrene Antitoxin (Polyvalent) without Tetanus Antitoxin Globulin Lederle Modified—A polyvalent antitoxin prepared by immunizing horses against the toxins of *B perfringens* (Cl perfringens) *Vibrio septique* (Cl oedematis maligni) *B oedematis* (Cl oedematis), *B sordelli* (Cl sordelli) and *B histolyticus* (Cl histolyticum). The toxins are individually prepared in suitable broth mediums grown aerobically after inoculation with anaerobically grown cultures. Some horses are immunized with injections of but one toxin while others are immunized against several simultaneously. When a potent antitoxic serum (as indicated by potency tests applied to trial bleedings) is obtained aseptic bleedings of plasma are made. This product differs from gas-gangrene antitoxin (polyvalent) without tetanus antitoxin Lederle chiefly in the method of refinement. The process of refinement is based essentially on a controlled method of selective digestion of the proteins of the immune horse blood with pepsin as a result of this process, up to 90 per cent of the coagulable protein may be digested, a smaller portion is precipitated and the remainder a pseudoglobulin fraction is purified first by ordinary filtration and then by ultrafiltration and dialysis. The resultant solution is sterilized and standardized the same as antitoxin solutions obtained by the usual salting out methods. Tests for the content of perfringens antitoxin and *Vibrio septique* antitoxin are made according to the method prescribed by the National Institute of Health. *B oedematis* (Cl oedematis) antitoxin is tested according to the method prescribed by the Commission of Biological Standardization of the League of Nations in August 1934. The *B histolyticus* (Cl histolyticum) and *B sordelli* (Cl sordelli) antitoxins are tested for potency by injection into mice of serial dilutions of the antitoxin with definite amounts of the respective toxins the M. L. D. of the toxins having previously been determined on mice. The unit of *B histolyticus* (Cl histolyticum) is defined as that amount which will neutralize 100 M. L. D. of *B histolyticus* (Cl histolyticum) toxin for a 20 Gm mouse. The unit of *B sordelli* (Cl sordelli) antitoxin is defined as that amount which will neutralize 1000 M. L. D. of *B sordelli* (Cl sordelli) toxin for a 20 Gm mouse. The product is marketed in packages of one vial containing one therapeutic dose stated to represent perfringens antitoxin 10000 units *Vibrio septique* antitoxin 10000 units *oedematis* (Novyi) antitoxin 200 units and *sordelli* antitoxin 200 units.

Dosage—Therapeutic for tetanus and gas gangrene, an initial intravenous injection of one to four minimum therapeutic doses supplementary injections may be given in from four to six hours or as soon as they are indicated by the symptoms.

ANAEROBIC ANTITOXIN (See New and Nonofficial Remedies 1936, p 360)

Mulford Biological Laboratories, Sharp & Dohme, Inc., Philadelphia and Baltimore

Tetanus Gas Gangrene Antitoxin Mixed Mulford—An antitoxic serum prepared by immunizing horses with gradually increasing doses of the toxins of Cl tetani (B tetani) Cl Welchii (B perfringens) and Cl oedematis-maligni (*Vibrio septique*). After the desired degree of potency is obtained, the horses are bled the plasma is separated and the serum is prepared in a manner similar to that used for other antitoxic serums. Marketed in packages of one ampule vial and one syringe containing 1500 units Clostridium tetani antitoxin 2000 units Clostridium Welchii antitoxin and 2000 units Clostridium oedematis-maligni antitoxin.

Dosage—For prophylaxis the contents of one syringe or ampule injected subcutaneously in a single dose. To maintain the antitoxic titer of the blood the dose is repeated on the third or fifth day.

BRINGING SYPHILIS INTO THE LIGHT

For centuries public discussion of syphilis has been submerged largely because of esthetic considerations. Recently this policy of suppression has itself attracted notice because broadcasting companies have preferred to keep the word "syphilis" and the subject "off the air." Great indignation has been expressed in public health circles. Nevertheless newspapers and magazines have been equally reticent to make any mention of syphilis except under the circumlocution of "a social disease." The great majority of men and women who have mentioned the subject at all have spoken of it as "a blood disease" or, among the less cultured, as "a bad disease."

Physicians are accustomed to face disease frankly and to a great extent have divorced the so-called venereal diseases in their thinking from social and moral questions. The real trouble goes beyond the radio and the press, which no doubt reflect the attitude of the average adult. The average man and woman still shrink from the knowledge that syphilis is a leading cause of deaths which are usually attributed to heart disease, diseases of the nervous system and other chronic diseases.

Several metropolitan newspapers, cited by Pinney¹ in a recent contribution, have not only opened their editorial and news columns and even their headlines to the mention of the word syphilis but have definitely enlisted their influence against the disease through series of featured articles. Parran² has said that the conquest of syphilis may be the next great step in progress against endemic pestilence. In this battle the part played by the medical profession is of the utmost importance. The best weapon against syphilis is the prompt, adequate and persistent treatment of the acute case and of the syphilitic pregnant woman. This is the function of the physician. The public health official must do his part by searching out the foci of infection. Syphilis has been shown to be a disease the endemic

character of which is expressed largely through groups of limited epidemics frequently traceable to one or at the most a few infected persons. Between the discovery program of the health officials and treatment by physicians, the conquest of syphilis is an imminent possibility. In this conquest the natural cooperation that ought to exist between the medical profession and public health agencies will be demanded to the fullest extent.

MILK NOT POTENT FOR CEVITAMIC ACID

Recent studies of the vitamin C in cow's milk have suggested that this food may actually be a significant source of the antiscorbutic factor,¹ hence it is interesting to inquire how much milk would have to be ingested to supply the total human needs for cevitamic acid. Göthlin² has estimated that for a 60 Kg man from 19 to 27 mg of crystalline cevitamic acid constitutes the minimum protective dose (from 0.31 to 0.45 mg per kilogram). More recently Everson and Daniels³ have made an exact quantitative study of the vitamin C retentions of three preschool children with intakes up to 7.5 mg per kilogram of body weight, retentions of the antiscorbutic vitamin paralleled ingestions, whereas excess quantities up to 12 mg had no significant influence on the amount retained. The largest quantity, over 4 mg per kilogram, was retained by the youngest child, suggesting that young tissues may need more of this factor than those only slightly older. If maximum retention is an exact criterion of the requirements of an organism for cevitanic acid, a total intake for such children would necessitate between 113 and 143 mg daily. No direct study of the needs of infants is yet available, but by indirect means an approximation can be made. A curative dose of natural or synthetic cevitanic acid of from 30 to 50 mg daily for infants with acute scurvy has been used successfully in many cases and a prophylactic dose of 10 mg has been suggested.⁴ By an examination of the amounts of vitamin C reported in human milk,⁵ the size of a protective dose for infants may be estimated, for breast-fed infants do not develop scurvy even in its latent form.⁶ Neuweiler⁵ has asserted that human milk furnishes an average of from 4 to 7 mg of cevitanic acid per hundred cubic centimeters, five or six times the amount in the cow's milk used for reference, and one-tenth the quantity in lemon

juice, while Selleg and King³ have reported an average of from 5.5 to 8 mg per hundred cubic centimeters during the first few weeks of lactation, thus supplying to the nursing infant from 40 to 50 mg of cevitic acid daily. Either the needs of the infant are less than those of the preschool child, or protection of the infant against scurvy may be assured on quantities less than the amounts needed for maximum retention in the preschool child.

If milk were to serve as the sole source of vitamin C and if, as used by the consumer, it contained as much of this factor as Whitnah and Riddell found (25.9 mg per liter), a 60 Kg man would need to consume for optimal protection considerably more than a liter daily, a preschool child would be obliged to drink over 4 liters daily for maximum retention of cevitic acid, and a nursing infant would need almost 2 liters of cow's milk of the potency described to obtain the same quantity of vitamin C as its mother's milk would have furnished.

Though it has been shown that fresh and even pasteurized milk can now be secured having a content of cevitic acid larger than formerly, such milk cannot be considered a rich source of the antiscorbutic factor. This food does therefore contribute cevitic acid to the diet but, because of a probable reduction in potency under ordinary home and hospital conditions, cow's milk should not be depended on to supply the entire human needs for vitamin C.

BEJEL—NONVENEREAL SYPHILIS

From the clinic of the American Mission at Deir-ez-Zor, Syria, comes a series of contributions by Hudson and his collaborators¹ on a form of syphilis, known as "bejel," found among the Arabs of the middle Euphrates valley. The evidence for believing that bejel is a purely nonvenereal form of syphilitic infection lies along four lines: (1) The Bedouin villagers are prevented from sexual promiscuity by geographic, economic and social barriers, (2) the Bedouins, large numbers of whom have been treated in the clinic, are free from venereal lesions and diseases, (3) the Bedouins say that there is no promiscuity among them and attribute the widespread propagation of bejel in their communities to infection through innocent contact, usually in childhood, and (4) experience with the clinical course of bejel confirms the fact that it is a nonvenereal community disease of the Bedouins acquired during childhood.

The population studied is distributed for the most part along the middle Euphrates River, its tributary the Khabur River, and a semiarid region known as the Syrian desert. The people are insulated from contacts

with the outside world to a remarkable degree. The settled population of the region numbers about 200,000, of which 195,000 are indigenous Moslem Arabs. The Christian population numbers about 5,000 and has little social significance. The Moslems can be divided into townsmen, constituting about 50,000 of the group, and the Bedouins, of whom about 132,000 live in small mud villages along the banks of the Euphrates River and 13,000 live similarly along the Khabur River. The Moslem Arabs have long given syphilis two names, depending on the source of the infection. In the towns the contraction of syphilis through venereal contact is referred to as *franghi* (the disease of the Franks, or foreigners), whereas childhood infection among the townspeople is given the Bedouin name of *bejel*. The Bedouins, however, refer only to *bejel*, which has the connotation of a childhood exanthem and carries with it no sense of venereal exposure.

In reviewing the records of 8,000 consecutive new admissions to the clinic, data for the statistical study of 2,617 patients were obtained. These fathers and mothers were distributed in three social groups, about 500 being Christians, 1,000 townspeople and 1,000 Bedouins. They were married adults of all ages, but most were within the childbearing decades. The average ages of the three groups showed no material variation. Consideration of the positive serologic reactions, darkfield examinations, histories and clinical observations led to the conclusion that the incidence of syphilis in the Bedouins was 90 per cent, in the townspeople 35 per cent, and in the adult Christian population between 10 and 12 per cent. In spite of this there was no marked difference between the three groups in the average number of pregnancies or percentage of living children born. In fact, the incidence of miscarriage was definitely lower among the Bedouins than among the other two groups, which in turn were about equal in this respect. The evidence for the nonvenereal nature of bejel rests also on its apparent epidemiology. Recognizable primary lesions, such as are found in the venereal form, are practically never seen in the Bedouins. However, the Bedouin method of supplying drinking water for the family offers opportunity for the transfer of spirochetes and probably determines the usual site of the earliest lesions. A child with bejel does not usually show much constitutional change, and the children are reputed never to die of bejel. The active lesions on the mucous membrane of the oral cavity swarm with spirochetes having all the characteristics of *Spirochaeta pallida*. Furthermore, the patronage of prostitution and the incidence of gonorrhea lend further corroboration to the acceptance of bejel as a nonvenereal disease. Among the Christians the patronage of prostitution exists to a degree closely comparable to that in the West and exists to some degree among the townspeople. The primitive Bedouin, however, has a highly developed sense of sexual propriety which the closely knit clan life of the community

Reaction to the Presumptive Kahn Test in Patients with Bejel (Nonvenereal Syphilis). *Arch. Path.* 21: 727 (June) 1936.

still preserves. The statistics for gonorrhea were even more conclusive. Of the ninety-eight patients with gonorrhea seen among the 7,000 new patients admitted to the clinic, fifty-five were Christians, forty-one were townsmen and only two were Bedouins. The records of the clinic do not show any Bedouin women with gonorrhea or with any of the sequelae of gonorrhea.

The question of the congenital transmission of bejel was of course closely studied. It was believed that children are usually born free of the disease for several reasons. The classic picture of congenital syphilis is rarely seen in Bedouin infants. There is a definite contagious element in bejel, babies and young children do not present manifestations of the disease until they have been handled and fondled by older children who have open lesions. Bedouin children lack such important manifestations of the congenital disease as interstitial keratitis, hutchinsonian teeth and eighth nerve deafness. Children who have "not yet" had bejel have a negative Kahn reaction. Finally, it was not infrequently necessary to treat a father or mother who contracted bejel from their children. It seems probable, therefore, that syphilis in this form is rarely transmitted prenatally or congenitally and that when propagated under epidemiologic conditions similar to yaws is no more likely than that disease to affect the second generation.

The extensive studies of venereal and nonvenereal syphilis existing side by side in an exceedingly large percentage of the population indicate graphically the still incomplete knowledge of the syphilis problem. It would be especially interesting to know by what route and in what form syphilis reached this isolated community.

Current Comment

THE PHARMACOPEIA AND THE PHYSICIAN

The new Pharmacopeia, the eleventh revision, became official in June 1936. The preparations included in the Pharmacopeia for use in the diagnosis or treatment of diseases were selected by the Subcommittee on Scope, which included many prominent physicians. In order that doctors may have easily available a reference to the products included in the Pharmacopeia and also to their manner of use, a special series of articles has been prepared suggesting the ways in which these medicines may be prescribed in the treatment of disease. The series of articles, which begins in this issue of THE JOURNAL, has been developed through cooperation by the Committee of Revision and the Board of Trustees of the Pharmacopeia with THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. In order that the suggestions may be as useful as possible, the writers of the articles have not been restricted to the use of official medicines if in their judgment other therapeutic agents seem to be more useful. It is proposed to publish these articles at frequent intervals until the

entire series is completed, at which time the articles will be assembled in book form and be made generally available at as low a price as possible. The purpose of this series is to encourage the use of Pharmacopeial and other well established remedies rather than the use of unestablished and unwarranted proprietary preparations.

OSTEOPATHY IN ENGLAND

Last year, after an extensive investigation of osteopathy with a view to official recognition in Great Britain, those who were seeking official recognition voluntarily withdrew their application. The withdrawal followed an extensive presentation of their case with an equally adequate presentation by those who sought to show the unscientific character of osteopathic manipulation. The hearings were fully reviewed in the columns of THE JOURNAL during their progress. However, osteopathy and the associated cults are not idle in promoting their claims. Almost any citizen who secures the limelight, from applicants for the presidency to those in lesser positions, is said sooner or later to be a regular adherent of osteopathic practice and to submit himself and his family at regular intervals to osteopathic adjustments. In most instances these claims are not justified. A few weeks ago a periodical called *News Week* indicated that the new king of England had also selected an osteopath and that Sir Morton Smart, a well known orthopedic surgeon, had been selected for the position. Quite promptly thereafter Sir Morton Smart received the following letter from Oakley Smith, president and founder of the Chicago School of Naprapathy.

Honorable Sir —

Ever since a blind Osteopath—a graduate of the first class of the British College of Osteopathy—paid us the honor of visiting our classes here in America, I have had a rather unusual interest in the strides of Osteopathy in England.

In this week's issue of "NEWS-WEEK" I have read the following:

"Before leaving for France, the King created two new posts. He made his personal pilot, Lt. Edward (Mouse) Fielden, Captain of the King's Flight.

Sir Morton Smart, osteopath to lesser Britons, became Manipulative Surgeon to His Majesty."

If you feel like it I should be very happy to have a line from you concerning the accuracy of this item and indicating if you still feel like it, something of the duties which will fall upon you because of your high post.

Sincerely,

OAKLEY SMITH, D.N.

The letter disturbed Sir Morton Smart considerably. He calls attention to the following statement, which has been published under his own signature in British newspapers:

I have consistently pointed out ever since osteopaths came to this country from America that the pathology of osteopathy as set out by osteopaths is without any scientific basis and is totally opposed to the pathology of manipulative surgery. If the osteopathic conception were founded on scientific reasoning and supported by scientific evidence it would be necessary in the interests of the community completely to reorganise the medical education in every country in the world.

Incidentally, Oakley Smith is not even an osteopath. The naprapaths would certainly not assert that disease was due primarily to pressure of bones of the spine.

on nerves coming out between the bones. They feel, instead, that disease is caused by the actions of ligaments which pull the bones of the spine on to the nerves. "You pay your money and you take your choice."

Medical Economics

MEDICAL SERVICE FOR COLLEGE STUDENTS

Approximately 1,000,000 persons, aged from 17 to 24, attend the institutions of higher education in the United States for from four to six or more years. During that period a large percentage of these students receive medical care and instruction in hygiene under a specialized form of organization—the student health service. About 90,000 students who go out from the colleges of this country every year will be leaders in society and will be expected to exemplify their health training as well as their mental education. These graduates constitute one of the most influential groups which the medical profession can reach.

In the interest of establishing some fundamental principles that might be accepted and applied in the correct provision of medical care to this section of the population, the Board of Trustees requested that a study be made of student health services in all leading colleges in the United States. The conclusions of the report¹ are as follows:

1. There has been, during the last decade, a steady increase in the number of institutions maintaining student health services. The trend in the student health movement is definitely toward a single department for the administration of the continuously expanding personal medical services and health activities.

2. Conclusions pertaining to the financial advantages or disadvantages of an organization of medical services for students are rendered dubious by the inadequacy and inaccuracy of the financial records for student health services. The reported cost per student is not appreciably less than the cost for similar services in the private purchase of medical and hospital care.

3. There appears to be a surprisingly large amount of capital invested in buildings and equipment devoted to health and medical services for students. A few health services have shown that student medical care plans can be operated effectively and economically without large investments in buildings and equipment by utilizing the medical agencies and facilities of the community.

4. There seems to be a general tendency to develop health and medical services in colleges and universities on an institutional rather than a geographic basis. The extension of student health services into comprehensive medical care plans disrupts the professional practice of medicine into a system of institutional medical enterprises. Under such plans the patient is considered as a member of a restricted cultural group rather than as a human being subject to his entire environment.

5. There is a growing belief that the place of the student health service in the community medical scheme should be that of an agency to supervise the health of students and to teach health standards but in all instances to use the community's health resources in a manner approved by the medical profession.

6. Neither the organization nor the conduct of student health services appears to have followed any generally accepted principles or objectives except to provide students with some sort of health instruction and variable forms and degrees of medical advice and care. The essential pedagogic and medical factors in the health program seem to have suffered because new activities were adopted by student health services without careful investigation of their usefulness and largely to advance athletics.

7. There seems to be evidence to show that the health education of students, which is presumably the primary function of a student health service, has not always been so effective as might be expected of institutions of higher learning. The health education program, which should enable college students to acquire health principles and hygiene practices that will influence public opinion and social custom for the betterment of human health, has been neglected because of unnecessary emphasis on the treatment and management of illness among the students.

8. A universally accepted measure of performance or accomplishment by which the programs and benefits of student health services may be judged has not been evolved. The lack of a proper method of appraisal has permitted a confusion of clinical and health educational activities to the detriment of the more widely beneficial education program. The evaluation of student health services may be made possible by properly prepared health records and health tests.

9. It appears that a large percentage of universities and colleges are actually engaged in the practice of medicine in varying degrees. The successful operation of a few student medical care plans in accordance with the ethical principles of the medical profession indicates that there are no insurmountable obstacles to operating other similar student health services.

10. The segregation of a section of the medical profession by student health services under standards built on a compromise between the ideals of medicine and the interests of educational institutions is proving harmful to the medical profession and to the educational institutions alike. The division within the medical profession reduces its influence in molding the standards and ethics of student medical care plans into a form that will best serve the prevention and cure of disease.

11. The number of instances in which a practical cooperative arrangement has been effected between the college and the county medical society of the college community for the medical care of students seems to be lamentably small. It does not appear likely that the health education objectives of a student health service will be achieved until student health services harmoniously cooperate with the medical profession.

The possibilities of these student medical care-plans for good or for bad in the medical field are far reaching and the course they take will depend on how much leadership the medical profession assumes. To this end it is important that each county medical society in every community where there is an institution of higher education should have an active committee devoted to a study of the problems of student health services. This committee should be in close and continuous contact with the administrators of the educational institution to keep all medical subjects in accordance with professional standards. Furthermore, wherever it is possible to secure the cooperation of school administrators, the county medical society should have complete control of all the strictly medical activities necessary to satisfy the needs of the educational institution and its students. From the entrance physical examination to the major surgical procedure, all medical relationships with each student should be performed in agreement with ethical practices as stipulated by the medical society. The method or form of organization to accomplish this cooperation can be arranged by the local institution and the local medical society.

The Expert and the Pseudo-Expert —Years ago Lawson Brown said that the specialist could be distinguished from the general practitioner by the fact that the specialist when he examined the lungs made the patient cough, the general practitioner did not! For the past quarter-century the graduates of every first-class medical school in the United States have been taught the importance of this maneuver. Today the true expert is distinguished, first by an abiding faith in inspection, palpation, percussion and auscultation and second, by a strong conviction that the roentgenogram is best interpreted in the light of clinical impressions. The pseudo-expert is recognized, on the one hand, by his contempt for the stethoscope, a contempt which varies directly with his ineptitude in its use and, on the other hand, by a childlike faith in his own clinical deductions from the roentgenogram.—Waring, J. J. *The Vicissitudes of Auscultation*, *Am Rev Tuberc* 34:1 (July) 1936.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

Personal—Dr. Hubert R. Owen, Wedowee, has been appointed health officer for Winston County—Dr. Frank M. Hall, formerly of Leeds, has been appointed health officer of Limestone County—Dr. Martie F. Parker, Boaz, has been made health officer of Monroe County, with headquarters in Monroeville.

Society News—The Northwestern division of the Alabama State Medical Association and the Fayette County Medical Society met in Fayette, July 9, with the following speakers, among others: Drs. James M. Mason, Birmingham, "Diverticulitis of the Ileum," Carl A. Grote, Huntsville, "Present Status of Tuberculosis," and Thompson F. Wickliffe, Jasper, on otomycosis.

Prevalence of Infantile Paralysis—From January 1 to August 28, 314 cases of infantile paralysis with twenty-five deaths have been reported to the state department of health. In concentration of cases, Jefferson County led with twenty-three cases reported since the first of August. Lauderdale is second with thirteen during this period and Cullman third with ten cases. Four cases each were reported in Lawrence and Blount counties, while Colbert reported three. Sporadic cases appeared in the following counties: Franklin, Madison, Morgan, Marshall, Tallapoosa, Mobile and Marengo, two cases each, and one each in Marion, Winston, Etowah, Calhoun, Elmore, Montgomery, Pike, Baldwin, Chilton and Limestone.

Deaths from Accidents Increase—Accidental and violent deaths were the fifth leading cause of death in Alabama in 1935 with a rate of 63 per hundred thousand of population. In 1933 this classification was seventh and in 1934 sixth in the list of causes of death. Home accidents caused 613 deaths, industrial 192, motor vehicles 599 and other public accidents 341. Of the home accidents 28.2 per cent were caused by falls, 29 per cent by burns. One hundred and seventy of these were deaths of children under 5 years of age and 184 of persons 65 or over. Among the children under 5, 29.4 per cent of the deaths were from burns, 28.2 from asphyxiation and 13.5 per cent from poisoning. Among the older group, 63 per cent of the deaths were from falls, 20.6 per cent from burns.

ARIZONA

Personal—Dr. Bernice L. Steward, Coolidge, has been appointed physician to the state penitentiary in Florence, succeeding his brother, the late Dr. Hobart B. Steward.

Campaign of Tuberculosis Prevention—The state health department with the cooperation of the U. S. Children's Bureau, the Arizona departments of the Forty and Eight and the American Legion, has begun a statewide campaign of tuberculosis prevention. The work will be entirely diagnostic and will be under the direction of Dr. Willis D. Gilmore, recently of Tombstone, who has joined the state board of health as tuberculosis consultant.

CALIFORNIA

Society News—Dr. Eugene S. Kilgore, San Francisco, addressed the Sonoma County Medical Society, August 13, in Santa Rosa, on heart diseases—Drs. Edwin I. Bartlett and Howard H. Markel, San Francisco, addressed the Humboldt County Medical Society, Eureka, August 6, on bone tumors.

CONNECTICUT

The New State Medical Journal—The first issue of the *Journal of the Connecticut State Medical Society* made its appearance in August. It will be published quarterly for this year according to present plans. Dr. Stanley B. Weld, Hartford, is editor.

Annual Clinical Congress of State Society—The Connecticut State Medical Society will hold its annual clinical congress in New Haven, September 22-24. The speakers will include:

Dr. Frederic W. Bancroft, New York, Our Duty to the Fracture Patient
Dr. Burrill B. Crohn, New York, Etiology, Treatment and End Results of Gastrointestinal Ulcer

Dr. Foster Kennedy, New York, What the General Practitioner Should Know About Neurology
Dr. Thomas M. Rivers, New York, Poliomyelitis
Dr. Louis G. Herrmann, Cincinnati, Recent Advances in the Diagnosis and Treatment of Peripheral Vascular Diseases
Dr. Vilny P. Blair, St. Louis, Injuries of the Bones and Soft Tissues of the Face
Dr. Warren T. Vanghan, Richmond, Recent Advances in the Study of Food Allergy
Dr. Walter T. Dannreuther, New York, Clinical Manifestations of Ectopic Gestation
Dr. Leonard Greenburg, Albany, N. Y., The Practicing Physician and the Diagnosis and Treatment of Occupational Diseases
Dr. Edwin H. Place, Boston, Salient Experiences in Thirty Years with Contagious Diseases

In addition, there will be symposiums on treatment of fractures, peptic ulcer, neurology, poliomyelitis, peripheral vascular disease, injuries to the bones and soft tissues of the face, food allergy, gynecology, industrial diseases, immunity procedures in acute infections, and endocrinology. Bedside clinics at the New Haven Hospital will also form a part of the program.

DISTRICT OF COLUMBIA

The Annual Refresher Courses—Georgetown University School of Medicine will conduct the first of a series of annual refresher courses, September 14-19. Sessions will be held at the medical school and the Georgetown University, Children's, Gallinger Municipal and Episcopal Eye, Ear and Throat hospitals. The course, which will cover the specialties, is given to acquaint graduates of the medical school with the newer developments in medicine and surgery and the allied branches. It will be concluded with a dinner Saturday evening September 19.

GEORGIA

Society News—Dr. Olin S. Cofer, Atlanta, addressed the Fulton County Medical Society, Atlanta, August 20, on "Treatment of Cholecystitis"—Dr. Alton M. Johnson, Valdosta, addressed the Coffee County Medical Society, Douglas, August 25, on "Pylorospasm in Infancy"—Dr. James R. Paulk, Moultrie, addressed a meeting of the South Georgia Medical Society, July 14, at the home of Dr. William W. Turner Jr., Nashville, on the use of the bronchoscope—Speakers at a meeting of the Fourth District Medical Society in Warm Springs, August 10, were Drs. Wilmer Baker, New Orleans, on "Handling of Accidents Occurring During the Administration of Anesthesia", Arthur Neal Owens, New Orleans, "Principles of Plastic Surgery", Launcelot Minor Blackford, Atlanta, "Cardiac Pain," and Frank K. Boland, Atlanta, "Immediate Care of Fractures."

ILLINOIS

Personal—Dr. Charles H. P. G. Benning, district health officer of Royal Oak, Mich., has been named school health director of Peoria.

Deaths from Diabetes Increase—The state health department reports that diabetes is now a hazard twice as great as that of tuberculosis for the population in one half of the cities and in one third of the counties of Illinois. Deaths from diabetes have more than tripled during the last twenty-five years, the report stated, while those from tuberculosis have been cut in half. Last year, diabetes caused nearly twice as many deaths as did tuberculosis in twenty-five principal cities and thirty-four counties of the state. There were 1,978 deaths attributed to diabetes in Illinois last year against 600 in 1910 and 342 in 1902, the health department reported.

Society News—Drs. William B. Serbin and Laurence E. Hines, Chicago, addressed the McHenry County Medical Society, August 26, on "Pathology and Treatment of Proctodentia of the Uterus and Present Knowledge of Endocardial Infections" respectively—Dr. Lee O. Frech, Decatur, addressed the Randolph County Medical Society, August 27, on medical economics—Dr. Ford K. Hick, Chicago, will address the Bureau County Medical Society, September 8, on pneumonia—At a meeting of the Lee County Medical Society, September 7, Dr. Howard L. Beye, Iowa City, will speak on management of acute conditions in the abdomen—Dr. Lowell D. Snorf, Chicago, will present a paper before the Union County Medical Society, September 10, on "Diagnosis Pathology and Advancements in the Treatment of Duodenal and Gastric Ulcers"—The Macoupin County Medical Society was addressed July 28 in Carlinville by Drs. Frederick O. Schwartz and Martin F. Kouri, both of St. Louis, on "Eye Conditions Treated by General Practitioners" and "Medicine in School Organization" respectively.

Chicago

Personal—Dr Maximilian J Hubeny has been appointed chief of the x-ray department of Cook County Hospital, succeeding Dr Chester H Warfield, who has held the position for eight years

INDIANA

Dental Demonstration—The bureau of maternal and child health of the Indiana State Medical Association and the Indiana State Dental Association have begun a joint dental program. A trailer containing full dental equipment has been acquired, and Janesville has been selected as the first town for the service. Greene and Owen counties have been designated the first to receive this service because statistical studies of the number of persons on relief, the average industrial income, agricultural income and the general financial status of the two counties show their need. Dental services will be limited to children between 3 and 10 years of age, and only those referred by local agencies and dentists in the county in which the mobile unit is located, and whose financial status has been determined will be accepted. Robert L. Peden, DDS, will operate the mobile unit under the direction of Mary H. Westfall, DDS, Indianapolis, who will continue to direct the dental educational program of the state for the coming year. The services of the unit will be limited to prophylaxis, cement and amalgam fillings, and extraction.

IOWA

Promotions at State University—Dr Horace M. Korn has been promoted to be professor of the theory and practice of medicine at the State University College of Medicine, it is announced. Other changes on the medical faculty include:

Walter R. Ingram, Ph.D., assistant professor of neuro-anatomy
Dr Placidus J. Liefelder, assistant professor of ophthalmology
Dr Jacob J. Potter, assistant professor of otolaryngology
Wald W. Tuttle, Ph.D., associate professor of physiology

Diphtheria Prevention Program—During June the state department of health instituted a program of diphtheria prevention in seventeen counties in cooperation with local medical societies. Social security funds were used to pay physicians in these counties for giving one dose of diphtheria alum precipitated toxoid to all resident children between the ages of 9 and 24 months. The treatments were administered in the offices of the participating physicians. Each county medical society set the amount to be charged the parents for giving the treatment to children over 24 months of age. An analysis of the records of diphtheria prevention programs conducted prior to June 1 shows that only 28 per cent of all the children treated were in the age group 5 years and under. Under the new plan, 71 per cent of all the children treated were of preschool age. Since more than 60 per cent of the deaths from diphtheria in Iowa occur in this group, the new plan offers greater possibility for reducing mortality, the state journal points out. The participating counties in the recent program were Adams, Appanoose, Dallas, Davis, Decatur, Keokuk, Louisa, Lyon, Madison, Mills, Monona, Monroe, Page, Polk, Poweshiek, Ringgold and Shelby. With federal funds available for the remainder of the fiscal year ending June 30, 1937, the new project will be launched in Audubon, Buchanan, Cass, Crawford, Delaware, Dubuque (exclusive of the city of Dubuque), Harrison, Jackson, Marion, Pottawattamie (exclusive of the city of Council Bluffs), Winnebago and Woodbury (exclusive of Sioux City) counties.

KENTUCKY

Personal—Dr Addie M. Lyon, Frankfort, has been appointed health officer of Lawrence County.—Dr Lee A. Dare Ashland, has been appointed health officer of Anderson County to succeed the late Dr Squire R. Boggess, Lawrenceburg.—Dr James L. Vallandigham Lexington, has been appointed superintendent of the Eastern State Hospital, Lexington.

LOUISIANA

Educational Campaign in Tuberculosis—The Tuberculosis and Public Health Association of New Orleans will carry on a health education campaign in the city schools in the fall under the auspices of the woman's auxiliary of the Orleans Parish Medical Society.

Superintendent of Charity Hospital Resigns—Dr Arthur Vidrine, since 1928 superintendent of Charity Hospital, New Orleans, has resigned to devote full time to his duties as

dean of Louisiana State University Medical Center. He has been succeeded by Dr George S. Bel, New Orleans, chairman of the board of administrators of the hospital, it is reported.

Society News—Dr Morris Fishbein, Chicago, editor of THE JOURNAL, will give an address before the Orleans Parish Medical Society, October 2, on "The New and Changing Social Order in Medicine".—Drs Ralph E. King, Winnsboro, and James B. Vaughan, Monroe, among others, addressed the Franklin Parish Medical Society in Winnsboro recently on "Injection Treatment of Hernia" and "Hemoglobinuria" respectively.—Dr Melville W. Hunter Monroe, addressed the Tri-Parish Medical Society in Tallulah August 4 on "Pain in the Chest, with Special Reference to Heart Conditions".

MARYLAND

Typhoid and Floods—The state department of health reports that for the first six months of 1936 only fifty-three cases of typhoid were recorded in spite of the menace of the disease following the destructive floods of March and April. This total compares with 85 in 1935, 124 in 1934, 113 in 1933 and 143 in 1932. Of the fifty-three cases, seventeen occurred in Baltimore and thirty-six in the counties of the state. Carroll, Cecil, Howard, Prince George's, Queen Anne's and Somerset counties reported no typhoid during the first six months of this year.

New Occupational Disease Bureau—The Baltimore City Department of Health has established a new bureau of occupational diseases. Dr John M. McDonald, Baltimore, has been placed in charge. The newly created department will assist in a survey now being conducted for the Maryland Commission for the Study of Occupational Diseases to determine the probable incidence of industrial disease in the state. Cooperating in the study are the state department of health, the state commissioner of labor and statistics, and the Baltimore department of health.

MICHIGAN

Graduate Courses—The department of postgraduate medicine, University of Michigan, Ann Arbor, and the Michigan State Medical Society are cooperating in a series of graduate courses, beginning the first week in October and continuing eight weeks. The courses will be given in the following centers: Grand Rapids, Battle Creek and Kalamazoo jointly, Lansing and Jackson jointly, Cadillac and Manistee jointly, Flint, Bay City and Traverse City. A composite of the course will be given in October in Marquette, Houghton or Escanaba, according to the state medical journal. Some of the subjects to be considered include allergic diseases, malposition of the uterus, common psychoneuroses in adults and children, recognition and management of acute and chronic diseases of the ear, care of the injured person, including the recognition and emergency care of fractures, and ulcerative lesions of the gastro-intestinal tract.

MISSOURI

Dr McCordock Succeeds Dr Loeb—Dr Howard A. McCordock, associate professor of pathology, Washington University School of Medicine, St. Louis, has been appointed head of the department to succeed Dr Leo Loeb, whose retirement was recently announced. Dr McCordock was born in Brooklyn in 1895 and graduated from the University of Buffalo School of Medicine in 1923. He has been at Washington University since 1929.

MONTANA

State Medical Election—Dr William P. Smith, Columbus, was chosen president-elect of the Medical Association of Montana at the annual meeting in July. Dr John A. Evert, Glendive, was installed as president and Dr Elmer G. Balsam, Billings, was reelected secretary. Next year's meeting will be in Great Falls in July.

NEBRASKA

Clinical Assembly at Omaha—The fourth annual assembly presented by the Omaha Mid-West Clinical Society will be at the Hotel Paxton, October 26-30. Guest speakers will be Drs Joseph C. Beck, Loyal Davis and Morris Fishbein, editor of THE JOURNAL, Chicago, Hugh Cabot and George B. Eusterman, Rochester, Minn., Alan Brown, Toronto, John Shelton Horsley, Richmond, Elliott P. Joslin, Boston, James R. McCord, Atlanta, Bernard P. Widman, Philadelphia, Philip D. Wilson and Fred Wise, New York. Clinics will be held October 30 at St. Joseph's and University of Nebraska hospitals.

NEW JERSEY

Officers of Medical Board—Dr Arcangelo Liva, Rutherford, was elected president of the state board of medical examiners, July 22, Dr James J. McGuire, Trenton, secretary, and R. M. Colborn, D. O., Newark, treasurer.

Typhoid Traced to Spring Water—Thirteen cases of typhoid were reported in Englewood August 24. Ten of the thirteen patients had drunk from a spring in the town, samples from which showed presumptive evidence of contamination.

NEW YORK

Society News—Dr Harvey B. Matthews, Brooklyn, addressed the Suffolk County Medical Society, Bellport, July 22, on "Breech Presentation."—The annual conference of secretaries of county medical societies will be held in Albany, September 15.

University News—Dr Edward W. Koch, dean of the University of Buffalo School of Medicine, has been made dean also of the dental school. Dr Elmer Heath, assistant professor of medicine, has been made assistant dean of the medical school and Russell W. Groh, D.D.S., professor of operative dentistry, assistant dean of the dental school. Dr Koch is a graduate of Rush Medical College, Chicago, and has been on the faculty at Buffalo since 1918, when he was appointed professor of pharmacology. He has been dean of the medical school since 1930.

New York City

Personal—Dr Aaron Arnold Karan Wallum Lake, R. I., has been appointed assistant director of the Jewish Hospital of Brooklyn. The hospital recently established a serum center with Dr Sidney D. Kramer in charge.—Dr Howard Lilienthal recently exhibited three oil paintings and a pastel at the Wayside Arts Gallery on the Albany Post Road, Garrison-on-Hudson.

Dr Elsberg Honored—The medical staff of the New York Neurological Institute honored Dr Charles A. Elsberg, chief of surgical service, at a tea on his sixty-fifth birthday, August 24. A special volume of the *Bulletin* of the institute, containing forty original articles contributed by Dr Elsberg's colleagues and students, was presented to him. Informal addresses were made by Drs J. Bentley Squier, Frederick Tilney, Cassius H. Watson, Leo M. Davidoff and Dudley D. Roberts.

Mental Hygiene Clinic at Kings County Hospital—More than 500 patients were treated at the mental hygiene clinic at the Kings County Hospital in the first four months of its existence, the department of hospitals reported in July. Cases have been referred from the board of education, the department of public welfare, the board of child welfare, the crime prevention bureau and the department of health, from other city hospitals and other medical institutions, from private citizens and from the courts. A similar clinic is needed at Queens General Hospital, the department stated, and an organization committee has been appointed to plan it.

The "Transparent Woman"—The New York Museum of Science and Industry placed on exhibition August 19 the *Camp "Transparent Woman"*. Dr Dean D. Lewis, Baltimore, unveiled the exhibit and Roy Chapman Andrews, director of the Museum of Natural History, was a speaker at the ceremony. The "Transparent Woman" like the "Transparent Man," which was exhibited at the Century of Progress in Chicago in 1933 and is now on permanent exhibit at the Mayo Clinic, Rochester, Minn., was made at the Museum of Hygiene, Dresden. After a period at the museum the exhibit will be sent on a trans-continental tour, which is expected to last more than two years.

City Hospitals Overcrowded—During the first six months of 1936, city hospitals were filled to 97.4 per cent of their capacity and seven were greatly overtaxed, the department of hospitals recently reported. The seven and their ratio of occupancy to normal capacity were: Queensboro, 126.3 per cent, Fordham 115.1, Riverside 114.3, Sea View, 112.9, Bellevue 106.5, Kings County 103.4 and Lincoln, 100.2. The statistics showed that 130,111 ward patients were admitted compared with 125,891 for the corresponding period of 1935; the average hospital stay was 22.4 and dispensary visits totaled 1,296,918. The death rate was 8.3 compared with 8.2 for the preceding year. Dr Sigismund S. Goldwater, commissioner of hospitals, directed attention to the fact that although Manhattan has numerous private hospitals an exceptionally large proportion of the population is found in public hospitals. Manhattan with 23.5 per cent of the population of New York supplies 44.5 per cent of the patients in the city hospitals while Brooklyn with 37.2 per cent of the population supplies less than 20 per cent

of the indigent sick. In a recent hospital census it was found that in Manhattan there was one patient in a municipal institution for each 220 of the borough population, for the Bronx one out of 666, for Brooklyn one out of 526, for Queens one out of 770 and for Richmond one out of 666. Kings County Hospital is now the city's largest single hospital unit, with 2,885 beds. Bellevue has 2,313.

Changes in the Faculty at Columbia—Dr Charles A. Flood has been appointed assistant dean of the College of Physicians and Surgeons of Columbia University to succeed Dr Frederick T. van Beuren Jr., who resigned. Dr Flood graduated from the college in 1928 and joined the staff in 1934 as assistant in medicine and director of the student health service. Promotion of Dr Virginia K. Frantz to be assistant professor of surgery and Dr David Seegal to be assistant professor of medicine was also announced. Appointments in recent months include those of Dr Samuel A. Cosgrove, Jersey City, N. J., as clinical professor of obstetrics and Dr Phillips Thygeson, Iowa City, as assistant professor of ophthalmology. Recent promotions include:

Dr Samuel T. Orton, professor of neurology
Dr James Burns Amberson Jr., professor of clinical medicine
Dr George E. Daniels, professor of clinical psychiatry
Dr Martin H. Dawson, associate professor of medicine
Dr John H. Dunnington, associate professor of ophthalmology
Dr Harold T. Hyman, associate professor of pharmacology
Dr Claus W. Jungblut, professor of bacteriology
Dr Robert L. Levy, professor of clinical medicine
Dr Alvan L. Barach, assistant professor of clinical medicine
Rhoda W. Benham, Ph.D., assistant professor of dermatology
Dr Richard M. Brickner, assistant professor of neurology
Dr Thomas K. Davis, clinical professor of neurology
Dr Paul Gross, assistant professor of dermatology
Dr Halford Hallock, assistant professor of orthopedic surgery
Dr Hubert S. Howe, clinical professor of neurology
Dr George H. Hyslop, assistant clinical professor of neurology
Dr Thomas H. Johnson, assistant professor of ophthalmology
Dr Leonidas Lantoumias, assistant professor of orthopedic surgery
Dr Charles A. McKendree, clinical professor of neurology
Dr Irving H. Pardee, clinical professor of neurology
Dr Lewis B. Robinson, assistant professor of dermatology
Dr Leon A. Salmon, assistant clinical professor of neurology

OHIO

British Physiologist to Address Cleveland Academy—Sir Joseph Barcroft, professor of physiology, Cambridge University, England, will open the fall season of the Cleveland Academy of Medicine with an address September 24 on "The Genesis of Respiration." Sir Joseph was a member of the expedition to the Chilean Andes to study physiology of high altitudes several years ago and has recently engaged in research on the fetal circulation.

Gift to Medical Library—The Cleveland Medical Library Association has received recently a bequest of about \$7,000 through the will of Mrs. Ida Marvel Ford, to be known as the Cozad-Ford Homestead Collection on Malignant Tumors, to commemorate families who owned and occupied the land on which the library is located. The income from this bequest is to be used to establish and maintain a library on malignant tumors, to foster library research or to provide for public lectures on the subject.

Rabies in Columbus—Strict quarantine on dogs has been imposed by the health commissioner of Columbus. Dr Nelson C. Dysart, in an effort to prevent rabies. In less than one month more than 100 persons had been bitten by dogs many were taking antirabic treatment and fifteen dogs heads had been found positive for rabies according to *Ohio Health News*. It is now unlawful for any dog to be at large except in the enclosed yard of its owner and dogs on the street licensed or unlicensed must be on leash accompanied by a responsible person. In the last ten years there have been forty-seven deaths from rabies in Ohio, it was reported.

OREGON

Personal—Dr Ralph A. Fenton, Portland, has been appointed a member of the board of regents of Reed College, Portland.

Society News—The Eastern Oregon Medical Society held its annual meeting in LaGrande in June with the following speakers: Drs. Laurence Selling, Frank E. Butler, Plair Holcomb, Raymond E. Watkins, Adalbert G. Bettman and Thomas M. Joyce, all of Portland; Grover C. Bellingier, Salem; and George W. Swift, Seattle. Dr. Chas. O. Wainwright, Peoria, Ill., was elected president.

PENNSYLVANIA

Society News—Drs Lucian D Johnson and Stuart D Scott addressed the Fayette County Medical Society at Connelville September 3 on "Arrhythmias of the Heart" and "Common Infections of the Nasopharynx" respectively

Philadelphia

University News—The late Dr Charles Harrison Frazier, professor of surgery at the University of Pennsylvania School of Medicine, bequeathed to the university a large part of his medical library

Hospital News—Mount Sinai Hospital has announced a series of health talks for the public to be delivered monthly during the coming winter by members of the hospital staff. The first will be given September 23 on "Common Disorders of the Stomach." Other subjects to be discussed are syphilis, high blood pressure, teeth, hay fever, diabetes and cancer

Pittsburgh

Personal—Dr John P Griffith associate professor of surgery, University of Pittsburgh School of Medicine, has been appointed professor to succeed Dr John J Buchanan, who is now professor emeritus.—Dr Jennings C Litzenberg, Minneapolis, addressed the Pittsburgh Obstetrical and Gynecological Society at its annual meeting recently on "Fallacies of Ectopic Pregnancies"

RHODE ISLAND

New Health Units—The state department of health has established three new district health units in cooperation with the U S Public Health Service, according to the *Rhode Island Medical Journal*. The personnel of each unit will include a physician as director, a sanitary inspector, one or more public health nurses and a clerk technician. Dr James P O'Brien, Woonsocket, will be in charge of the north district. Dr Joseph Castronovo, Providence, the southeast district, and Dr Raymond F McAteer Peacedale, the south district. Until now Providence and Warwick have been the only communities in the state with full time health service

TENNESSEE

New Health Unit—A district health unit including the counties of Fentress, Pickett, Clay, Putnam and Jackson was opened the first week in August with headquarters at Livingston. Dr Harold M Kelso, Gallatin, formerly health officer of Sumner County, is in charge of the new unit

Health at Memphis—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended August 22, indicate that the highest mortality rate (21.6) appeared for Memphis and that the rate for the group of cities was 10.3. The mortality rate for Memphis for the corresponding week of 1935 was 15 and that for the group of cities 9.9. The annual rate for the eighty-six cities for the thirty-four weeks of 1936 was 12.6 as against a rate of 11.7 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area outside the city limits or that it has a large Negro population may tend to increase the death rate

TEXAS

Twenty-Five Years of Teaching—Dr Clarence M Grigsby, professor of clinical medicine, Baylor University College of Medicine, Dallas, was guest of honor at a dinner celebrating his completion of twenty-five years as an instructor in the school. The dinner was given by Dr Walter H Moursund, dean of the college, at the Nurses' Home of Baylor Hospital. The faculty presented to Dr Grigsby a portrait of himself

WASHINGTON

Society News—At a meeting of the Klickitat County Medical Society at White Salmon in June speakers were Drs Arthur C Jones, Portland, Ore., on physical therapy, Robert D Wiswall, Vancouver, industrial medicine and state medical legislation and De Walt Payne, The Dalles, Ore., diseases of the ear, nose and throat

Health Department Furnishes Antisyphilitic Drugs—The Washington State Department of Health is now furnishing to physicians arsenicals to render patients with syphilis non-infectious. When a local health officer receives a report of a case of syphilis he refers it to the state department, which immediately sends three tubes of the drugs to begin treatment. The object of this policy, according to *Northwest Medicine*

is to place syphilitic patients under treatment as quickly as possible and to cultivate in physicians the habit of reporting cases to health officials

Railway Surgeons' Meeting—The annual session of the Great Northern Railway Surgeons' Association will be held at the Olympic Hotel, Seattle, September 25-26. The scientific program will be presented Friday morning, September 25, with the annual golf tournament in the afternoon at the Seattle Club and the banquet in the evening at the Rainer Club. A fracture clinic will be presented Saturday morning, September 26, at the Providence Hospital under the direction of Dr Howard J Knott. In the afternoon members will attend the Minnesota-Washington football game

WISCONSIN

First County Health Unit Established—Marathon County established August 1 the first county health unit in Wisconsin, one of three model units to be set up in the state with the aid of state and federal funds. Dr Harold H Fechtner, Wausau, has been appointed health officer. The federal government appropriated \$5,800, the state \$1,000 and the county \$3,400

Society News—The Central Wisconsin Society of Ophthalmology and Otolaryngology met in Appleton June 7-8. Speakers were Drs Harry Gradle, Chicago, on "Uveitis" and "Modern Surgical Treatment for Detachment of the Retina", William A Kennedy, St Paul, "Allergic Manifestations in the Eye, Nose and Throat," and Fred S Cook, Eau Claire, "Foreign Bodies in the Esophagus and Bronchi"

PUERTO RICO

Society News—At the first scientific meeting of the Puerto Rico chapter of the Pan American Medical Association in San Juan, July 11, speakers were Drs Jose Rodriguez Pastor, San Juan, on "Organization of Health Insurance for the Poor", Rafael Lopez Nussa, Ponce, "Surgical Treatment of Elephantiasis", Ramon M Suarez, "Study of the Bone Marrow in Chronic Schistosomiasis Mansonii", Isaac F González Martínez, Roentgenotherapy in Cancer of the Base of the Tongue, Pharynx and Larynx, and Manuel Díaz-García, "Physiology and Logical Treatment of Hand Infections".—Dr Eric M Matsner, executive secretary of the National Medical Council on Birth Control, New York, addressed the Puerto Rican Medical Association, September 1, in San Juan, on "Medical Aspects of Contraception"

GENERAL

Society News—The annual conference of the National Society for the Prevention of Blindness will be held in Columbus, Ohio, December 3-5.—The fourteenth Congress of French-Speaking Physicians of North America will be held in Montreal, September 7-10

Rural Health Service in the United States—The U S Public Health Service reports that 612 counties in thirty-eight states now have whole time county township or district health service as of Dec 31, 1935, an increase of seventy-one units over 1934. The greatest gains were in New Mexico, in which whole-time service was established in twenty-five counties and in Virginia, where twenty-three counties established the service. According to the report, 28.7 per cent of the rural population of the country now has whole-time health service. Delaware, Maryland and New Mexico lead among the states in this respect, all counties in these states being provided with whole time health service. Of the 612 units 587, or 95.3 per cent were receiving financial assistance from one or more of the following agencies: the state board of health, the U S Public Health Service, the Rockefeller Foundation, the American Red Cross, the American Women's Hospital Fund, the Rosenwald Fund, the Commonwealth Fund and the Milbank Fund

Fraudulent Instrument Repair Man—A Missouri physician reports that a man using the name J C Hartley recently visited him soliciting orders for instruments and for replating old ones. The man said he represented his own firm of Hartley and Company in St Louis. He victimized four physicians in one town and has not been heard from since. Letters sent to the St. Louis address have not been delivered. The man was described as being about 5 feet 8 inches tall, weighing about 140 pounds, slightly stooped, with dark hair, thin in front, dark complexion, smooth shaven and wearing glasses. He is said to have shown an excellent knowledge of instruments, their uses and value. An account of similar impositions on physicians appeared in *THE JOURNAL*, June 6, page 2015

Deaths from Diabetic Coma—In 1935, 18 per cent of the deaths of diabetic policyholders of the Metropolitan Life Insurance Company were attributed to primary diabetic coma, according to the *Statistical Bulletin*. Of the ninety-seven diabetic children in the study, 70 per cent died from coma, which is four times the proportion occurring at the older ages. Coma was responsible for more than 16 per cent of the deaths at ages 20 and over. In this group it was found that only 28 per cent actually were reported to have used insulin. In emphasizing the need for insulin treatment in this class of patients, the bulletin points out that the incidence of coma deaths among regular users of insulin was one-third lower than that in the entire group. Many coma patients in the study were not known to be diabetic until their final illness. The proportion of coma deaths among them was twice that among patients in whom the disease was diagnosed earlier. This, it was stated, points clearly to two important facts: the value of early diagnosis and the necessity for care in distinguishing diabetic coma from coma resulting from other causes.

Bequests and Donations—The following bequests and donations have recently been announced:

Pennsylvania Hospital Philadelphia \$40,000 for study of gastrointestinal diseases from the estate of Justice M. Thompson after the death of his widow.

Lancaster General Hospital Lancaster Pa. \$69,000 by the will of Alfred B. Grubb half to be reserved for a niece during her lifetime. Lawrence and Memorial Associated Hospitals, New London Conn. \$400,000 by the will of Miss Virginia Palmer.

Mount Sinai Hospital New York, as subsidiary legatee, will receive \$92,369 under the will of the late Edward J. King.

Mount Sinai and Montefiore hospitals, New York, \$50,000 and \$25,000 each from the estate of Stella Hædelberg Abrahamson for the Ahmanson Neurological Funds.

R. I., \$80,000 from the will of the late Mrs. N.

Western Reserve University School of Medicine Cleveland, \$1,000 as a gift from Mrs. Ida Zangerle Krause in memory of her late husband Dr. Carl R. Krause to be used for the benefit of needy students.

United Hospital Inc., Port Chester N. Y. \$5,000 under the will of the late Harry De Berkley Parsons.

The Solomon and Betty Loeb Convalescent Home Eastview N. Y. \$500,000 from the will of the late James Loeb.

Columbia University New York \$50,000 to establish the Tucker Fellowship in obstetrics by the will of Mrs. Georgianna Tucker.

St. Luke's Hospital, New York \$8,886 by the will of Jane Noyes Smith.

Beth Israel Hospital Newark, N. J. \$2,000 for two ward beds by the late Dr. Jacob Polcavski, Newark.

Presbyterian Hospital New York, \$5,000 by the will of the late James Wilson.

Beth Israel, Mount Sinai and Montefiore hospitals New York, \$1,000 each in the will of the late Samuel J. Sonderling.

Brooklyn Hospital Brooklyn N. Y. \$10,000 by the will of Sophia D. Doshier.

CANADA

Society News—At the annual meeting of the Ontario Neuro-Psychiatric Association at the Ontario Hospital, Brockville, in June, speakers included Dr. Charles H. McCuaig and Dr. Trevor Owen, Toronto, on "Difficulties in Differentiating Between Hyperthyroidism and Anxiety States," and Dr. Daniel Plouffe, Montreal, Quebec, on "Attitude of the Psychiatrists as Experts in Criminal Courts." Dr. George H. Stevenson, London, was elected president.

Canadian Association Election—Starr Medal Awarded.—Dr. Theodore H. Legget, Ottawa, was named president-elect of the Canadian Medical Association at the annual meeting in Vancouver June 22 and Dr. Herman M. Robertson, Victoria, was installed as president. The Frederick Newton Gisborne Starr Medal was awarded to Sir Frederick Banting and Dr. Charles H. Best of the University of Toronto Faculty of Medicine, Toronto, and Dr. James B. Collip, McGill University Faculty of Medicine, Montreal, for preeminent services to the cause of medicine in Canada. The Starr medal was established in 1935 by the widow of the late Dr. Starr, who was for several years general secretary of the association and president in 1927. He died in April 1934.

Summer School in Vancouver—The fourteenth annual summer school of the Vancouver Medical Association will be held in Vancouver at the Hotel Vancouver, September 8-11. Following are the guest instructors and their subjects:

Dr. Irvine McQuarrie Minneapolis edema, basic minerals, role of fats and fatlike substances in health and disease, convulsive disorders of childhood.

Dr. Everts A. Graham St. Louis thoracic surgery, gallbladder disease, surgery of the pancreas.

Dr. Rollin T. Woodruff Chicago diabetic coma, diabetes with surgical complications, insulin, protamine, treatment of nephritis.

Dr. Gordon B. New Rochester Minn. malignant diseases of the mouth and accessory structures, tumors of the neck and larynx, reconstructive surgery of the face.

Dr. John McF. Berland Baltimore accidental and direct complications, relief of pain, puerperal infections.

Dr. Clarence B. Farrar Toronto evolution of a delusion, psychoneurosis and psychotherapy, differentiation of benign and malignant symptoms in incipient mental disorders.

Dr. Claude E. Dolman Vancouver undulant fever.

FOREIGN

Congresses Postponed—The tenth conference of the International Union Against Tuberculosis, scheduled for September 7-10 in Lisbon, Portugal, has been indefinitely postponed, according to the *New York Sun*, August 18. The fourth International Congress of Pediatrics, which was to have been held this year in Rome, has been postponed to April 1937, according to *Science*.

Personal—Dr. Edward Mellanby, secretary of the Medical Research Council, Sheffield, England, received the Moxon gold medal from the Royal College of Physicians of London, July 30, in recognition of his work on problems of nutrition.—Bernard E. Read, Ph.D., head of the physiologic division of the Henry Lester Institute for Medical Research, Shanghai, China, recently received the King Medal of the Peiping Society of Natural History for his contributions to "further knowledge in the field of natural sciences, especially in this instance for his meritorious work on Chinese drugs."—The Charles Graham Medical Research Fund of the University of London recently awarded a gold medal to Sir Thomas Lewis, London, in recognition of his work on treatment of heart disease.—Dr. Hugh B. Matland, professor of bacteriology and director of the department of bacteriology and preventive medicine, University of Manchester Faculty of Medicine, has been appointed dean of the school to succeed Prof. Henry S. Raper, according to the *Medical Press and Circular*.

Deaths in Other Countries

Julius Tandler, for many years professor of anatomy at the University of Vienna and for ten years minister of health in Austria, died in Moscow in August, aged 62, according to an Associated Press dispatch from Vienna in the *New York Times*, August 27.

Government Services

Changes in Public Health Service

The appointments of the following physicians as assistant surgeons in the regular corps of the U. S. Public Health Service have been announced: Howard D. Fishburn, San Francisco; Theodore L. Perrin, Boston; and James G. Telfer, Miami, Fla. The following transfers in the service have also been reported:

Passed Asst. Surg. Harold D. Lyman relieved at Washington D. C., and assigned to marine hospital San Francisco.

Passed Asst. Surg. Alfred J. Aselmeyer, relieved at Boston and assigned to Washington D. C.

Asst. Surg. Thomas T. Tomlinson Jr. relieved at New Orleans and assigned to National Institute of Health Washington.

Recent promotions in the service include Drs. Warren F. Draper and Lewis R. Thompson to medical director in the regular corps, Drs. John D. Reichard, Vance B. Murray and Thomas H. D. Griffiths, to senior surgeon in the regular corps.

Veterans' Administration to Build More Hospitals

The Veterans' Administration recently announced the approval by President Roosevelt of the acquisition of ground for two new hospitals, the leasing of a third, and the construction of additions to two existing hospitals. Accordingly, the administration will accept a site to be donated by Henry Ford comprising about thirty-seven acres in Dearborn, Mich. A twenty-five bed treatment station to cost not in excess of \$100,000 will be built in Reno, Nev., on a site known as Recreation Park donated by the city of Reno. The institution to be leased is Wisconsin Memorial Hospital in Mendota, which comprises seventeen buildings on 130 acres of land. This hospital will now accommodate about 300 beds and on completion of a small clinical building which will be undertaken by the state authorities the administration will be able to expedite hospitalization of beneficiaries in that area. A new administration building will be constructed at Newington Conn., including such replacements or remodeling as are necessary at a cost not to exceed \$80,000. At the facility at Hot Springs S. D., a new hospital building of fifty-eight beds with a surgical suite will be constructed and existing buildings will be rearranged to provide forty-two additional beds at a cost not to exceed \$170,000.

The Public Health

In the house of commons the minister of health, Sir Kingsley Wood said that the estimates for his department amounted to \$105,000,000, an increase of \$6,000,000 over those of 1935. The increase arose mainly from increased provision for housing, improvement of rural water supplies and health insurance. No country was making such provision for its social services. During the present year the expenditure on all such services, including the amount raised by local rates, would reach the considerable figure of \$2,100,000,000 and that 30,000,000 men, women and children would benefit from one or more such services. There had recently been great expansion in public works. Last year the total amount of works sanctioned rose from \$130,000,000 to \$180,000,000, a figure that had been exceeded only twice since the war. These works included large sums for hospitals, improved drainage, street lighting, public baths and open spaces and waterworks. Better sanitation and better housing and the efforts for improvement in the prevention, diagnosis and treatment of disease, and especially the diffusion of knowledge in principles of health, had borne fruit.

THE IMPROVEMENT IN THE HEALTH OF THE NATION

The latest figures showed that the death rate for 1935 was 11.7 per thousand of population. The expectation of life at birth had increased by seven years in the last twenty years. The infant mortality was 57, which compared well with so recent a year as 1929, when the rate was 74. At last maternal mortality showed a slight decrease as compared with previous years. The significance of the decline in the death rate could be better appreciated if it was analyzed in terms of persons living in each age group. Of persons living in each quinquennium from 5 to 45 years the numbers who died were less than half what they were fifty years ago. In the first quinquennium of life the number was less than a third of the number fifty years ago. Last year the principal infectious diseases showed no disquieting features. Influenza aroused no anxiety. There was entire freedom from smallpox. Unlike scarlet fever, diphtheria had not shown any progressive loss of virulence, but antitoxin given early had saved many young lives and it was now possible by artificial immunization in the preschool age to reduce considerably the danger of infection in the most susceptible years of life. Typhoid had fallen step by step with improved water supply and better sewerage and disposal of refuse. But infectious diseases were still responsible for over 60 per cent of all deaths in the ages from 1 to 15 years, although there had been a remarkable decline in the mortality. Death rates at ages under 15 per million living had declined for measles from 750 in 1910 to 201 in 1933, for scarlet fever from 200 to 63, for diphtheria from 384 to 261 and for whooping cough from 798 to 237.

THE MALARIA TREATMENT OF DEMENTIA PARALYTICA

The most efficacious treatment of dementia paralytica was inoculation with malaria. With a view to making this treatment generally available, the ministry of health maintained, in cooperation with the London county council a laboratory where mosquitoes were bred and infected with a pure strain of malaria, with the view to making more generally available this form of therapy. During 1935 the laboratory complied with 318 requests for mosquitoes from 188 hospitals in England and Wales and also supplied hospitals in Germany, Austria and Rumania.

TUBERCULOSIS

Nearly 30,000 persons were certified to have died from tuberculosis in 1935, but this was 11,000 fewer than ten years ago. Only a few years ago the word tuberculosis was taboo and people put off consulting physicians after they suspected they had the disease for fear that their suspicions would be confirmed. That attitude was gone and in most cases tuberculosis could be cured if advice was taken in time.

MENTAL DISEASE

In no branch of public health had such a striking change been effected in recent years as in the mental disease service. Not many years ago mental disease was treated almost as a criminal offense. The whole atmosphere and outlook of mental treatment had been transformed. Occupational therapy and recreations were playing an increasingly important part in the treatment. The first five years of the act which enabled voluntary patients to be received in public mental hospitals had produced a striking result. The voluntary admissions had risen from 7.1 per cent of the total admissions to 24 per cent in 1935.

A NATION OF MEDICINE DRINKERS

One aspect of health affairs could not be regarded with satisfaction. Our unquenchable medicinal thirst continued and it was suggested that we were becoming a nation of confirmed medicine drinkers. In Scotland physicians had never adopted the custom of dispensing medicines and their patients had not been induced to consider a bottle of medicine a necessary corollary to a visit to the physician. In England, on the contrary, for generations physicians had with few exceptions dispensed medicines and the patients had come to regard a visit to the physician as synonymous with the receipt of medicine. The cost in England of providing medicine for the insured population exceeded by 50 per cent that in Scotland and there were no facts in the incidence of disease in the two countries to account for the difference. Nor would any one suggest that the standard of treatment of the Scottish physicians was lower. In 1934 fifty-seven million prescriptions were dispensed under the health insurance acts.

Protection Against Poison Gas

Major H. S. Blackmore, medical adviser to the air raids precautions department, assisted by police officers conducted a demonstration at the Metropolitan Police College of mobile gas chambers that are to be used in schemes of anti-gas training. The chambers are motor trucks with specially constructed gas-tight bodies, in which a gas cloud can be created. For training purposes a form of tear gas that causes no serious injuries will be used. It is intended to place forty trucks on the road and send them to every part of the country. Their use will be permitted only by a fully qualified instructor. They are intended for the training of persons in essential services, such as police and firemen. A new civilian gas mask has been manufactured in millions. It is of simple construction and weighs only 20 ounces. If need arises the masks will be distributed free to the population. Meanwhile they can be bought for \$1.50.

At the meeting of the representative body of the British Medical Association, which has begun at Oxford, the following resolution was submitted: "That the representative body is of opinion that any protective measures for the general population against chemical warfare can only be very imperfect and inadequate. Inasmuch as chemical warfare will cause untold suffering and impairment of health physically and mentally, with destruction of life, it should be proclaimed illegal. In the interests of humanity the British Medical Association should take the initiative with a view to securing the cooperation of the medical profession of all countries in order to prohibit the manufacture of poison gas." In the discussion the inadequacy of the protective measures which the government is taking

was disputed. The resolution was defeated and the following amendment was carried "That this meeting condemns unreservedly the use of poison gas in warfare as inhuman in its results and degrading to civilization and relies on the council to do everything in its power with a view to securing the cooperation of the medical profession of all countries in order to prohibit the use of poison gas"

Presentation to Lord Moynihan

A presentation was made at the Royal College of Surgeons to Lord Moynihan by the subscribers to the *British Journal of Surgery*, in appreciation of his services to that journal since its foundation in 1913. Professor Hey Groves, who has been editorial secretary during the entire period, paid a tribute to Lord Moynihan's work for the science and practice of surgery. He mentioned particularly his leadership in three movements—the foundation of the Surgical Club, which now bears his name, the *British Journal of Surgery* and the Association of Surgeons of Great Britain and Ireland. He handed to Lord Moynihan a silver statuette of a young man standing on a crystal globe and holding above his head an open book of gold bearing the words "The British Journal of Surgery, 1913-1935." Sir D'Arcy Power, on behalf of the subscribers, handed to Lord Moynihan a check for \$5,000, who presented it to the president of the college to be expended on surgical research. In his reply Lord Moynihan referred to his efforts to break down barriers that existed between centers of surgery and between individual centers at home and abroad.

Cause of Death in Intestinal Strangulation

Intestinal strangulation had been investigated in the laboratories by Mr. G. C. Knight and D. Slome. They had shown that the cause of death was the formation of a toxin, which was produced in from thirty to forty-five minutes after strangulation. The toxin might pass into the lumen of the intestine and later into the peritoneal fluid. For a period varying from a few hours to twenty-two hours, toxin could be obtained in sufficient quantity to kill a normal animal. Strangulation did not produce death by loss of fluid into the intestine but by production of some poison in the intestinal wall.

Experimental Syphilis in Mice

At the May 12 meeting of the Académie de médecine, Professor Levaditi presented the results of the experiments of two of his associates, Stroesco and Vaisman, which represent a new study of experimental syphilis clinically nonapparent, of mice. This research was based on histologic methods, much more advanced so far as technique is concerned than any employed up to the present time. "Experimental syphilis in mice without the slightest clinical evidence hence termed nonapparent," is shown, as the result of this study, to be a generalized spirochetosis of the entire reticulo-endothelial system. The animal apparently normal is in reality a veritable living culture of spirochetes. The latter invade the connective tissue of the epidermis and dermis, the glands, the periosteum and the peripheral nerves which conduct the spirochetes directly to the spinal ganglia without giving rise to any histologic changes. In mice syphilis is primarily and exclusively not a lymphangitis; the propagation of the spirochetes beginning at the site of inoculation in the epidermis and invading progressively the deeper layer of the skin (including the hair follicles) so rapidly that as early as the thirty-fifth day all the cutaneous structures are full of spirochetes. In the dermis they develop along the connective tissue fibers attaching themselves to the

vessels of the dermis, where they continue to multiply and invade adjacent structures. Not a single cutaneous area is free, including the skin of the tail, trunk, neck and head. The mucous membranes are also invaded and at the base of the dermis areas are to be seen in which the number of spirochetes exceeds that observed at times in the syphilitic chancre of rabbits. The cartilage and periosteum of the mouse are constantly infected. The invasion of the nerves takes place rather late, at about 100 days, either in the perineurilemma or less often in the interior of the dermic nerve ramifications. One can follow the spirochetes into the nerve roots, where they are relatively infrequent, as far as the nerve centers. The absence of any inflammatory reaction even in foci in which thousands of spirochetes are visible, is striking.

Pulmonary Arteriography

The attempt to develop new methods of diagnosis with the aid of arteriography (injection of opaque mediums into the general circulation) is well exemplified by the technique of Moniz, Carvalho and Lima. This consists in the introduction of an opaque ureteral catheter under roentgenoscopic control into a vein at the bend of the elbow as far as the right auricle. From 8 to 10 cc. of a 120 per cent solution of sodium iodide is injected and a roentgenogram is taken immediately. An image of the entire pulmonary arterial circulation is thus obtained which permits a detailed study of the luli, thus avoiding errors in the interpretation of ordinary roentgenograms.

At the May 1 meeting of the Société médicale des hôpitaux, Ameuille and his associates reported their experience in the employment of pulmonary arteriography in diseases of the lung on the one hand and in exploration of the mediastinum and pulmonary circulation on the other. In areas affected by pulmonary tuberculosis the blood vessels are scarcely visible and in advanced cases there seems to be a complete absence of any circulation. This picture is especially frequent in cases of pulmonary abscess. In a number of cases of bronchiectasis the images are indistinct. In a case of cancer of the lung there was a complete absence of vessels, which confirmed the observations following injection of iodized poppy-seed oil into the bronchi, at which it was noticed that none of the opaque medium entered the involved area. In cases of artificial pneumothorax one could easily demonstrate that the circulation was slower and considerably less active. By modifying the original technique the authors were able to identify the pulmonary artery and its ramifications as well as to obtain an excellent picture of the right ventricle and also the infundibulum and trunk of the pulmonary, thus facilitating greatly the interpretation of oblique views of the mediastinum. No serious complications have ever been observed during or after this method of pulmonary arteriography. A severe transitory headache was the only after-effect ever noted.

In the discussion Laubry stated that he had employed the method on the cadaver but hesitated to apply it clinically, especially in patients with cardiovascular disease. Justin Besançon had found it difficult to introduce the ureteral catheter as far as the right auricle through a vein of the left arm. One can easily push the catheter beyond the right auricle into the subhepatic veins in cadavers and also in dogs as a result that might be utilized as an extension of the angiographic method of diagnosis. He had never employed the technique clinically. Etienne Bernard said that the method allowed one to distinguish in the mediastinal shadow the bronchial and pulmonary from that due to the vascular components. Ravina found that in dogs the hilar images were in reality those of the blood vessels in the majority of observations. Ameuille believed that there was little risk of serious complications in using the method. It also shows the marked tolerance to iodine if given by certain routes.

Additional Cases of *B. Funduliformis* Septicemia

Septicemia due to *Bacillus funduliformis* appears to occur more frequently than formerly thought, since the clinical picture becomes better known and the identification of the bacillus more perfected. At the May 8 meeting of the Société médicale des hôpitaux, Donzelet, Meyer and Olivier added two recently observed cases. The first patient was a man, aged 26, who had severe chills and high temperatures about ten days after a pharyngitis. The day after the onset of the chills, an arthritis of the right knee was noted and thought to be of gonorrheal origin. The joint pain disappeared but the chills and fever continued for the next ten days, accompanied by a marked icterus. The latter symptom led the authors to make a blood culture in which *Bacillus funduliformis* was found. Death occurred about two weeks after the onset of the chills and fever. The necropsy revealed numerous pulmonary abscesses varying in size from a lentil to a filbert. The pus showed on culture and stain the same bacillus as found in the blood during life. The pulmonary condition had not presented any physical signs clinically. The liver was greatly enlarged but there were no foci of suppuration. On histologic study the parenchyma showed the typical changes of a degenerative hepatitis.

The second patient was a woman aged 26. The clinical picture at the onset was that of a tonsillitis accompanied by severe pain along the left carotid sheath. Chills and fever (to 104 F) appeared two days later and on admission to the hospital, the third day after the onset, the patient appeared extremely ill. She complained of severe pain in the left side of the neck. The objective signs were a slight bronchitis, a left pleural effusion and an arthritis of the left knee. The blood culture in an anaerobic medium four days after the appearance of the tonsillitis, revealed a very large number of colonies of *Bacillus funduliformis*. The patient died the same day and the necropsy revealed, as in the first case, many foci of suppuration in the lungs and a thrombosis of the left jugular vein of antemortem origin.

In animals, multiple abscess of the liver is frequently observed in *B. funduliformis* septicemia but this has been reported in only two clinical cases, and in only one of these did icterus occur as in the first of Donzelet's patients. The second case illustrates the pulmonary clinical type with subacute evolution so well described by Pham-Huu Chi in his thesis. Death occurred on the third day of the septicemia, the main clinical features being the pleuropulmonary and arthritic changes. According to most authors the venous (jugular) thrombosis seems to be a link between the tonsillitis and the rapidly fatal generalized infection, as in Donzelet's second patient.

Injectations of Histamine for Rheumatism

As a result of the reports of Deutsch, histamine has been used extensively in chronic rheumatism. At the May 1 meeting of the Société médicale des hôpitaux, Weissenbach and Perles stated that, if one injects the histamine solution intradermally instead of into the muscles, the pain of the latter method can be avoided. A solution containing 0.5 mg of histamine hydrochloride per cubic centimeter is used for each sitting, the average dose injected being from 0.25 to 0.5 mg to which a local anesthetic (phenylpropionate of para-aminobenzoilamino-ethanol) in the proportion of 0.5 mg to the same amount of histamine is added.

A special 1 cc. syringe graduated in 0.05 cm and a very fine needle such as one uses for intradermal reactions is essential to inject into the dermis of the region as close as possible to the seat of pain. A series of two to ten injections is given every day or every second day, according to the results obtained. The relief of pain is almost immediate and may be permanent

after the first injection, but it may recur after an interval of from six to eighteen hours. Repetition of the injections appears to have a cumulative effect. The muscular contracture and functional disability disappear in direct proportion to that of the cessation of the pain.

So far, forty-one patients suffering all types of acute but especially of chronic rheumatism have been treated. The treatment has been successful, after the first injection, or at least during the first week, in 85 per cent of the cases. At times, painful contractures of several months' and even years' duration disappeared after two or three treatments, often after a single treatment.

This report was followed by detailed histories of forty-one cases in which the treatment had been used.

July 6, 1936

Secretion of Milk an Indication That the Fetus Has Died

Before the Medical Society of Königsberg, K. W. Schultze described an indication by which the death of a fetus may be established. The growth of the mammary glands during pregnancy is regulated hormonically by the anterior lobe of the hypophysis and by the placenta. While the placenta remains connected with the maternal organism, the mammary glands secrete only colostrum. Lactation is first set in motion when through cessation of placental function a shifting takes place in the hormonal equilibrium of the woman. It is therefore immaterial whether the placenta is expelled normally or remains detached within the uterus, in both cases lactation begins after about two days. This is true also in abortions. From his observation of 100 cases, Schultze became convinced that the secretion of milk during pregnancy and in abortions is indicative of a cessation of placental function and therewith the extinction of life in the fetus. When in hemorrhagic miscarriages the cervical canal is closed, it is difficult to distinguish between an abortus imminens and an abortus incompletus. If in such cases milk can be detected which was not secreted during a preceding period of lactation, the death of the fetus has occurred and its removal is then indicated. Should breast milk suddenly appear in a pregnant woman presenting an infection with high fever, it is to be interpreted in the same manner. The appearance of colostrum, on the contrary, merely indicates the survival of hormone producing chorial elements. Colostrum may be secreted too in cases in which the greater part of the placenta has been loosened by hemorrhagic abortion and the fetus has died. If these data are to be taken as valid, a great saving might result, since futile attempts to combat hemorrhage would not be made in cases in which the fetus has died.

Communications on Cancer in Germany

In a paper submitted to the Leipzig Medical Society, Klemm states that cancer in childhood is not so infrequent as it is assumed to be. Klemm described three cases observed by him. Two of these were cases of intestinal carcinoma in which correct diagnosis was made only post mortem in the first case and after a third operation in the second case. The incorrect diagnoses in the foregoing cases were 'intestinal tuberculosis' and 'appendicitis' respectively. The first patient was a girl aged 10, the second a boy, aged 14. In the third case a girl not quite 8 years old presented a melanotic tumor the size of an apple above the right eye together with xeroderma pigmentosum. The child had already undergone repeated facial operations for malignant neoplasms. She had also received roentgen treatment. Metastases were not present. Of Klemm's

three cases, the first and third ended fatally, the second child is still undergoing operative treatment.

The digestive tract is the favorite seat of childhood carcinoma. Symptomatically the disease scarcely differs from its manifestation among adults. Opinion is divided on the degree of malignancy, however, infantile cancer in the digestive tract (exclusive of the rectum) seems to be distinguished by a singularly rapid course.

The greater incidence of cancer in older persons is explained to some extent by Freund and Kammer's observation that the power of the blood serum of the young to destroy the cancer cells is greater. In nurslings this power is twenty-one times greater and in older children from four to sixteen times greater than in adults. To what this more powerful defense mechanism in the blood of children and infants is due, no one knows. The question of heredity cannot be answered with certainty excepting in cases of skin cancer accompanied by xeroderma pigmentosum.

A statistical cancer survey was instituted by the National Anticancer Commission, Oct. 1, 1933, on which date work began in many different sections of Germany. The entire project will require five years. Confidential "cancer case cards" and "cancer death cards" are employed. A preliminary report has just been published at Nuremberg covering the first year of the survey up to Oct. 1, 1934. The uniformity of the census and the evaluation of the material have been to a great extent guaranteed. In Nuremberg, with about 420,000 population, the following data for the specified year were acquired from physicians and institutions for the sick. There were 1,345 cases of malignant growths recorded, 492 of the patients were men and 853, or nearly twice that number, were women. This means a cancer morbidity of 2.6 per thousand male inhabitants and of 3.9 per thousand female inhabitants. In the higher age groups the increase in cancer morbidity ran somewhat parallel for the two sexes. Prominent among the men was stomach (151 cases) and intestinal cancer (127 cases), a total of 62.33 per cent of all cancer cases occurring in males. In twenty-two instances, pulmonary and bronchial cancer was found in males. Among females, 164 cases of stomach cancer and seventy cases of intestinal cancer (a total of 234 cases) were ascertained. The uterus was the most frequent seat of cancer among women (256 cases). Only twelve women presented pulmonary and bronchial cancer. Carcinoma of the mammary gland was found in 149 women but in only three men. Sarcomas and other malignant neoplasms were found in forty-six men and sixty women. Of 492 male cancer patients in the year covered by the report 255 died in the course of the same year, while of 853 female patients with cancer 341 died.

Postmortem statistics shed light on the frequent assertion that the increase in the number of tumor cases is the result of more accurate diagnoses. The data were gathered by Dr. W. Hausladen from the postmortem material of the Pathologic Institute of the University of Munich. From 1912 to 1921 a total of 12.19 per cent false diagnoses with regard to cancer were recorded, against 19.67 per cent in the years 1922 to 1931. The largest number of false diagnoses concerned the gallbladder and the pancreas. From 1922 to 1931 a manifest deterioration took place in the ability to recognize carcinoma of the intestine, breasts, ovaries, liver, urinary bladder and thyroid body. During the same period improvement appeared in the ability to detect carcinoma in the rectum, pancreas, gallbladder, larynx, bronchi and lungs.

Of interest for the question of hereditary taint in persons with tumors is a statistical report made public by the Karlsruhe Life Insurance Bank. These records show that of 636 tumor cases among persons insured by the organization, 13.2 per cent showed a history of malignant growths in parents or in siblings.

Maxillary Actinomycosis

Professor Axhausen stated before the Berlin Medical Society that maxillary actinomycosis presents the clinical picture of a hard-as-a-board infiltration of the soft parts. The disease is not rare but a majority of cases are not diagnosed. It is from observation of the advanced stage that the classic clinical picture has been formed. The early stage presents an extraordinarily varied form. Early diagnosis is indispensable to rational therapy. It is significant that maxillary actinomycosis never is an independent disease entity but always owes its existence to a pyogenic mixed infection. Primary pure actinomycosis is possible only on the palate and the tongue. Primary disease of the jaw, however, is invariably due to pyogenic infection from some tooth or from some pocket in the alveolar process, which in turn may be traced to a submucous abscess or to an acute osteomyelitis. Frequently the pyogenic cocci prepare the way for the actinomycotic granules in the oral cavity, which, after infiltration, may make progress aided by the bacteria. Since all types of dental infection can be accompanied by actinomycotic mixed infection, microscopic examination of the scraped out granulations and not of the pus alone is necessary in all cases. In chronic cases roentgen irradiation of the areas should accompany surgical treatment. Because of the impossibility of the scraping operation in acute cases, intervention is limited to opening of the abscess. In such cases the great number of residual granules leads to numerous new abscesses. Mild roentgen dosages are more effective than the stronger. The procedure yields good cosmetic results and robs actinomycosis of its fearful character. Fatal cases no longer occur.

Prof. Gustav Aschaffenburg 70 Years Old

One of Germany's most prominent psychiatrists, Gustav Aschaffenburg, completed his seventieth year May 23. He served for ten years as assistant to Kraepelin, then director of the Heidelberg psychiatric clinic. Young Aschaffenburg shared the labors of the great research scholar, who at that time was laying the groundwork for the Kraepelin revised classification of mental diseases. Aschaffenburg soon came to be interested in questions involving the relationship between jurisprudence and psychology. As prison physician and later as director of a large clinic at Cologne, he was able to make important contributions to our knowledge of this sphere. Already at an early date his work on "Crime and Its Prevention" enlisted the attention of wider circles and was translated into English. Aschaffenburg was a prominent member of the International Criminological Association. His theories found further expression in the *Monatsschrift für Kriminalpsychologie und Strafrechtsreform*, which he edited for nearly thirty years, till 1935. Among his other numerous publications one has only to mention the well known "Psychiatry and Criminal Law." For nearly thirty years Aschaffenburg carried on as one inspired and as an inspiring teacher, esteemed physician and successful research worker. In 1911 he organized the seventh International Congress of Criminal Anthropology.

Visual Disturbances in Air Service Candidates

As Dr. Hoffmann stated before the Medical Society of Königsberg, the crucial test of the fitness of recruits for the national air forces is the condition of the vision. Candidates in whom there is even a temporary failure of so-called stereoscopic vision are considered unfit for service as aviators. Tests for strabismus have disclosed that less than 10 per cent of all candidates are free from this defect. In shortsightedness and wide interocular spacing the accommodation must be greater and divergent strabismus is thus furthered. The reverse is true in farsightedness. The last named condition plays as yet no part in the air service examinations. In testing for defective convergence it is observed that weakness of divergence is more apparent when the eyes are tested from a near point.

weakness of convergence, on the contrary, is better observed from a distant point. The Americans maintain the most rigorous standards in the selection of fliers; they still differentiate between convergent and divergent strabismus.

The normal adjustment of the eyes in the same direction is designated as "orthophoria." Disproportion due to the development of the muscles, the facies and the blood and fat content leads to "heterophoria." Hoffmann has to date made visual examinations to determine the fitness of 1,822 fliers. From this material he gathered the following data: Orthophoria was present in only 171 men (9.4 per cent), defective convergence in 352 (19.4 per cent), defective divergence in 1,299 (71.2 per cent). In twenty-five men (1.37 per cent) deficient stereoscopic vision was present. Divergence is frequently encountered but is regarded as negligible, since it is seldom linked with other complications.

Discussion of Taxation of Practitioners and Hospitals

Prof. Masao Kambe of the department of economics of the Kyoto Imperial University, one of the highest authorities on taxation in Japan, said in a recent paper that from the standpoint of taxation, medical practice and the general attitude of physicians toward their patients may well be reconsidered. At present two kinds of taxes are imposed on medical practice. One is the registration fee, the other a business tax. The former is a small sum paid only once when a physician is registered. The latter is imposed on profit-making business but has not yet been imposed on the individual practitioner. The reason is that medical practice deals with life, something mysterious, spiritual and noble, also medical treatment depends more on the individual's mental training than on equipment or apparatus. But of late medical practice has shown a tendency toward profit making. The buildings are more attractive than before, and widespread advertisements are always inviting patients. In administering a medicine, more than necessary, might be prescribed or sold, while too many patients are advised to go to the hospital where they have to pay for room and board besides medical treatment. In such a case it is almost the same as a profit-making business with a big capital. It is therefore natural that such business-like transactions should produce a profit that might be taxed. Indeed, some practice may be said not to differ at present in some respects from the business of boarding houses, hotels and manufacturing. Even religion is coming to be abused as a means of raising profit. Medical institutes or hospitals today, besides administering medicine, injections and treatment, sometimes have several hot springs attached to them thus providing recreation, often electrotherapy and other treatments are available and their management is going more and more into minute and exhaustive details.

The present system of taxation on medicine in Japan is divided into the following kinds. First, on the private practitioner, who must pay an income tax, a capital levy, a land tax and a house tax with its surtax. Second, on the hospital incorporated for making profit. Third, on a hospital incorporated for public welfare, which must pay a land tax with its surtax. Governmental hospitals are not taxed. There is much doubt whether such a discriminative taxation is right, for instance, a corporation hospital for public welfare may easily, consciously or unconsciously, raise profit. In such a hospital at present it is loudly announced that medicines and other services are given at a net price. The charge is 10 sen a day for medicine. When compared with the rule of the Japan Medical Association, it is cheaper by from 15 to 25 sen, but the true cost price is said to be only 3 sen for medicine. The charge for injection also has some profit in it and in some

hospitals the time required in examining patients, according to their reports, averages three minutes and forty seconds per patient, which is not a great deal of labor and time if compared with thirty or forty minutes, which is the usual time for an examination on an ordinary occasion. This fact shows that even a hospital for public welfare may easily make some profit by will or by chance. On the contrary, the hospital operated for profit may limit its profit and keep it to not more than the interest on the bonds, while the surplus may be used to improve the equipment. Judging from these facts, it is difficult to estimate whether a certain hospital is benevolent or operated for profit. There are also two kinds of individual practitioners: one is benevolent, the other is avaricious. When a doctor is an employee or has no hospital or office of his own but merely makes a professional visit to patients, he ought to be free of all taxes. But profit making is the object of most practitioners. A strong objection to imposing taxes on doctors is that it means levying taxes on the lower classes. In fact the poor are obliged, under present circumstances, to take "patent medicines" because they cannot afford to consult physicians. Consequently the taxes will generally be imposed on the middle and upper classes. Others say that this tax will increase the cost of living. This is perhaps a groundless fear. Therefore, besides the income tax, a business tax should be levied on practitioners as well.

The Number of Poisonings During 1935

According to the figures of the Home Office, the number of persons poisoned during 1935 was 14,942, of which 8,515 were cases of intentional poisoning (56.98 per cent), 6,392 were cases of accidental poisoning (42.78 per cent). Phosphorus poisonings numbered 2,023, resulting in 1,170 deaths, the highest death rate. There were 1,041 poisonings from various "patent medicines," with 190 deaths. Mercury killed 118 of 221 persons who took it. Of 113 persons who took cyanic acid ninety-six died.

A New Department of Health and Sanitation

Recently at a cabinet meeting the ministers of the army and of the navy suddenly proposed the establishment of a department of health and sanitation. It is strange that this proposal was not made by the minister of home affairs under whose management has come almost all the important health measures. This is because the military medical bureau has for years been desirous of an independent department to exercise general control over all medical matters, which are now handled by many sections and branches in several departments. What prompted the army and navy most was the physical examinations for conscription in recent years, which showed a decline in the physical condition of young men. In the five years from 1922 to 1926 about 250 per thousand of those examined failed to pass the physical examination for conscription. In the five years from 1927 to 1932, about 350 failed, while in 1935 about 400 per thousand young men failed to pass the examination. In the examinations it was found that the height of the young men was much improved compared to former days, but that their weight has not improved correspondingly. There are now found about fifteen times as many cases of tuberculosis as there were thirty years ago. The increase in near-sightedness among school boys is surprising. The authorities believe that the cause of such a decline in health can be justly attributed not to the want of physical education, to shortage of nutrition or medicine or to overwork, but chiefly to the poor health of the mother. From the standpoint of national defense, the army and the navy urgently desire to establish a new independent department devoted to the reconstruction of the national physique. The Japan Medical Association held a special meeting concerning this problem in Tokyo to help the army and navy in this movement, and it seems to be only a matter of time till the new plan will be realized.

Marriages

JAMES ADAMS HAYNE JR Congaree, S C, to Miss Lorraine Evelyn Stahl of White Plains, N Y, in New York, June 30

MORTON MORRIS PINCKNEY, Richmond, Va, to Miss Louise Lippitt Sinnickson of Bryn Mawr, Pa, May 16

WILLIAM ROLLAN HILL Charlottesville, Va, to Miss Sherard Pierson Parrish of Richmond, May 16

CHARLES DONALD LORD, Montclair, N J, to Miss Ruth Eleanor Henderson of Bloomfield, June 13

BENNETT WATSON ROBERTS Durham, N C, to Miss Elizabeth Walton Parker in Norfolk, Va, May 28

EUGENE BEVERLY FERRIS JR, Cincinnati, to Miss Charlotte Gordon Hopkins of Dover, Mass, June 6

CHARLES JACK FISHER, Moulton, Ala, to Miss Margaret Zeigler of Birmingham, May 29

BENJAMIN D PARISH JR, North Hills, Pa, to Miss Hanna A Yost of Norristown, May 28

JEFFERSON BISHOP KISER to Miss Margaret Mahood Johnston, both of Emporia, Va, June 1

HAROLD B TURNER, Bloomfield, Ind, to Miss Essie Katherine Rarden of Lyons, May 28

CHESTER L RILEY, Richmond, Va, to Miss Verna Parker of Powhatan, June 8

Deaths

James Meschter Anders ☉ emeritus professor of medicine at the University of Pennsylvania Graduate School of Medicine, Philadelphia, died, August 29, at his summer home in Blue Hill Falls, Maine, aged 82. Dr Anders was born in Fairview Village, Pa, July 22, 1854. He received a medical degree from the University of Pennsylvania Department of Medicine, Philadelphia, in 1877, in which year he also received the degree of doctor of philosophy. For many years he was professor of theory and practice of medicine and clinical medicine at the Medico-Chirurgical College of Philadelphia, which became the Graduate School of Medicine of the University of Pennsylvania where he was for many years professor of medicine and clinical medicine and later emeritus professor. He was chairman of the Section on Practice of Medicine of the American Medical Association from 1900 to 1901, a life member of the Academy of Natural Sciences, a member of the American Clinical and Climatological Association, the Association of American Physicians, and many other scientific and civic societies. past president of the American College of Physicians, the College of Physicians of Philadelphia and the Pennsylvania Tuberculosis Society. At various times Dr Anders was a visiting physician to the Protestant Episcopal Hospital, physician to the Medico-Chirurgical Hospital, consulting physician to the Jewish Hospital, Philadelphia and the Widener Home for Crippled Children, and Asylum for Insane, Norristown, and for many years member of the visiting staff and later member of the advisory board of the Philadelphia Hospital. He was president and formerly vice president of the board of trustees of the Perkins School, Pennsburg, president of the board of trustees of Ursinus College, and member of the board of managers of the City Parks Association and the board of health of Philadelphia. Dr Anders was the author of a textbook known as the "Principles and Practice of Medicine" which passed through fourteen editions, and co-author of "Textbook of Medical Diagnosis." In 1923 he was made a Chevalier of the Legion of Honor of France. In 1928 he was awarded the degree of doctor of science by the University of Pennsylvania and in 1929 the honorary degree of doctor of laws by the Pennsylvania Military College. various other honors were conferred on Dr Anders during his long and distinguished career.

William Henry Mayer ☉ Pittsburgh University of Pennsylvania School of Medicine Philadelphia 1912 member of the House of Delegates of the American Medical Association in 1920 and from 1922 to 1935 past president of the Medical Society of the State of Pennsylvania past president and secretary of the Allegheny County Medical Society fellow of the American College of Physicians member of the American Psychiatric Association and the Association for Research in Nervous and Mental Disease associate professor of neurology University of Pittsburgh School of Medicine aged 49 attend-

ing neurologist to the Passavant and Allegheny General hospitals and Pittsburgh Diagnostic Clinic, psychiatrist to St. Francis Hospital, where he died, August 23

Clyde Yeager Beard ☉ Cheyenne, Wyo, University of Louisville (Ky) Medical Department, 1905, president of the Wyoming State Board of Medical Examiners past president and secretary of the Wyoming State Board of Health, formerly councilor of the Wyoming State Medical Society, served during the World War, local examiner for the U S Veterans' Bureau from 1919 to 1923 fellow of the American College of Surgeons, formerly county coroner, aged 55, on the staff of the Burns (Wyo) Hospital and the Memorial Hospital of Laramie County, where he died, July 2, of peritonitis following an operation to remove the stump of the appendix.

Alva Porter Stoner ☉ Des Moines, Iowa, St. Louis College of Physicians and Surgeons, 1891, past president of the Iowa State Medical Society, formerly professor and head of the department of obstetrics, and assistant professor of surgery and clinical surgery in the Drake University College of Medicine, at one time professor of oral surgery and professor and head of the department of physiology in the Drake University Dental Department, served during the World War, fellow of the American College of Surgeons, surgeon to the Iowa Lutheran and Broadlawn General hospitals, aged 68, died, May 31, of aneurysm.

Martin John Synnott ☉ Montclair, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894, served during the World War colonel in the Medical Officers Reserve Corps of the U S Army, fellow of the American College of Physicians, formerly a member of the city board of health and a member of the county milk commission, visiting physician to St. Vincent's Hospital, consulting gastro enterologist and director of the proctologic department Midtown Hospital, aged 67, died, July 15, of cerebral hemorrhage.

Francis Ingersoll Proctor ☉ Santa Fe, N M, Harvard University Medical School, Boston, 1892, member of the Massachusetts Medical Society, consultant in trachoma to the Indian Service formerly on the staffs of the Massachusetts Eye and Ear Infirmary, the Boston City Hospital and Carney Hospital Boston, and the Perkins Institution and Massachusetts School for the Blind, Watertown, Mass, aged 71, died, July 8 in the Albert Merritt Billings Hospital, Chicago, of infected subdural hematoma and leptomeningitis.

Michael Francis Fallon ☉ Worcester, Mass Harvard University Medical School, Boston, 1887 past president of the Worcester District Medical Society and formerly vice president of the Massachusetts Medical Society, member of the New England Surgical Society, fellow of the American College of Surgeons, at one time member of the Massachusetts State Board of Registration in Medicine surgeon in chief to St. Vincent Hospital, aged 72, died, June 24, of arteriosclerosis and myocarditis.

Rufus Benjamin Weaver, Philadelphia Eclectic Medical College of Philadelphia, 1863, Penn Medical University, Philadelphia 1865, demonstrator of anatomy in 1869, lecturer on regional anatomy from 1876 to 1896 and later professor of anatomy and professor emeritus at the Hahnemann Medical College and Hospital of Philadelphia, in 1888 dissected and mounted the entire cerebrospinal nervous system, aged 95, died July 15, of arteriosclerosis.

Walter Games Bogart, Chattanooga Tenn University of Tennessee Medical Department, Nashville, 1883, member of the Tennessee State Medical Association past president of the Chattanooga and Hamilton County Medical Society at one time professor of diseases of women and obstetrics at the Chattanooga Medical College, aged 78, for many years on the staff of the Erlanger Hospital, where he died, July 9 of hypostatic pneumonia.

Herschel Benoni Cummins, Seward, Neb University of Nebraska College of Medicine Lincoln 1885 member of the state board of health 1897 to 1901 and from 1907 to 1915 formerly member of the state legislature member of the county insanity commission for forty-four years, at one time taught physiology and hygiene at Cotner College Lincoln, aged 77 died June 30 of carcinoma of the rectum.

Othello Clayton Bishop, Port Townsend, Wash University Medical College of Kansas City Mo 1912 member of the Washington State Medical Association served during the World War at one time connected with the U S Marine Health Service formerly on the staff of the U S Marine Hospital number 17 aged 49 died June 8 in the U S Marine Hospital Seattle of cardiac disease.

James Seferen Ennis, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, formerly professor of laryngology and rhinology, Fordham University School of Medicine, consultant in laryngology and rhinology at the Fordham Hospital, aged 66 died June 1, in the New York Post-Graduate Medical School and Hospital, of chronic nephritis

Anna Dwyer \oplus Chicago, Northwestern University Woman's Medical School, Chicago, 1896, formerly medical examiner of the public schools and physician to the Municipal Courts, at one time president of the staff of the Mary Thompson Hospital and on the staff of the Chicago Municipal Hospital, aged 63, died, June 10, in the Columbus Hospital, of cerebral hemorrhage and hypostatic pneumonia

Harry Albert Singer \oplus Chicago, Rush Medical College, Chicago, 1922, associate professor of medicine University of Illinois College of Medicine, member of the Central Society for Clinical Research, on the staffs of the Cook County Hospital, University Hospital and the Research and Educational Hospital, University of Illinois, aged 40, died, August 21, of hypertension and acute pericarditis

Michael Edward Flaherty, Jersey City N J, Jefferson Medical College of Philadelphia, 1906 member of the Medical Society of New Jersey, during the World War was in charge of the sixth medical inspection district and was connected with the exemption boards of the city, from 1910 to 1917 visiting physician to the City Hospital, aged 58, died, June 12, of lobar pneumonia

Frank P. Dohearty, Appleton, Wis., Northwestern University Medical School Chicago, 1897, member of the State Medical Society of Wisconsin, formerly city health officer county and city physician for many years for many years on the staffs of the Outagamie County Asylum for Chronic Insane and St. Elizabeth Hospital, aged 64, died, June 18, of myocarditis

Erwin William Exley, Minneapolis, University of Minnesota Medical School, Minneapolis, 1925, member of the Minnesota State Medical Association and the American Urological Association, aged 38, died May 28 in the New York Post-Graduate Medical School and Hospital New York, of bronchopneumonia following an operation for acute appendicitis

Eugene Price Gray \oplus Winston-Salem, N C Johns Hopkins University School of Medicine Baltimore, 1906 past president of the Forsyth County Medical Society, on the staffs of the Heath Memorial Infirmary, North Carolina Baptist and City Memorial hospitals, aged 55, died, June 24, of cerebral hemorrhage and coronary thrombosis

William Lafoy Hall \oplus Seattle, Vanderbilt University School of Medicine, Nashville, Tenn 1890, for five years practiced at Shansi, China, under the American Board of Commissioners for Foreign Missions and later again engaged in missionary work in Suming Sze, China, aged 68, died May 29, following an operation for gallstones

Cadwallader Curry Vinton, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, member of the Medical Society of the State of New York, formerly a medical missionary in Korea at one time managing editor of *Physical Therapeutics* aged 76 died, June 26 in Bellevue Hospital

William Madden Dawson Brentwood N Y University of Maryland School of Medicine, Baltimore 1931 assistant physician on the staff of the Pilgrim State Hospital, aged 31 died June 12, in the Southside Hospital Bay Shore, of injuries received when the automobile in which he was driving was struck by a train

John Francis Luby, New Haven Conn, College of Physicians and Surgeons Medical Department of Columbia College, New York 1878, member of the Connecticut State Medical Society, for many years president of the medical board and on the staff of the Hospital of St. Raphael, aged 78, died, May 31

Irving Deyo Le Roy, Utica N Y Albany (N Y) Medical College, 1883 member of the Medical Society of the State of New York for many years health officer of Pleasant Valley aged 77 died, May 21, in the Masonic Soldiers and Sailors Memorial Hospital of arteriosclerosis

Zebulon J. Spruiell, Jewett, Texas, University of Texas School of Medicine Galveston 1899 past president of the Leon County Medical Society formerly county health officer for many years president of the school board aged 69 died May 22 in a hospital at Dallas

Arthur Taylor Downing \oplus Littleton N H Dartmouth Medical School Hanover, 1903, past president of the Grafton

County Medical Society, fellow of the American College of Surgeons, on the staff of the Littleton Hospital, aged 58, died, June 25, of carcinoma

Willard L. De Wolf, Los Angeles, Jefferson Medical College of Philadelphia, 1879, member of the Medical Society of the State of Pennsylvania, formerly a practitioner in Butler, Pa., aged 80, died, June 19, of arteriosclerosis, mitral regurgitation and nephritis

Howard William Girvin, Marianna, Fla., Syracuse University College of Medicine, 1911, served during the World War, aged 54, formerly on the staff of the Florida State Hospital Chattahoochee, where he died, May 31, of cardiovascular renal disease.

Clarence E. Munn, Marysville Wash Hahnemann Medical College and Hospital, Chicago, 1884, member of the Washington State Medical Association, formerly county coroner, mayor of Marysville and member of the city school board, aged 72, died May 28

Charles Berry Constable, Santa Barbara, Calif University of Maryland School of Medicine, Baltimore, 1883, Hahnemann Medical College of Philadelphia 1884 aged 71 died, June 21, of chronic myocarditis, hypertrophy of the prostate and arteriosclerosis

John Harold Gooding, Boston Tufts College Medical School, Boston, 1915, served during the World War, for many years a medical examiner at the United States Veterans' Bureau, aged 44, died suddenly June 25, of coronary occlusion

Edward Everett, Dushore, Pa Jefferson Medical College of Philadelphia 1868, member of the Medical Society of the State of Pennsylvania, aged 89, died, June 30 in the Robert Packer Hospital, Sayre, of arteriosclerosis and myocarditis

Fred Arad Lampman, Elkhart Ind., Indiana University School of Medicine, Indianapolis, 1917, member of the Indiana State Medical Association, on the staff of the Elkhart General hospital, aged 49, died, May 15, of cerebral hemorrhage

Louis Vincent Clarke, Far Rockaway, N Y Columbia University College of Physicians and Surgeons New York, 1905, on the staff of St Joseph Hospital, aged 57, died, June 5, in Belle Harbor, of carcinoma of the sigmoid

Edmund H. Dorris, Bolivar, Tenn., Memphis Hospital Medical College, 1901 bank president since 1902 county health officer, and since 1914 chairman of the county school board, aged 62, died, June 19, of cerebral hemorrhage

Charles E. Duve, Nordheim, Texas, Memphis (Tenn) Hospital Medical College, 1905 member of the State Medical Association of Texas, health officer of Nordheim, aged 63, died, May 6, in the Allen Hospital, Yorktown

Wray Devere Marr Lloyd, Rio de Janeiro, Brazil, S. A., University of Western Ontario Medical School London Ont., Canada, 1926, connected with the Rockefeller Foundation, aged 33, died June 2, as the result of a fall

Charles McCauley Emmons, Washington, D C, Georgetown University School of Medicine Washington, 1893, member of the Medical Society of the District of Columbia, aged 62, died, May 29, at his home in Suitland, Md

Finis Logan Anderson, Springfield Mo., Kansas City Medical College, 1890, served during the World War, aged 59, died May 13, in the Veterans Administration Facility, Fayetteville, Ark., of chronic myocarditis

Frederick P. Sprague, Wyandotte Mich Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1896, member of the Michigan State Medical Society, aged 68, died, May 30

Edgar Adams Wilson, Meriden Conn University of Pennsylvania Department of Medicine, Philadelphia 1881 aged 82, for many years on the staff of the Meriden Hospital where he died, May 19 of pneumonia

Robert Thomas Dickey, Wynnboro Texas, University of Texas School of Medicine Galveston 1911 member of the State Medical Association of Texas, aged 48, was killed, May 14 in an automobile accident

Russell Felts Hufford, Tip Top W Va Medical College of Virginia, Richmond, 1932 member of the West Virginia State Medical Association, aged 28, died, May 19, in a hospital at Welch, of pneumonia.

Clemens Max Richter \oplus San Francisco, Medizinische Fakultät der Universität Leipzig Saxony Germany 1872, aged 87 died May 19 of cerebral hemorrhage, hemiplegia and arteriosclerosis

Ralph Kilpatrick, Alexandria, La., Tulane University of Louisiana Medical Department, New Orleans, 1885, member of the Louisiana State Medical Society, aged 74, died, May 14, of endocarditis

Otto Henry Gerdes ♂ Eureka, S. D., Rush Medical College, Chicago, 1892, formerly on the staff of the Eureka Community Hospital, aged 68, died, June 29, of cerebral sclerosis and thrombosis

William Louis Hanson ♂ Dallas, Texas, Baylor University College of Medicine, Dallas, 1921, aged 37, on the staff of St Paul's Hospital, where he died, May 21, of a cerebral hemorrhage.

Eugene Lorin Ketchum, Independence, Ore., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883, aged 80, died, June 21, in Portland, of carcinoma of the liver

Charles Manville Pratt ♂ Towanda, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1882, aged 76, died, May 23, of cerebral hemorrhage and arteriosclerosis

Edmund Burke Brown, Cotton Plant, Ark., Louisville (Ky.) Medical College, 1903, member of the Arkansas Medical Society, served during the World War, aged 55, died, May 6

John Robert Smith, Louisville, Ky., Louisville National Medical College, Medical Department State University, 1910, aged 57, died, May 28, of coronary thrombosis and influenza

Joseph Thomas Johnson, Indianapolis, Meharry Medical College, Nashville, Tenn., 1913, aged 44, died, May 24, of mitral insufficiency, pharyngitis and hypostatic pneumonia

William Walker Gatliff ♂ Butte City, Calif., St. Louis College of Physicians and Surgeons, 1884, past president of the Glenn County Medical Society, aged 79, died, May 12

Mary L. B. Wooster, Washington, D. C., Howard University College of Medicine, Washington, 1883, aged 79, died, May 12, of cerebral hemorrhage and arteriosclerosis

William Miles Wallis, Atlantic, Iowa, University of Buffalo, School of Medicine, 1870, formerly a practitioner in Maryville, Mo., aged 88, died, May 11, of cerebral sclerosis

Jacob Louis Krupp, Brooklyn, Long Island College Hospital, Brooklyn, 1906, aged 54, on the staff of the Beth-El Hospital, where he died, May 5, of Hodgkin's disease.

John J. Parker, Merom, Ind., Kentucky University Medical Department, Louisville, 1900, member of the Indiana State Medical Association, aged 63, died suddenly, May 17

Harry William Sampson ♂ Bangor, Maine, Medical School of Maine, Portland, 1906, served during the World War, aged 54, died, May 27, of lobar pneumonia

Walter James Axford, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1904, aged 56, died, May 17, in the Hahnemann Hospital, of lobar pneumonia

Frank Philip Brendel ♂ Sacramento, Calif., University of California Medical School, San Francisco, 1917, served during the World War, aged 48, was drowned, May 24

Frank Warren Johnson ♂ Fullerton, Neb., Omaha Medical College 1894 formerly secretary of the Nance County Medical Society, aged 68, died, May 11, of angina pectoris

Arthur Lemuel Davis, Wyaconda, Mo., College of Physicians and Surgeons Keokuk, Iowa, 1897, aged 62, died, May 20, of diabetes mellitus and heart disease.

Mary Anne Harriss, San Francisco, Cooper Medical College, San Francisco, 1899, aged 71, died May 13, of coronary thrombosis, arteriosclerosis and hypertension

Paul W. Wadsworth, Milan, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1883, formerly mayor of Milan, aged 76, died May 27, of carcinoma of the face.

Newton E. McDannald, News Ferry, Va., University College of Medicine Richmond, 1900, member of the Medical Society of Virginia, aged 74, died in May

Edward William Vietor, Orford, N. H., Regents of University of State of New York 1875, aged 84, died, May 16, of coronary embolism and angina pectoris

George Norman Stockwell, Ventura, Calif., University of the City of New York Medical Department 1891, aged 66, died May 20, of hypernephroma of the kidney

Michael Joseph Hart, Boston, Harvard University Medical School Boston, 1896, aged 64, died May 23, in the Boston City Hospital of cardiac decompensation

Louis Gilbert Altman, Salem, Ore., Hahnemann Medical College and Hospital Chicago 1882, aged 83, died May 19, of coronary occlusion and myocarditis

William Maxey Joy, Kansas City, Mo., Eclectic Medical University, Kansas City, 1907, aged 63, died, May 29, in a local hospital, of cerebral hemorrhage

Katharine W. Ulrich ♂ Chester, Pa., Woman's Medical College of Pennsylvania, Philadelphia, 1899, aged about 66, died, May 18, of arthritis deformans

Vincent B. Beszczynski, Buffalo, University of Buffalo School of Medicine, 1906, aged 63, died, June 4, of chronic myocarditis and arteriosclerosis

Crisoforo Solis, Rio Grande City, Texas, Escuela de Medicina de Nuevo Leon, Monterey, Mexico, 1896, county health officer, aged 67, died in May

John Ross Gilbert, Camden, N. J., University of the South Medical Department, Sevanee, Tenn., 1895, aged 65, died, May 12, of cerebral embolism

Francis Allen Richardson, San Francisco, Baltimore University School of Medicine, 1901, served during the World War, aged 62, died, May 18

James Joshua Herrington, Worley, Idaho, American Medical College, St. Louis, 1893, aged 67, died, May 7, in Coeur d'Alene, of pneumonia

Linn Bardeen Palmeter, Sidney, N. Y., University of Vermont College of Medicine, Burlington, 1891, aged 66, died, May 24, of angina pectoris

Edgar Rufus Boren ♂ Laredo, Texas, Baylor University College of Medicine, Dallas, 1916, aged 45, was killed, May 20, in an automobile accident

Horace Preston Belknap, Prineville, Ore., Bellevue Hospital Medical College, New York, 1886, aged 80, died, May 18, of cerebral hemorrhage

Glenn Arthur Easton ♂ Grand Rapids, Mich., Detroit College of Medicine 1906, aged 58, died, May 22, of pulmonary embolism and phlebitis

Laviro V. Shawver, Corliss, W. Va., University of Louisville (Ky.) Medical Department, 1894, aged 71, died, May 23, of chronic myocarditis

John Sutherland, Britton, S. D., Rush Medical College, Chicago, 1889, county health officer, aged 79, died, May 23, of chronic myocarditis

Elmer Frederic Kinne, San Fernando, Calif., University of Southern California College of Medicine, Los Angeles, 1906, aged 63, died, May 3

Samuel Astley Murray ♂ Holden, Mo., St. Louis University School of Medicine, 1906, aged 52, died, May 12, of coronary thrombosis

George Patrick McCarthy, Buffalo, University of Buffalo School of Medicine, 1909, aged 54, died, May 14, of carcinoma of the esophagus

Robert Carson Butz, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1907, aged 50, died May 4, of angina pectoris

Walter L. Wylie, St. Petersburg, Fla., Hering Medical College, Chicago, 1897, aged 61, died, May 24, in St. Anthony's Hospital

Curtis A. Wherry, Los Angeles, Kansas City Homeopathic Medical College, 1897, aged 63, died, May 23, of basal skull fracture.

John Bure, Hillsboro, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1885, aged 82, died May 3

Rice Knox, Frost, Texas, Kentucky School of Medicine Louisville, 1883, aged 82, died, in April, of cardiorenal disease

Edgar S. Simpkins, Middleburg, N. Y., Albany (N. Y.) Medical College, 1890, died, May 4, of chronic myocarditis

James Matthew Van Der Ven, Moline, Mich., Long Island College Hospital, Brooklyn, 1891, aged 72, died May 3

William B. Leslie, Holladay, Tenn. (licensed in Tennessee in 1889), aged 83, died May 23, of chronic myocarditis

James S. McGeachy, Chipley, Fla., North Carolina Medical College, Charlotte, 1897, aged 67, died May 11

P. Magenheimer, Chandler, Ind., Medical College of Indiana, Indianapolis 1880, aged 85, died May 28

John B. Norris, Dallas, Texas, St. Louis College of Physicians and Surgeons, 1901, aged 62, died in May

Stacy C. Youngman, North Kansas City, Mo., Omaha Medical College 1884, aged 80, died May 14

S. R. Hickson, Fairfax, S. C., Memphis (Tenn.) Hospital Medical College, 1901, aged 60, died May 12

Arthur L. Murphy, Toronto, Ont., Canada, Trinity Medical College Toronto 1892, died May 13

Correspondence

"GARLIC BREATH ODOR"

To the Editor—In *THE JOURNAL*, August 8, appears an article by Blankenhorn and Richards on garlic breath odor which calls to mind an interesting experience of my own, having direct bearing on their contention that such odors are blood borne. When I was an intern at the Kings County Hospital in June 1933 I delivered a woman who had a very decidedly obnoxious garlic odor to her breath. Shortly after the birth the infant was removed to another room and on bending over it to apply silver nitrate to the eyes I was surprised and rather amused to note that the child also had a strong garlic breath odor.

On occasion I have mentioned this to other men and they usually think that I am attempting to be facetious. However, I think this offers an interesting way of corroborating the authors' theory and I am sure that it must be easier to find a garlic eating mother for experiment than a patient with a tracheal fistula.

DOG BITES

To the Editor—On page 433 of *THE JOURNAL* for August 8, Mr. Albert Payson Terhune is quoted as saying that the bite of a healthy dog is only as dangerous as would be a similar wound inflicted by a piece of metal or bone. This is not quite right. I am so fond of Mr. Terhune and his wards that the quotation may be revised. Canines give a vigorous shake to a bite, meaning technically a bruised and lacerated penetrating wound. This would mean debridement in surgical principle plus first aid with chlorine preparations or, better yet, the U S P camphorated oil that saved the lives of patients with compound fracture or opened knee joints in the practical work of our grandfathers in medicine.

ROBERT T MORRIS, M.D., Stamford, Conn.

THE NAMING OF MEDICAMENTS

To the Editor—At the Annual Session of the American Medical Association in Kansas City I discussed briefly the nomenclature of therapeutic substances. The interest I found in the Section on Pharmacology and Therapeutics encourages me to draw your attention and perhaps the attention of some readers of *THE JOURNAL* to this matter. Especially I dealt with the troubles arising from the fact that the same effective substance is called often by different terms. Thus, it happens frequently that the same substance is known in different countries by different names. Furthermore, in the same country different physicians administer the same drug with different names without sufficient information about this fact. Trade-marks through advertising become the common terms for the efficient molecules. The efficient work of your Council on Pharmacy and Chemistry, preventing special names for products except those originated by the discoverer of any preparation, is not effective in foreign countries. Terms proposed by your council are sometimes protected as brands in foreign countries. Experience has shown that as a consequence of this state many papers about the matter of action or the therapeutic value of a new preparation may not be understood in other countries or sometimes even in other parts of the same country, because there another term for the same active principle is better known.

A different matter of nomenclature is the question of therapeutic suggestiveness of a term for a new drug.

It should be possible, I think, to avoid any objection on account of the therapeutic suggestiveness and to find nevertheless a name for the purpose of scientific literature and international understanding for each new substance.

In my opinion it is urgent to have a single distinct name for each distinct substance and to use only this name in all scientific papers of the world. But an agreement with all individuals and communities interested in a special case would not be accomplished without establishment of an international organization or committee. My proposal, therefore, is to establish an international committee studying these problems and elaborating a project of proceeding.

of the Pharmacologic Institute of the
Friedrich-Wilhelms University

SALMONELLA

To the Editor—Research work on *Salmonella supestifer* as the cause of a specific enteritis in swine inclines me to a large interest in the relationship of this organism to diseases of man. The interesting case report of Drs. Cohen, Fink and Gray in *THE JOURNAL*, August 1, is greatly appreciated. If I may presume to do so however, I should like to call to the attention of the authors a misstatement of fact so far as veterinary science is concerned. They say that 'until the World War the *Salmonella supestifer* organism was known to be the cause of hog cholera.' The cause of hog cholera has been known for more than thirty years to be a filtrable virus.

It is true that forty years ago *Salmonella supestifer* (Ann. Rep. B A I, 1885-1889 Special Report B A I, Salmon, 1889) was regarded by many as the cause of hog cholera, but the work by Dorset, McBryde and de Schweinitz (U S D A, B A I, circ 41, 1903 Bull 72, 1905) definitely disproved this and showed that a filtrable agent is the cause of hog cholera and that *Salmonella supestifer* is rather a common associate of the virus. My own work (*J A Vet M A* 25 34-89 [Oct] 1927, 27 345-356 [Feb] 1929) proves definitely that *Salmonella supestifer* is the specific agent of an enteric disease of swine, sometimes associated with cholera but oftener not.

Medicine, Iowa State College

ZIPPER TRAUMA

To the Editor—On a hot Sunday afternoon a man about 28 years of age walked into my office in a topcoat and looking rather embarrassed. The situation became clear when he explained that he neither could raise nor lower his trousers, as his penis was caught in the zipper.

Examination revealed the dorsal portion of the prepuce and part of the glans caught in the zipper. The penis was cleansed thoroughly and the part caught in the zipper was infiltrated with procaine-epinephrine. A catheter was placed in the penis and a triangular wedge was cut out of the glans in order to loosen it. The urethra was not injured. The prepuce was then freed. The edges of the glans were approximated with two silk sutures, the prepuce required five sutures.

The wound healed without eventualities and five days later the stitches were removed.

In this civilized era the automobile has given us some typical fractures of the lower extremities, the airplane the 'pilot's neurosis' and now comes the sartorial danger—the zipper.

MYRON V. SUSSKIND, M.D., Jackson, Mich.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

PROPHYLAXIS FOR SYPHILIS

To the Editor—What prophylaxis would you recommend for intercourse without a condom to prevent syphilis? If a mercury ointment is recommended, what per cent do you suggest? Should only the penis or contiguous areas as well, be covered with the ointment? About what quantity should be used and for how long should it be massaged into these areas? How frequently may the average individual use this method of prophylaxis without local or systemic danger because of the absorption of mercury? Please omit name. MD New York City

ANSWER.—The system of chemical prophylaxis used in the United States Army is adequate for the prevention of syphilis if applied within an hour of exposure. This consists of

(1) A careful washing of the entire genitalia with soap and warm water,

(2) The intra-urethral injection of a 2 per cent solution of strong silver protein or a 10 per cent solution of mild silver protein, retained within the urethra for five minutes (for the prevention of gonorrhea),

(3) The use of 33 $\frac{1}{3}$ per cent calomel ointment in the amount of 4 Gm., rubbed not only on the penis but also contiguous areas as well (i. e., scrotum and pubis) for a period of ten minutes, timed by a watch. Following this, the genitalia are wrapped in toilet paper and the ointment is allowed to remain in situ for several hours.

There would probably be no danger of mercury poisoning either locally or generally if this form of treatment were used daily.

DIAGNOSIS OF SYPHILIS

To the Editor—A man had numerous exposures for many months with a girl who developed secondary syphilis with an eruption and a 4 plus Wassermann reaction before either knew that anything was wrong with her. He developed a small penile sore which he described as a "log cut" which healed in four days without treatment. Then he discovered that the girl was infected and went to his local doctor who gave him one intravenous injection of 0.4 Gm. of neocarsphenamine followed by five weekly intramuscular injections of bismuth salicylate, the last of which was given six weeks ago. The sore developed January 1 and weekly blood tests have all been negative, the last made day before yesterday, six weeks after the last injection of bismuth salicylate. He is very much worried and does not want to take further treatment without knowing whether he was really infected or not. Should I advise active treatment on the assumption that he was infected and leave that uncertainty in his mind or should I take weekly blood tests and wait to see whether the blood becomes positive or not? How long would this small amount of treatment give negative Wassermann reactions? The man is over 50. What treatment would be best fitted for him? Please omit name and address. MD Washington

ANSWER.—This inquiry calls attention to the malicious practice of making a diagnosis of a penile lesion only by inspection. In this case it appears that the original diagnosis of a chancre was made on circumstantial evidence, a procedure that is subject to severe criticism when in this day the facilities for laboratory confirmation are available to almost all physicians. It is true that the earlier a chancre is recognized and the proper treatment is instituted the better are the results from treatment.

This does not mean however, that a diagnosis of acute syphilis should be made on a hunch or the mere fact that a lesion was observed on the penis. The difference in the results from treating a chancre three days old and one a week old are not great enough to hazard such a diagnosis and subject a patient to a course of unnecessary treatment on such slim evidence. Neither is the fact that the consort was known to have early syphilis sufficient reason for instituting treatment in this man, because it is not uncommon for syphilologists to see individuals who have been exposed to persons with acute syphilis and who have had willy-nilly prophylaxis not acquire the infection. It is the practice of some physicians in situations such as this to return the patient to the doctor who made the original diagnosis and have him continue as he sees fit the basis for this procedure is that the second physician while he

is not able to confirm the diagnosis, neither is now able to refute the fact that the patient may have had a chancre.

The evidence presented by the inquirer would indicate that a chancre was not present, because although possible it is not probable that the small amount of treatment given the patient would prevent the Wassermann reaction from becoming positive by this time. One of two procedures may be adopted either continue observing the patient weekly and taking a Wassermann test once a week for the next two months and then once a month for six more months, or continue treating him for acute syphilis by the use of a continuous system of treatment with arsphenamine and a bismuth compound. It would seem that the first course is the one indicated.

THIRD GENERATION SYPHILIS

To the Editor—In a family with syphilis there are cases of congenital syphilis even in the third generation inherited from the mother who also has congenital syphilis. The husbands of two of the girls with congenital syphilis have negative blood tests and no history of ever having had syphilis. I understand that a man cannot contract syphilis from a woman that has congenital syphilis. Is this correct? Syphilis was first acquired by the father with a penile chancre three years before marriage, the history of the sore being obtained from him a few days before he died at the age of 60 from coronary thrombosis and syphilitic aortitis. He never realized that he had syphilis and never had been treated. His wife is now 56 years of age and has hypertension of 250/130 and has had two severe attacks of acute pulmonary edema that required phlebotomy. There is no other evidence of cardiovascular syphilis or involvement of the central nervous system. She and her husband both gave two positive Hinton and Wassermann tests on their blood. The mother's first pregnancy terminated in an apparently normal full term girl now 28 years of age with no signs or symptoms of syphilis except positive blood tests. She also has pulmonary tuberculosis and has two girls aged 9 and 7 years who also have positive blood tests but are apparently normal children except that the 9 year old girl has Hutchinson's teeth. The mother of these two had only two pregnancies. The second pregnancy of the original mother was terminated with an apparently normal full term child now 27 years of age and she has a boy 8 years of age resulting from her first and only pregnancy. The boy is apparently in good health but he and his mother both have positive blood tests. This mother also is in good health. The third, fourth, fifth and sixth children of the original mother all have negative blood tests and none of them show any clinical evidence of syphilis. One of these girls has had an apparently normal full term baby with negative cord blood. The original mother did have an abortion between the third and fourth children and one between the fifth and sixth but never had a miscarriage or stillborn or premature birth and as said before never received any treatment. In fact do one in the entire family know that syphilis existed and consequently none had ever received any treatment. I have not done any spinal punctures yet nor any bone or heart and aorta roentgenograms. None have any signs or symptoms of clinical syphilis except one 9 year old girl as previously mentioned with Hutchinson's teeth and the original mother with acquired syphilis having hypertension and subject to attacks of acute pulmonary edema. The questions I am most interested in are: Whom should I do spinal punctures on and what x-ray examinations are necessary? Should spinal punctures be done on those with negative blood and how many negative blood tests should one get to rule out congenital syphilis? Is it likely that any of the girls with negative blood might later have a child with congenital syphilis? Is it usual or unusual for the first mother to have had no miscarriages but for the first three pregnancies to be full term, the first two with positive blood and the other four children to have negative blood even though the mother was never treated? I expect to do spinal punctures on the first two grown daughters with congenital syphilis and if the fluid is negative should they receive any treatment and if so please outline the treatment remembering that one has pulmonary tuberculosis which is at the present fairly well arrested. I have been told that if a patient with congenital syphilis goes beyond the age of puberty without any signs or symptoms of the disease treatment is not necessary. What treatment should the three young children in the third generation receive? It will be rather difficult to give neocarsphenamine as they will probably not be very cooperative. What is the consensus by well recognized authorities on the use of stovarsol in such cases? Should the original mother with hyper-tension receive any treatment? MD New Hampshire

ANSWER.—Third generation syphilis may occur but is exceedingly difficult to establish with certainty. It is relatively infrequent. Among 171 children born to eighty-eight congenitally syphilitic mothers in one large syphilis clinic of the country, only eight of the infants themselves had syphilis. This is of course far below the expected incidence of infantile infection in children born of mothers with acquired syphilis.

In the family under discussion the fact that the first and second children of the original couple have positive Wassermann reactions and have themselves given birth to congenitally syphilitic infants is not proof of the existence of congenital syphilis in the second of the three generations. In order to establish congenital syphilis in the second generation, signs or congenital infection should be present in addition to the

positive serologic observations. In their absence one cannot rule out the possibility of an acquired infection in the two women of the second generation.

It is true that a man cannot contract syphilis from an adult congenitally syphilitic woman.

Spinal fluid examinations should be done on the two syphilitic mothers of the second generation and on the three syphilitic children of the third generation. In the absence of physical signs suggesting neurosyphilis, it is not necessary to do spinal fluid tests on any of the seronegative members of this family. It is unwise to examine the spinal fluid in the grandmother, whose cardiovascular condition is not due to syphilis and is sufficiently grave as to be the most important element in the picture.

X-ray examinations of the cardiovascular stripe might profitably be done in the grandmother and in the two mothers of the second generation. They are not necessary in the children of the third generation, since the heart and aorta are practically never involved in congenital syphilis.

It is highly improbable that any of the girls of the second generation with negative blood tests will subsequently have syphilitic children unless they themselves acquire syphilis before the babies are born.

It is not unusual for the sequence of pregnancies to have occurred as in the original mother without miscarriages or stillbirths with the early children syphilitic and the later children normal. Kassowitz's law is to the effect that the virulence of syphilis for the child decreases with the duration of infection in the mother and that after the lapse of a sufficient time interval, usually fifteen to twenty years, a syphilitic woman may bear normal children.

It is not true that, if a case of congenital syphilis goes beyond the age of puberty without signs or symptoms, treatment is unnecessary. On the contrary congenital syphilis remains completely latent much less frequently than the acquired infection, and any congenitally syphilitic person should be treated regardless of the age at which his infection is discovered.

The original mother with hypertensive heart disease had probably better not receive any antisyphilitic treatment, in view of the gravity of her nonsyphilitic heart condition.

The older daughter of the second generation with pulmonary tuberculosis should be treated by the methods outlined by Padgett and Moore in the *American Review of Tuberculosis* (33 10 [Jan.] 1936).

The next daughter of the second generation should be treated in accordance with the principles outlined in chapter 17 of Moore's monograph "The Modern Treatment of Syphilis," Springfield, Ill. C. C. Thomas 1933.

The three young children of the third generation should be treated in accordance with the principles outlined in chapter 28 of Moore's monograph. Sulfarsphenamine may be used in place of neosarsphenamine.

The use of acetarsone (stovarsol) by mouth in any form of syphilitic infection, congenital or otherwise, is distinctly in an experimental stage and is not to be advised for general use.

LOCAL ANESTHETICS

To the Editor—I am interested in securing data on local anesthetics of prolonged action. I am interested particularly in securing anesthesia of twenty four hours or longer. What is the duration of anesthesia of anesthetic, and quinine and urea?

M D Massachusetts

ANSWER—Ever since the introduction of procaine hydrochloride for anesthesia by infiltration and nerve block, attempts have been made to prolong its prompt but evanescent action. Epinephrine in 1:1000 solution, 3 drops to the ounce of 1 per cent procaine solution, prolongs the anesthesia of an intradermal wheal from fifteen minutes to over two hours. It has been shown that the higher the concentration of the free base of the local anesthetic, the more rapid and prolonged will be the action as only the procaine base penetrates into the nerves. The recognition of this principle resulted in the preparation of borates, bicarbonates and phosphates of procaine instead of the hydrochloride in order to increase alkalinity and increase hydrolytic dissociation of the procaine. In practice, especially in anesthesia by infiltration no appreciable difference could be noted between the chlorides and the weaker acids but in blocking nerve trunks there seemed to be a small but definite prolongation of anesthesia when using the procaine in a buffered solution.

Quinine and its derivatives, isoamylhydrocupreine (eucupin) and nupercaine have been advocated to prolong the duration of local anesthesia. Quinine and urea hydrochloride in from 0.5 to 1 per cent solution has been especially used for rectal work, and for tonsillectomies to alleviate postoperative pain. A 2

grain (0.13 Gm) tablet may be dissolved in an ounce (30 cc.) of water, making approximately an 0.8 per cent solution. When used by interdermal infiltration the anesthesia may last a week. It produces, however, a definite damage to the tissues, may result in long lasting indurations and, if not used sparingly in sloughing. The same may be said to a lesser degree of isoamylhydrocupreine (eucupin), which was used in 1:1,000 concentration. Both these drugs have been superseded by nupercaine, which if used in dilutions above 1:500 does not seem to irritate the tissues. Its toxicity, however, is greater than that of cocaine and its use is gradually diminishing except as a surface anesthetic in certain special fields, as ophthalmology and urology.

Pantocain, a cocaine derivative, produces in 1:1,000 concentration an anesthesia which is approximately of double duration as compared with that of procaine. Its value lies especially in spinal anesthesia, if an anesthesia of over one hour to an hour and a half is required.

There are a number of other local anesthetics appearing on the market. In estimating their value it is safe to say that the prolongation of the anesthesia produced by procaine is justifiable only to ensure a painless operation of longer than the average duration. As tempting as it is to alleviate postoperative pain by local anesthetics any drug that produces a twenty-four hour anesthesia or analgesia must seriously depress protoplasmic activity, interfere with the healing of wounds or produce degeneration in the peripheral nerves or roots. The alleviation of postoperative pain by general sedatives, analgesics and hypnotics seems safer at present than the production of a local analgesia of long duration.

INTERMITTENT TREATMENT OF SYPHILIS IN RURAL AREAS

To the Editor—In isolated sections it is often difficult to give weekly injections of neosarsphenamine. In some cases this would require over 100 miles in travel to come for treatment. In winter time even patients nearer by are often blocked with snow drifts. What kind of results would you expect if only one or two injections of arsenic or the heavy metals were given each month if treatment by mouth was continuous and what drugs by mouth would you advise? Many of these patients will not take the trouble of mercury injections and bath tubs are usually not available. In case Wassermann and Kolmer tests are negative but the Kline test is positive does that account an official diagnosis of syphilis? I have seen the wife give a four plus Wassermann reaction but the husband only a two plus Kline with other tests negative. How would you weigh the balance between intermittent treatment of syphilis and none at all? Some of the people who need treatment must rove about a great deal and are hard to find. I carry sterile syringes around with me and like to give treatment whenever I find them trying to persuade them to take regular treatment by mouth if regular injections are not possible. Will you kindly advise on these problems? About two years or more ago in *Queries and Minor Notes* you rated the possible percentage of syphilis that was negative on all serologic tests as approaching one third as I remember it. How would you sum up our present knowledge of this point now? Please omit name and locality.

M D

ANSWER—Treatment for syphilis is conditioned not alone by the drugs used and by their mode and route of administration but by the stage of the disease, the type of involvement and the reactions of the patient. It is definitely dangerous and disadvantageous in a considerable proportion of cases to give the arsphenamine group of arsenicals in inadequate dosage or at long intervals, especially in early syphilis. A monthly injection of neosarsphenamine intravenously would therefore be as likely to result in trouble for the individual and relapse in infectiousness for the population contacts at large as any procedure that could be followed. In circumstances such as the correspondent describes in which injections of an arsenical can be given once a month it would not be unreasonable or impossible, provided the patients are cooperative, to revive the old method of intramuscular administration of arsphenamine long used by Richard L. Sutton of Kansas City in his practice and described in several of the earlier editions of his *Textbook of Dermatology* and quoted by Stokes (*Modern Clinical Syphilology*, ed. 1, Philadelphia, W. B. Saunders Company 1926 p. 200). While this method is somewhat painful and lays the patient up for perhaps a day, the discomfort is to some extent controllable, and the intramuscular administration of arsphenamine has always had a deserved respect. Such a procedure as this is not advocated for the use of any arsphenamine intravenously or for the more rapidly absorbed and eliminated arsphenamine modifications such as sulfarsphenamine and neosarsphenamine intramuscularly as they do not establish significant absorption deposits.

There can be no substitute for mercurial injections for patients who are frozen in. If the clean injection technique of

Cole and his associates is employed, the use of the bath tub becomes relatively unnecessary and the dosage can be adjusted by a little experience, so that with even an approach to reasonable mouth hygiene, salivation can be prevented even in long inunction courses. Washing the mouth twice daily with 30 cc. of water to which has been added a few drops of a mixture of one part tincture of kino and two parts tincture of myrrh will assist materially in keeping the gums in good condition, and the solution can be painted full strength on the gums when this seems desirable. The essence of the clean inunction consists in a full thirty minutes of rubbing in of the ointment over the chosen sites, followed by cleansing the skin with benzene or naphtha, or even a quick sponging with a good grade of gasoline. A good sweat in blankets can be taken weekly. It has also been shown that it is possible to give an inunction over the entire body once a week and secure adequate mercurialization in this way. A belt or girdle on which ointment is smeared has been used by the U S Public Health Service. From every standpoint, this is one of the safest forms of treatment known. It must be understood, however, that mercury does not control infectiousness and that bismuth compounds are relatively less effective than an arsphenamine. Probably the best combination under difficult circumstances would be rather large doses of potassium bismuth tartrate in oil suspension, alternating with arsphenamine intramuscularly as suggested.

It should be clearly understood that mercury by mouth, whether intermittently or continuously given, is of no value so far as curative effects or control of infectiousness is concerned, in the overwhelming majority of cases of early syphilis. It is likewise relatively ineffective in the later complications of the disease and of no use whatever in syphilis of the nervous system.

The question as to whether a positive Kline test with a negative Kolmer or other form of Wassermann test can establish the diagnosis of syphilis must be considered on the merits of the individual case, taken as a clinical whole. In general, however, it may be said that a properly performed Kahn test has an exceedingly small margin of error and should be taken very seriously. In all cases it is desirable to repeat a positive serologic test by whatever technic, for confirmation purposes.

The intermittent treatment of syphilis, while less effective than continuous treatment, especially in the early phases of the disease and in early latency, cannot be rated as wholly ineffective. There are a number of aspects of the disease in which it is the desirable form of treatment, including late latency and late manifestations of various kinds, including visceral and cardiovascular syphilis and late tabetic neurosyphilis. For the proper interpretation of considerations of this sort, the study of one of the standard textbooks is advised. The correspondent is recommended to the division of venereal diseases of his state board of health, if there is one, for cooperation which can be furnished by traveling therapists, who in highly organized state venereal disease services can do much to make treatment available to relatively isolated persons and communities.

The estimation of one third of all syphilis as negative to all serologic tests is certainly too high for the present highly sensitive and highly specific procedures such as the Kahn, Kline and Kolmer-Wassermann tests. The proportion of positives obtained should range from very close to 100 per cent in florid secondary syphilis and dementia paralytica to perhaps 78 to 85 per cent in some aspects of cardiovascular and late neurosyphilis or neurosyphilis characterized by highly localized lesions.

POOLED HUMAN CONVALESCENT SERUM FOR POLIOMYELITIS

To the Editor—Will you kindly advise me if the serum mentioned in your editorial on Serum Treatment of Acute Poliomyelitis is commercially available and, if so, where? Would you repeat the intraspinal dose if so, how often?

SAM J. HOOPER, M.D. Jackson, Miss.

ANSWER—The serum mentioned is pooled human convalescent serum. This preparation is available only through serum centers established by private donations and through municipal and state health departments. We are not aware of an available source in the South but would suggest that the correspondent direct an inquiry to the state health department. In the state of Illinois such serum is furnished gratis under the auspices of the state department of public health and by the Samuel Deutsch Serum Center at the Michael Reese Hospital. There are other sources available in other state and municipal health departments in the Middle West, in the East and in California.

The dose of pooled convalescent human serum recommended at present is from 10 to 20 cc given intraspinally and 100 cc. intravenously at the time of diagnosis. The former amount is

given at the time of the diagnostic spinal puncture. In the event that further serum is needed, an additional 100 cc. is given intravenously from ten to twenty-four hours later. In instances of acute bulbar poliomyelitis, the dosage recommended is 200 cc intravenously and from 10 to 20 cc intraspinally. The latter type is a fulminating disease carrying a high mortality, said to be from 70 to 90 per cent without treatment. There are indications that the mortality is affected favorably by convalescent human serum, but the results are not as striking or gratifying as in the spinal types of the disease.

In the event that there is no serum at present available in the correspondent's locality, any laboratory approved for the manufacture of serum by the United States Public Health Service would be equipped to prepare such a product.

TREATMENT OF LATENT SYPHILIS

To the Editor—A woman aged 23, has been under treatment eighteen months for latent syphilis. At the age of 16 she had a nervous breakdown. It was discovered that the Wassermann reaction was 4 plus. She was then given treatment for a short while. At the age of 22 the Wassermann reaction was 4 plus and the Kahn reaction 4 plus. Jan. 17 1935 I first saw her and gave her weekly injections of 0.45 Gm. of neoarsphenamine for a period of six weeks. February 28 I gave her weekly injections of bismuth subsalicylate 2 grains (0.13 Gm.) for six weeks. April 16 neoarsphenamine 0.45 Gm. for six weeks weekly. May 18 bismuth subsalicylate 0.13 Gm. weekly for six weeks. June 29 neoarsphenamine 0.45 Gm. weekly for six weeks. August 15 bismuth subsalicylate 0.13 Gm. weekly for six weeks. October 10 neoarsphenamine 0.45 Gm. weekly for six weeks. December 4, bismuth subsalicylate 0.13 Gm. weekly for six weeks. Jan. 16 1936, neoarsphenamine 0.45 Gm. weekly for six weeks. March 6 bismuth subsalicylate 0.13 Gm. weekly for six weeks. April 1 a spinal tap was negative for syphilis. April 21 weekly injections of neoarsphenamine 0.45 Gm. for six weeks. June 8 bismuth subsalicylate 0.13 Gm. weekly for six weeks. I should like to know what your opinion is as to whether this young girl should marry or not. Her plans are to do so but she first consulted me as to my opinion. Also advise as to whether I should continue treatment.

A. A. LICHTBLAU, M.D. Canton, Ohio

ANSWER—It is not easy to answer this query as there is insufficient information. No mention has been made of following Wassermann tests on the blood to note the response of the patient to treatment. Moreover, no mention is made of physical examination and its results. This would have quite a lot of bearing on the case, especially if one was to find an aortitis, which is quite often the sequel of an untreated case of syphilis of this type. If careful physical examination shows no evidence of syphilis in the presence of a negative spinal fluid, there should really be no reason why the patient should not get married.

It probably would be well for her to continue the alternating treatment of six injections of neoarsphenamine and six injections of bismuth subsalicylate that she is now on up to a full two years, provided she stands the treatment satisfactorily and she should be given eight intramuscular injections of a bismuth compound every six months for the following two years.

In case she becomes pregnant, since there is danger of passing a latent infection of this type on to the fetus, even when there is no danger of anybody else contracting the disease, it would be well to give her vigorous treatment throughout the pregnancy, consisting of the continuous form of treatment beginning with a course of arsenicals, followed with a course of bismuth and ending with a course of arsenicals.

Naturally a patient of this type should be kept under observation and have a routine physical examination every year the same as is being advocated for every one, and along with this careful check on the cardiovascular system and a blood Wassermann and precipitation test.

SYPHILIS IN INFANCY

To the Editor—A multipara delivered a baby six months ago. The Wassermann report on her at the time was 4 plus. The report on the baby from blood taken from the heel was 4 plus. A report taken by another doctor now is negative without any treatment since birth. Which report should be believed? Do syphilitic babies ever develop an immunity as indicated by these tests? Please omit name. M.D. Washington.

ANSWER—Wassermann positive blood of a mother may be transmitted through the placenta to the infant so that blood taken from the infant shortly after birth may be Wassermann positive while the infant need not be syphilitic. Such a Wassermann reaction may become negative not because the infant develops a spontaneous immunity but because the antibodies derived from the mother disappear. It would be well though, to recheck the baby's blood by Wassermann and flocculation tests.

HAZARDS OF DYE INDUSTRY

To the Editor—A man, aged 30 recently had mild symptoms of gastro-enteritis. He has been working for the past year in a dyeing plant. The dyes used are serbian black B silk brown A pontamine sky blue F F pontamine green B \ pontamine pink G (manufactured by Dupont) pontamine violet B pontamine yellow W B F scarlet 4 B S W and cyanine C R (manufactured by Sandoz). Would any of these dyes be harmful to health on inhalation? The air in the room is heavily laden with the dyes and no ventilating fans are used. Please omit name.

M D New York

ANSWER—Generally speaking coal tar dyes freed from raw material and intermediates may be said to hold little prospect of injury for the dye worker. A few exceptions are to be recognized, such as skin disease from many dyes, damage to the cornea from certain dyes such as methyl violet, and bladder tumors, from a group of dyes including benzopurpurine and benzidine. It is somewhat unlikely that in a dye house any large quantity of the dye would reach the atmosphere. While coal tar dyes may be regarded as only rarely responsible for systemic diseases, the operation of dyeing may provide many hazards. Apart from specific skin disease, the occupational diseases associated with dyeing largely are from mixed intoxicants. Dusts may arise from the fabric being prepared for dyeing. Various bleaching agents may be in use, including sulfuric acid, alkalis, sodium chloride and chlorinated lime. Various mordants may prove to be more toxic than the dyes themselves. The dye solution may be associated with various alcohols, acids and alkalis. More often than not, steam is present in the dye room, thus introducing the hazard both of high temperatures and of high humidity. In certain types of dyeing, especially dyeing by printing, a variety of glues, caseins and glutens may be utilized. Dyeing is at times imperfect calling for the removal of stains, the stripping of the dye and the cleaning of the fabric. This may lead to the introduction of a variety of toxic agents including carbon tetrachloride, trichloroethylene, naphtha, benzene and hydrofluoric acid. Drying and ironing are irregularly associated with dyeing but when present contribute to high temperatures frequently found in dye houses. Prior to the dyeing of some silk fabrics, lead compounds may be introduced for weighing purposes.

Dye workers are prone to suffer from digestive disturbances, arthritides and respiratory disturbances and if fatigue may be regarded as a disease this disease may stand at the top of the list. By and large high temperatures, high humidities, wetness and nauseating odors furnish a greater number of disorders among workers in the dyeing industry than (with the exception of skin disorders) may be traced to the action of specific dyes. The mention in this query of a dye worker suffering from 'mild symptoms of gastro-enteritis' is not a rarity. To the contrary, in some dye houses most of the exposed workers are from time to time so afflicted.

HAY FEVER

To the Editor—I have a patient who suffers from hay fever (rag weed) every fall. The usual serum treatment has not been very effective. Last fall she was given one injection which as she says made her terribly sick for a day and a half and then all her symptoms were gone. What was the substance used and what is the theory of treatment? Would artificial fever do this? Kindly omit name.

M D Ontario

ANSWER—The relief given in this case may have been due to the fact that the injection was given near the end of the season when the symptoms would normally disappear. Or a foreign protein may have been given in a large enough dose to cause a constitutional reaction. This sometimes produces relief. Artificial fever has not been found useful in the treatment of pollinosis.

BLOOD SUGAR LEVELS

To the Editor—In THE JOURNAL Aug 17 1935 there is an article on page 484 entitled Hyperglycemia. In reading this article one gets the impression that the normal blood sugar should be from 100 to 140 mg per hundred cubic centimeters of blood. Does this mean on a fasting diet? My impression has been that the normal sugar level on a fasting diet should be between 60 and 120 mg. I would appreciate your explanation of this article which is quite confusing. What is the consensus at present with regard to the highest blood sugar that would be considered within normal limits? Please omit name.

M D New York

ANSWER—The blood sugar levels on fasting should be between 100 and 120 mg per hundred cubic centimeters of blood, and after meals no higher than 140 mg. While these are the figures accepted as normal it must be realized that there are many variations from these figures. When the blood sugar is lower than 100 mg it usually indicates that the diet is fairly low in sugar or that there is a tendency at least to a hypo-

glycemia associated with some endocrine disturbance. A blood sugar of 60 mg would certainly be considered in the hypoglycemic range. Higher blood sugars frequently occur in apparently normal individuals, especially persons over 50 years of age.

PAIN IN POLIOMYELITIS

To the Editor—Please describe in THE JOURNAL the types of pain characterizing anterior poliomyelitis. I have seen no adjectives preceding the word pain in any of the references read. If this description is unavailable probably in the near future I shall be able to furnish one from my recent personal attack.

W J OWINGS M D Brent Ala

ANSWER—Pain is not a prominent symptom as a rule, in an early acute attack of poliomyelitis. While headache is common at the onset it is not generally severe as in meningitis. The muscles, however, are hypersensitive. It is for this reason that the average patient resents handling and desires to be left alone. Manipulations of the extremities may cause pain. The 'ventral flexion sign,' which is elicited by bending the head and body forward toward the knees, often results in the patient complaining of sharp pain along the spinal column.

After the acute stage of the disease, contractures of muscles, particularly the flexor groups are the sources of most painful sensations.

In the early stages of poliomyelitis pain not induced artificially is usually described as being dull. Later in the attack, pain attributed to contractures is more lancinating in character.

POLLEN AT MIAMI

To the Editor—I would appreciate it very much if you would let me know what your opinion is with regard to Miami Beach Fla. for hay fever and pollen asthma. For the past few years I have been going north and recently have heard that Miami Beach has a lower pollen count. Do you advise it for pollen asthma? I am a ragweed sufferer beginning August 15. I should like to go to Miami Beach because I take my 10 year old son with me and the sun would do him so much good.

M D

ANSWER—No local pollen record has been published for Miami Beach but atmospheric pollen studies have been made at the weather station in Miami and at a private residence in Coral Gables. A very small amount of ragweed pollen appeared on the slides at Coral Gables but only a trace at Miami. The difference is no doubt due to the fact that the slides at Miami were exposed closer to the shore than those at Coral Gables. Miami Beach is some three miles farther away from the few ragweeds that grow in the truck garden areas.

The total number of pollen grains found at Miami during a whole ragweed season was only eight. The significance of this may be easily appreciated by remembering that in central Indiana the average yearly count is considerably more than 10,000 pollen grains. Nineteen points on the Atlantic and Gulf coast from Eastport, Maine to Tampico, Mexico have been studied by means of atmospheric pollen counts. Of these the Miami station is by far the best.

PHARMACOLOGIC AND THERAPEUTIC PROPERTIES
OF COBRA VENOM

To the Editor—In THE JOURNAL July 11 under Queries and Minor Notes page 153 is printed an Illinois physician's question regarding the use of snake venom in the control of pain as in carcinoma when morphine has lost its control and in controlling hemorrhage as in prostate or bladder hemorrhage.

To me as an experimental investigator devoting a great deal of time and work to the study of the pharmacologic and therapeutic properties of snake venoms the reply seems very inadequate.

The use of snake venom for therapeutic purposes may be sharply divided into three categories. The first is the use of the venom of the moccasin (Ancistrodon) for the control of certain hemorrhagic conditions. Noteworthy work on the subject has been done especially by Dr S M Peck and his collaborators.

In the second category is to be considered the use of crotalin or the venom of the rattlesnake (Crotalus) in the treatment of epilepsy. Both foreign and American writers have published papers on this subject.

Probably the most interesting therapeutic application of snake venom and that concerning which the greatest amount of scientific research has been done is the use of cobra (Naja) venom for the treatment of the severe pains accompanying advanced malignant tumors and some other painful disorders of nonmalignant nature. Most of this work has been done in France at the Pasteur Institute but more recent contributions to the subject are found in German, Spanish and American literature.

Book Notices

Neurological Surgery By Loyal Davis M.S. M.D. Ph.D. Professor of Surgery and Chairman of the Division of Surgery Northwestern University Medical School Chicago. Cloth Price \$6. Pp 429 with 174 illustrations Philadelphia Lea & Febiger 1936

This book is addressed to the general practitioner in order to put him abreast of the modern development of neurologic surgery. The first chapter is therefore interesting as a statement of the amount of knowledge, in the opinion of the author, which will enable one "to group the important signs and symptoms and accurately localize a lesion." One may have this knowledge and much more and still be unable to localize many lesions of the nervous system. Nevertheless the information given is in the main accurate, although many statements are too dogmatic and need qualifying, such as that "atrophy of the muscles does not occur when the limbs are stiff and spastic." The statement that lesions of the ninth cranial nerve cause dysphagia, particularly of solid food, and regurgitation of liquids is not correct, there is no defect of swallowing following complete transection of the glossopharyngeal nerve. The discussion of the cerebellum is inadequate. The author's attitude toward craniocerebral injuries is in accord with the judgment of qualified surgeons but there will be vigorous dissenters. One might expect, in a book designed primarily for nonsurgeons, more specific directions in many places, e.g., the physician is instructed to use less depressant drugs than morphine, but no substitute is named. Much of the discussion of intracranial tumors sounds strangely familiar, even to entire sentences but curiously enough, in contrast to the others this is the only chapter that has no reference to any fundamental article or monograph in its field. Figure 23 does not show well the gross appearance of glioblastoma or figure 24 its microscopic structure. Most neurologic surgeons have tired of futile radical operations on glioblastomas. The author's curt dismissal of roentgen therapy for hypophyseal adenomas will find many dissenters. The statement that "these glandular changes (following operations on a pituitary adenoma) will not interfere with his or her return to an economic and social independence" is unfortunately not always true. Figure 65 looks more like the gliosis surrounding a craniopharyngioma than the tumor itself. The calcification associated with the venous angiomas of epileptic patients having facial nevi has been shown to be in the adjacent gyri and not in the abnormal blood vessels. The treatment of brain abscess is still a subject of much discussion, as the author justly remarks, probably few neurologic surgeons would subscribe to the present method of the author as described on page 171 which must injure seriously the very capsule which the brain has been at so much pains to build up. The discussion of the signs of intracranial extension of an infection might well have been amplified, since this is the important moment for the physician in charge and a valuable guide to the further handling of the case. The treatment of osteomyelitis, cysts and tumors of the skull, while not properly neurologic surgery, tends more and more to gravitate into the hands of neurologic surgeons because of the neurologic complications. Trigeminal neuralgia is discussed with the thoroughness it deserves, its treatment being one of the great triumphs of neurologic surgery. Glossopharyngeal neuralgia is for some reason not discussed in the section on lesions of the last four cranial nerves but is briefly mentioned in the differential diagnosis of trigeminal neuralgia. In the treatment of injuries to the spinal cord the author might well have discussed at some length the relatively safe, simple and effective method of treating fracture-dislocation of the cervical vertebrae by means of suspension with tongs. Most neurologists and neurologic surgeons do not share the author's views of the dangers of using iodized oil for the localization of spinal cord tumors whenever it may be necessary. The value of x-ray evidence of the localization of intraspinal tumors is not sufficiently emphasized. The advice given for the handling of injuries of the peripheral nerves is excellent. The author has obviously profited by his long association with Pollock. He has long been interested in the surgical relief of pain, his investigations in this field are well summarized. The discussion of surgery of the autonomic nervous system is very conservative just as on the whole yet the excellent results of autonomic denervation of the lower extremities in Raynaud's disease might have been

emphasized as were those obtained in megacolon. The author has a healthy skepticism also for the surgical treatment of epilepsy. The so-called cerebellar fits are not epileptic manifestations. Cervical rib, syringomyelia and aneurysm are briefly discussed. After rather pessimistic accounts of hydrocephalus and spina bifida the book ends with a discussion of the problem of chronic arachnoiditis. It is written in a clear and understandable style. One notes the strange expression "physical therapy treatments," which with "radium therapy treatments" and "x-ray therapy treatments" seems to be establishing itself in the medical vocabulary. The author has been somewhat careless in recognizing the source of illustrations, figure 48 is obviously from Cushing. There are very few typographical errors, the typesetter has had some trouble with the word "chromophile" though why it should trouble him more than "chromophobe" is not evident. On the whole the book is well printed, well arranged and well adapted to its purposes. It contains a sane and conservative discussion of the field of neurologic surgery, and the physician who follows its advice will not go far astray.

L'Impuissance sexuelle chez l'homme. Etiologie diagnostique traitement Par M. Palazzoli. Préface du Professeur Legueu. Paper Price 45 francs. Pp 284. Paris. Masson & Co 1935

This is a careful and scientific report of a lifetime spent in studying the physiology and pathology of the male sex function from the libido and mechanical points of view. The author discusses thoroughly the innervation of the male sex organs and shows what nerve centers influence the male sexual function. He shows that erection depends on a cerebral or psychogenic stimulus as well as a local or dermovenous stimulus, the correction being made by the pyramidal tracts to a lumbar center, from which a sacral reflex completes the circuit. A nerve lesion involving any of these structures may produce clinical impotence. Excellent diagrams illustrating the nerve pathways are shown. The act of coitus is discussed under the following nine headings: (1) sexual desire, (2) glandular secretions, (3) erection reflex, psycho, sensory, (4) intromission, (5) erection local stimulus, (6) pleasurable, voluptuous sensations, (7) orgasm, (8) ejaculation, (9) depletion. These headings should be in mind when taking a patient's history, and the exact point of failure determined, also how and when did his inability appear, and has this inability remained constant or become worse? Answers to these questions will give the physician a lead as to the exact special examinations that should be ordered. Diagnosis is discussed under four heads: general bodily state, organic examination as to nervous endocrine glands, venereal infections, general or local, psychic examinations, special examinations: vegetative system and urologic examination. There is an excellent description of the etiologic local lesions involving the prostate, posterior urethra and verumontanum. Treatment is considered under three titles: (1) general medical, (2) local treatment: testicle grafts, vas ligation and urethral local, (3) psychic treatment. These are all considered in minute detail. This work may be unreservedly recommended as a sane, scientific discussion of the subject.

Foundations of Biology By Lorande Loss Woodruff. Professor of Protozoology in Yale University. Fifth edition. Cloth Price \$3.50. Pp 583 with 378 illustrations. New York: Macmillan Company 1936

This standard textbook has been extensively revised by the author to include significant work of the last five years, especially in the field of genetics. The illustrative subjects, with the exception of such figures as 103, 104 and 120, which are excessively schematic, are artistically and truthfully executed. They are so well chosen that by extensive reference in the text they become the common link between the various sections of the book. This fact, plus the remarkably lucid introductory and concluding paragraphs of each chapter keeps the enormous number of items considered correlated in an almost perfect unit, and the student is properly oriented at all times. These paragraphs are worthy of the attention of the most seasoned scientists.

The material presented is sufficiently comprehensive to give the general student a background for understanding himself and his place in the great panorama of living organisms. A brief orientation chapter on the scope of biology is followed by the development of the cell concept (plant and animal),

then the multicellular organisms with increasing complex functional systems, considered largely under the headings of plant and animal bodies (structure), nutrition, respiration, circulation, excretion, reproduction and coordination (nervous system). This takes up one third of the text. The topics of origin and continuity of life, embryology, inheritance, adaptation and origin of species occupy almost another third. The chapters dealing with applied and historical biology are nicely tied into the general theme, but it is in the two chapters dealing with a review of the plant and animal kingdoms that the author reaches the climax of his coordinating ability. Here the student seems to be getting a concentrated course in morphology and comparative zoology, but in reality he is presented with additional material and opportunity, coordinated by cross references, for extensive application of the principles previously acquired. The various theories and hypotheses are not presented with a bias but sympathetically and stimulatingly, so that the student should appreciate the fact that the final story has not yet been told. The bibliography given for each chapter is apparently chosen to give the various points of view on the different topics and to stimulate the capable student to go further afield in his special interests. There is a fine glossary and index. The student who masters the material set forth in this textbook should know how to observe, correlate and think, and thus will be well prepared in biology for medical schools.

Le décollement de la rétine et son traitement. Par F. Terrien professeur de clinique ophtalmologique à la Faculté de médecine de Paris. Prosper Veil ophtalmologiste des hôpitaux de Paris et M. A. Dollfus. Paper. Price 40 francs. Pp 163 with 49 illustrations. Paris: Masson & Cie 1936.

Based on five years' experience in the eye clinic of the Hotel-Dieu, these authors are publishing their impressions of surgery of retinal detachment with the hopes that the more hesitant of their confrères will see fit to operate on this condition early. They have observed more than 200 cases and have used all types of modern operations. In consequence they are in a position to evaluate the various types of surgical procedures in relation to the various types of retinal detachment, taking into consideration the multiple factors of time of duration, etiology, refraction and presence of holes. Their end results agree in the main with those of other large clinics, namely, a reattachment can be secured in from 55 to 70 per cent of the cases, depending on the care in selection of cases for operation. The book is divided into ten chapters, the first five of which deal with the clinical study, etiology and anatomy of detachment. Then comes a long chapter devoted to the various types of modern surgical procedures, written in sufficient detail and well illustrated in black and white. The historical aspect of this is particularly well done. Four chapters are devoted to after-care, pathology and medical treatment. The book has four good colored plates, illustrating various types of holes in the retina. There is no bibliography or index and the literary references are few and far between. The work of the American investigators is absolutely ignored, Clifford Walker is not even mentioned. The book making is the typical French paper-covered affair that falls to pieces during the first reading. The volume is of interest but does not mark any milestone in the rapidly advancing road that will lead to the solution of the problem of retinal detachment.

A Study of Mortality in Cincinnati for the Period 1929-1931. Paper. Price \$1. Pp 187 plus charts. Cincinnati: Public Health Federation 1935.

This volume reproduced in mimeograph and planograph is a comprehensive study of mortality in Cincinnati typifying the way in which mortality ought to be studied everywhere. It is only by delving into the details of a death rate that an intelligent conception can be had of what its most important components consist. In Cincinnati, a city which has always been notable in public health circles for the relatively small part played by the city health department and therefore the correspondingly great importance of voluntary agencies the principal causes of high mortality are found to be appendicitis, enteritis, whooping cough, scarlet fever, automobile accidents and tuberculosis while favorable conditions are manifest in death rates due to diphtheria, influenza, cancer, heart disease, pneumonias,

nephritis, suicide and diabetes. The report brings out the close relationship between low income, poor housing and consequent underprivileged status. With respect to recommendations, the most significant are those calling for reorganization and expansion of public health facilities on a county-wide basis "in order that all forces may be most effectively joined." Especial attention is recommended to families of low income and to the Negro population. Of practically equal significance is the recommendation that preventive and curative health work of tax supported agencies "should be under central direction and should function in close cooperation with the academy of medicine, the college of medicine and other health and social agencies." The report is significant for two reasons: first, it is a dispassionate, thorough and scholarly evaluation of the situation as it exists; second, it is symptomatic of the trend toward cooperation between medical and public health agencies. In this trend many observers see the only logical direction in which preventive and curative medicine can march side by side.

Survey and Appraisal of the Health Activities and Needs of Louisville, Kentucky, November 1935. By Carl E. Buck, Dr. P. H. Field, Director, American Public Health Association. Awarded to the City of Louisville in connection with the 1935 City Health Conservation Contest. Paper. Pp 47. Louisville: Health Council 1935.

This report is another community appraisal, of which there have been many in the last ten years. This particular survey was an award incident to the Interchamber Health Conservation Contest sponsored by the American Public Health Association and the United States Chamber of Commerce. It sets forth the status of public health work in the city of Louisville and makes certain recommendations, of which the most significant is "The Louisville City Health Department must be taken out of politics and kept out of politics." An analysis of the points in the scoring schedule show that Louisville's health program is rated at 737 out of a possible 1,000. This is purely a quantitative measurement and must be accepted with all the reservations which that statement implies. Of particular interest to the medical profession in this connection is that of these points only seven, or 0.9 per cent, were credited to the activities of practicing physicians in Louisville. This would indicate an opportunity for the medical profession to become far more active in preventive medicine. Such an opportunity for greater participation in public health work on the part of the medical profession exists not only in Louisville but everywhere. Community surveys of this character, if they lead to better community cooperation, reflect a significant trend.

The Natural History of Disease. By John A. Ryle, M.A., M.D., F.R.C.P., Regius Professor of Physic in the University of Cambridge. Cloth. Price \$5.25. Pp 438. New York & London: Oxford University Press 1936.

This volume is made up of a collection of thirty-four papers, the majority of which, as the author tells us, have appeared previously in medical journals of the past ten years and are based on addresses to medical societies or clinical lectures given at Guy's Hospital. They are concerned more particularly with symptomatology and the portraiture of disease than with pathologic changes or diagnosis by means of laboratory or instrumental aids. The theme of the book is stated on page 22.

There is no disease of which a fuller or additional description does not remain to be written, there is no symptom as yet adequately explored. It will be noted that this is much the same idea that was so strenuously set forth by Mackenzie, that research ought not to be entrusted entirely to the laboratory worker or the full time hospital man, that the active practitioner has a rich field for investigation in the home and in the ward. In fact this is the text of one of Ryle's best papers, in which he discusses research in clinical medicine taking issue with some of the views that were so forcibly advocated by Sir Thomas Lewis in 1930. The author is somewhat given to philosophizing. At the end of a paper on the natural history of duodenal ulcer he says "It is, I believe, a just criticism of Surgery and Medicine in the present era that they have concentrated on parts to the exclusion of the whole and on technique to the exclusion of philosophy. In duodenal ulcer no less than in many other maladies, we have come to rely upon too narrow a pathology. In our therapeutic quest we have been too little observant of physiological principle. We are

all compelled by the magnitude of our subject to be something of specialists, but this should not necessitate an abandonment of that naturalistic outlook which marked the achievement of our old preceptors from Hippocrates to Hunter." A few subjects selected at random may show the scope of the book: the study of symptoms, anorexia, on examining the rectum, the natural history, prognosis and treatment of staphylococcal fever, of streptococcal fever, of infections with *Bacillus coli*, of angina pectoris and allied seizures, thrombophlebitis migrans. While the author does not write in the attractive style of some other occupants of the royal chairs of medicine in Cambridge and Oxford—the memory of Allbutt and Osler is yet green—the essays based on ample experience, careful observation and, in general, sound reasoning are presented in such a form as to make them pleasant and profitable reading for the occasional hour.

L'artériographie des membres et de l'aorte abdominale. Etude critique
Par Henri Reboul. Préface de Ch. Laubry. Paper. Price 40 francs.
Pp 187 with 82 illustrations. Paris: Masson & Cie 1935.

This is a concise but critical review of the development and status of arteriography. After a historical relation of the development of the method in the first chapter the author considers in successive chapters the contrast substances, the mechanical factors involved in intra arterial injection of the contrast medium, the vasomotor reactions, the incidents and accidents occurring in his own work, the results and the author's therapeutic deductions. The rest of the book is made up of case histories and arteriogram films to illustrate various phases of arteriography and its clinical value. An essentially complete bibliography is included. The book is well printed and the illustrations are excellent, but most to be admired are the lucidity of presentation and the sanity with which the subject is discussed. For the first time the dangers of injecting preparations of thorium as a contrast medium has been accurately presented. This book should interest all those who are interested in arteriography and in vascular pathology.

Post Graduate Surgery. Edited by Rodney Maingot, F.R.C.S. Senior Surgeon to the Royal Waterloo Hospital. With an introduction by The Right Hon. Lord Moynihan of Leeds, K.C.M.G., C.B., M.S. Volume I. Leather. Price \$45 per set of 3 volumes. Pp 1742 with 846 illustrations. New York: D. Appleton Century Company, Inc. 1936.

This is the first volume of a system which promises to be a valuable contribution to surgery. Anesthesia is concisely discussed and the importance of some of the newer anesthetic agents emphasized. In the chapter on the treatment of shock, one gets the impression that blood transfusion is not given the emphasis which it receives in this country. Most of the volume deals with the surgery of the abdomen. Diagnostic measures and medical management are well dealt with in special chapters. The operative technique of the various authors is well presented. A criticism might be that too many obsolete operations are reviewed. The chapter on the colon and rectum are particularly to be commended, especially that dealing with carcinoma of the rectum. The book is extensively illustrated and there is an extensive chapter dealing with the technique of radium treatment.

25 Jahre Kaiser Wilhelm Gesellschaft zur Förderung der Wissenschaften. Band II. Die Naturwissenschaften. Redigiert von Max Hartmann. Cloth. Price 28.00 marks. Pp 433. Berlin: Julius Springer 1936.

This is the second of a series of three volumes published by Max Planck, president of the Kaiser Wilhelm Society for the Advancement of Science, on the occasion of its twenty-fifth anniversary. The volume is devoted to the natural sciences. It gives a survey of the progress in scientific research as far as the contributions of the various branches of the Kaiser Wilhelm Society are concerned. Only the second part of the volume is of a strictly medical interest, for it surveys the contributions of the institutes for biology and cellular physiology, for experimental therapy, for biochemistry, for microbiology, for medical research for the physiology of work, for research on the brain, for psychiatry and for physiologic research. The introductory paper on the philosophy of the natural sciences, by Dr. Max Hartmann, is likewise of considerable interest. Under the heading "philosophy of physics" he discusses such problems as space and time (the theory of relativity), causality,

particularly in its relation to the quantum theory of Planck, and the nature of matter. Under the title "philosophy of biology" he discusses first causality and teleology and then vitalism, particularly the neovitalism of Hans Driesch, which emphasizes the autonomism of living organisms in contradistinction to the mechanistic interpretation of organic life which prevailed in the second half of last century.

Infant Nutrition. A Textbook of Infant Feeding for Students and Practitioners of Medicine. By Williams McKim Merriott, B.S., M.D. Professor of Pediatrics, Washington University School of Medicine, St. Louis. Second edition. Cloth. Price \$4.50. Pp 431 with 27 illustrations. St. Louis: C. V. Mosby Company 1935.

The first edition of this book appeared about five years ago and was favorably received by both students and practitioners of medicine. The material presented was of special interest because of the author's reputation as a pediatrician and to a greater extent because of his contributions to this particular branch of pediatrics. This new edition should prove equally satisfactory to those interested in the latest concepts of the much discussed subject of infant nutrition. The chapter on vitamins, which was entirely adequate five years ago, has required extensive revision. The new chapter on allergy is not as well developed as most of the other chapters, but there is careful discussion of the various preparations and procedures for feeding the allergic infant. The author writes tersely without affecting the continuity, and the subject matter is well grouped and meticulously indexed. This edition has been made briefer than the preceding one by avoiding repetition and omitting some of the extraneous material. It should prove useful to the physician confronted with the everyday problems of infant nutrition and serve as a standard for the evaluation of the various newer methods of feeding infants.

La radiographie en ophtalmologie. Atlas clinique. Par Edward Hartmann, ophtalmologiste des hôpitaux de Paris. Rapport présenté à la Société française d'ophtalmologie (le 12 Mai 1936). Cloth. Pp 272 with 391 illustrations. Paris: Masson & Cie 1936.

This is one of the publications sponsored by the French Society of Ophthalmology, of which, so far, eight have appeared. It is a fine piece of work, dedicated to the memory of Victor Morax. The book deals with the application of radiography in ophthalmology and really belongs more in the library of the radiographer than in the library of the ophthalmologist. The various chapters take up in order (1) positions for photography, (2) radiography in disorders of the eyeball, with particular emphasis on localization of intra-ocular foreign bodies, (3) radiography in disorders of the orbit, (4) radiography of the optic canal, (5) radiography of the lacrimal passages, (6) radiography of the nasal accessory sinuses, (7) dental radiography (very skimpy), (8) radiography in disorders of the petrous apex, (9) radiography of intracranial tumors, (10) radiography in different diseases of the bones of the cranium and face, (11) radiography in anatomic and physiologic research, 12 and 13 are two short purely technical chapters. A complete bibliography precedes the final table of contents. Naturally, such a book must be illustrated extensively, particularly with reproductions of roentgenograms, the majority of which are well done. Undoubtedly many have been retouched for the sake of clearness, which is perfectly justifiable in an atlas. Photographs illustrating the various positions for radiography are numerous and well taken as are the illustrations of the different types of apparatus. The book making is good and the whole project is creditable.

Clínica quirúrgica. Por Pablo L. Mirizzi, profesor titular de clínica quirúrgica de la Facultad de medicina de Córdoba. Tomo IV. Paper. Pp 425 with illustrations. Córdoba: Librería "El Alcega" 1934.

With the publication of the fourth volume of "Clinical Surgery," Mirizzi completes the work which he has dedicated to Prof. Pedro Vella, his teacher. The first chapter is devoted to the discussion of shock. In the treatment of traumatic shock, Mirizzi recommends that hemorrhages be stopped and that the patient be kept warm and given repeated small doses of morphine. Adequate preoperative management is helpful in the prevention of surgical shock. The selection of an anesthetic is important. Mirizzi states that the administration of epinephrine and blood transfusion is the preferred treatment for surgical shock. Many pathologic processes of organs in

the peritoneal cavity which require surgical intervention are considered. The ordinary surgical conditions are presented as separate chapters, and each chapter has an appended bibliography. This book, together with the first three volumes, may be used profitably by the surgeon as well as the general practitioner. The paper is of good quality and the illustrations are commendable.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Change in Statute of Limitations Not Retroactive—This case came before the Supreme Judicial Court of Maine on an agreed statement of facts. The defendant, a physician, performed a hemorrhoidectomy on the plaintiff, Nov. 18, 1929, and rendered the necessary postoperative care until the following January. It was agreed that the acts and omissions of alleged malpractice occurred between the dates named. Approximately five and one-half years thereafter the plaintiff sued the defendant for malpractice. The statute of limitations in force when the malpractice was alleged to have occurred barred the maintenance of actions for malpractice if not commenced within six years after the cause of action accrued. On March 20, 1931 however, by amendment to the existing law, the time allowed for the commencement of actions for malpractice was reduced from six to two years. The defendant contended that the two year limitation should apply to the present case.

The legislature has full power and authority, said the Supreme Judicial Court, to regulate and change the form of remedies in actions if no vested rights are impaired or personal liabilities created. There is no constitutional inhibition against the enactment of retroactive legislation which affects remedies only. Statutes of limitation fall within this rule. They are laws of process, and, where they do not extinguish the right itself, are deemed to operate only on the remedy. It does not follow, however, that, because the legislature possessed the power to enact a retroactive statute of limitations, it did so in the passage of the amendment under consideration. The language of that amendment makes no reference to causes of action which had already accrued. Barren of such reference the limitation cannot be deemed to have been intended to be retroactive, under the rule of statutory construction that all statutes will be considered to have a prospective operation only unless the legislative intent to the contrary is clearly expressed or necessarily implied from the language used. The court therefore held that the six year statute of limitations was applicable and remanded the case to the superior court for trial.—*Miller v Fallon (Maine)*, 183 A 416

Malpractice Action Based on Tort, Not Contract—The plaintiff was an employee of the Atchison, Topeka & Santa Fe Railroad Company and for a number of years had been a member of the hospital association operated by the railroad company. By virtue of this membership he was entitled to surgical treatment at the association hospital. The defendant, a physician was a member of the hospital association's staff. The plaintiff, suffering from a hernia was operated on by the defendant at the association hospital Oct 23 1930. Alleging that by reason of the defendant's failure to perform the operation in a manner in accordance with the custom and practice of good and prudent surgery, his health was permanently injured the plaintiff sued the defendant April 28 1933. The defendant demurred to the petition on the ground that the cause of action was barred by the two year statute of limitations. The trial court sustained the demurrer and the plaintiff appealed to the Supreme Court of Kansas contending apparently that the statute of limitations applicable to actions based on contracts should control in the present case.

The petition alleged that the defendant orally agreed to perform the operation in accordance with the practice of good and prudent surgery. It will be observed said the Supreme Court that the plaintiff as a member of the railroad company

hospital association was entitled to treatment at the hospital without any new, express or independent contract with anybody. He was invalided to the hospital and there consulted the defendant, a member of the hospital staff. The petition, observed the court, does not allege that the plaintiff paid or agreed to pay the defendant anything for his services. The dues which he had already paid to the hospital association secured to him the defendant's services as a member of the hospital staff. The contract which the plaintiff says he made with the defendant was a contract to perform an operation according to good surgical practice, a method which the defendant, as a surgeon, was obliged to follow in any event, without any contract. The damages which the plaintiff suffered by reason of the operation the court said, were characteristically such as flow from malpractice and notwithstanding the form given to the petition, the gravamen of the action was malpractice, which is a tort. The action was therefore barred by the two year statute of limitations. The judgment of the district court, sustaining the demurrer to the petition, was affirmed.—*Trans v Bischoff (Kan)*, 54 P (2d) 955

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama Medical Association Journal, Montgomery

5: 405-440 (June) 1936

Appendicitis in Infancy and the Younger Group of Children. E. W. Peterson. New York.—p. 405.

Ocular Tuberculosis. E. C. Ellett. Memphis. Tenn.—p. 410.

*Use of Cardiac Stimulants in Acute Infectious Diseases. G. R. Smith. Ozark.—p. 415.

Enuresis in Children. Its Cause and Treatment. J. W. Bogges Jr. Guntersville.—p. 417.

Cardiac Stimulants in Infectious Diseases.—Smith points out that physiologists claim that the cause of death in infectious processes is a condition, akin to shock, in which there is great capillary dilatation with stagnation of the blood in the dilated vessels. This dilatation is produced by the liberation of certain histamine-like substances in the blood stream by the bacteria themselves. If the pathologic changes found in the majority of these cases do not warrant the assumption of an antemortem diagnosis of myocardial degeneration, cardiac stimulants must have been misused in trying to stimulate a heart that did not require stimulating. Recently the pendulum has been swinging toward smaller doses in acute infectious diseases rather than the rapid digitalization method. Whether this is more beneficial or merely less harmful than the larger doses is an interesting question. If there is no evidence of actual myocardial damage and no preexisting heart disease, digitalis is certainly not indicated and may be decidedly harmful if given. The use of cardiac stimulants, then, should be supplanted by the more logical procedure of how best to restore the venous return to the heart or what measures to adopt to increase the blood volume. It would seem that the intravenous administration of isotonic fluids or of dextrose would be a simple and ideal procedure. But owing to the increased capillary permeability present in these cases, the fluid is soon lost in the tissues. Not quite so simple but far more efficacious to increase the blood volume and prevent transudation of fluid into the tissues is blood transfusion. Epinephrine is very useful in some cases of sudden collapse. It is a powerful capillary constrictor, but the effect is too transient to make it dependable. Pitressin has the same effect, although it acts directly on the heart muscle and has a more prolonged action than epinephrine. Strychnine has the effect of lessening capillary permeability and increasing the blood volume. It should be given in larger doses than generally recommended and is much safer than digitalis in general use. Oxygen is useful to relieve cyanosis and lowers temperature but is of doubtful value otherwise.

Improved High Voltage Roentgen Ray Tube. B. Cassen and K. E. Corrigan, Detroit.—p. 818.

The Middle Lobe of the Right Lung.—Hampton and King pay particular attention to the right lateral view of the chest. They hope that their work may aid in the interpretation of certain shadows seen in the lower portion of the right side of the chest which are now commonly and vaguely termed right perihilar thickening, peribronchial fibrosis, right hilar tuberculosis, pleuropericardial disease, thickened interlobar pleura, pleurisy at the anterior costophrenic angle with interlobar extension, increase in lung markings, diminished radiance, mottled dulness, and, most commonly, interlobar effusion. They give a brief anatomic description of the normal lung and of some of the more common shadows cast by disease in the middle lobe, with shadows simulating encapsulated interlobar empyema emphasize some points in differential diagnosis and discuss some of the more unusual shadows cast by a fibrosed or collapsed middle lobe and the effect of pleural adhesions on the shape of these shadows. In the lateral projections of the chest, consolidation of the lateral aspect of the middle lobe casts a triangular shadow, whereas consolidation of the medial portion may cast a rectangular shadow. Consolidation may also produce convexities of the septums of the middle lobe simulating encapsulated fluid under pressure. The fusiform and "overlapping" shadows commonly attributed to interlobar effusion and shadows heretofore interpreted as interlobar effusion are more commonly due to disease within the middle lobe. Interlobar extensions of pleural fluid and thickening of the interlobar septums are not uncommon, but primary encapsulated interlobar empyema in the region of the middle lobe is thought to be rare. Visualization of normal pulmonary septums is common and thickening of the septums is thought to be due to pleural disease. Shadows simulating thickened interlobar pleura are often cast by disease in the middle lobe. That shadows simulating interlobar disease must occupy the normal position of the septums has been observed. The size, shape and position of a contracted middle lobe is markedly influenced not only by surrounding disease but by pleural adhesions. Although certain suppurative diseases of the middle lobe can be diagnosed accurately by roentgen examination alone, the importance of bronchoscopic and iodized oil examinations before surgical procedures is obvious. The secondary and compensatory changes in the thorax resulting from lobar collapse are of extreme importance in roentgen diagnosis.

Fasciography.—Carty's preliminary experience indicates that air injections with resulting fasciagrams have interesting possibilities in the diagnosis of soft tissue tumors and certain types of inflammation of the muscles. They may have a valuable

application in the diagnosis of nerve pain, particularly when there is a question of involvement of the larger nerves. It is an unequaled method for studying soft tissue anatomy, with particular reference to the living anatomy and the study of the intercommunication of fascial planes. There are two dangers that must be studiously avoided: infection and air embolus. Before starting an injection one should exclude diabetes and not attempt the procedure on asthenic individuals. A differential white blood count is made and a relative or absolute polymorphonucleosis is a contraindication. Any suspicion of a pyogenic infection, local or general, is an absolute contraindication. The patient should be specifically told what has been done. Otherwise a false diagnosis of gas gangrene may be made by others. A 50 cc. Luer syringe with a three way stopcock is used. A 3-inch 19 gage needle is attached to the opposite side of the stopcock, leaving the third way free and at right angles. The needle is introduced parallel with the long axis of the part under investigation at a slight angle with the skin. When introducing the needle, firm pressure is used until the superficial fascia is penetrated. This is indicated by a slight "give." While it is possible to do a fasciogram by injecting the air into the subcutaneous space, the procedure is apt to be quite painful and the diffusion of the air is not so complete. When the superficial fascia has been penetrated, the valve is turned so that there is a connection between the needle and the syringe. The plunger is slowly withdrawn until 50 cc. of air is in the syringe, then the valve is turned to connect with the needle and the injection done slowly. The amount of air that can be injected varies according to the part involved. A roentgenogram is made immediately and the position of the air noted. If it is not uniformly diffused or if it is in the wrong locality, there may be a general distribution by massage and further roentgenograms. It is imperative that a soft tissue technic be used, as the average bone technic may obliterate the finer collection of air. The essential principle of such a technic is a high milliampere second and a low kilovolt (peak) ratio. One usually sees immediately after injection in the normal individual a linear collection of air under the superficial fascia in the general neighborhood of the injection. Following massage and manipulation of the part, this localized collection is dissipated and there is a more general distribution. The whole tendency is for the air to assume a linear form without the formation of pockets. In some cases of myositis it has been noted that this linear distribution has been lost, and the air apparently tends to form localized pockets.

Dermatophytosis and Dermatophytids—Wise and Wolf declare that in the United States the majority of vesicular eruptions of the hands in adults exclusive of occupational eczema, dermatitis venenata and eczema of unknown cause are accompanied by fungous infections of the feet. Such eruptions on the hands are usually epidermophytids, monilids or

trichophytids. Owing to the fact that a large proportion of the adult population in this country has or has had fungous infection of the feet, positive reactions to the intradermal and patch tests with trichophytin and oidiomycin are of little significance in their direct bearing on the differential diagnosis of a coincident vesicular eruption on the hands. The significance of focal, local and general reactions following the intradermal injection of extracts of fungi cannot at present be properly appraised with respect to vesicular dermatoses of the hands and feet. The mere fact that a patient has a vesicular eruption on the hands and a coincident eruption on the feet does not indicate that the eruption on the hands is necessarily or presumably an "id" due to dissemination of fungi or their products (or possibly both) from the original focus on the feet. The eruption on the hands may be caused by a number of demonstrable agents other than fungi or it may be evoked by a wholly unknown agent. To differentiate these eruptions, a careful history must be obtained from the patient. The diagnosis of "ids" should not be entertained without strongly corroborative evidence, the most important of which is the demonstration of the causative organism, either microscopically or by culture, from the focus of primary infection of the skin or nails.

Antisiphilic Treatment—Obermayer and Becker try to evaluate the various factors that might be responsible for improvement in the majority of their patients and for lack of improvement in the minority. The general beneficial effect of antisiphilic treatment is caused by the specific effect of anti-siphilic drugs, the nonspecific effect of antisiphilic drugs, the effect of nonspecific treatment and the patient's habits and ways of living. The authors' study was carried out by sending questionnaires to 500 patients chosen at random who were of all ages and in all stages of syphilis and who had been treated for at least one year. Answers were received from about half of this number. It was found that the patient who has had a better regulated life has obtained the best symptomatic improvement. The experiences are in line with the observations of Becker that the results of treatment at the Mayo Clinic, where the patients are hospitalized for one day after the administration of arsphenamine and rest during the remainder of the week, are better than the results obtained in urban practice in which the patients are working and cannot be hospitalized. A physician working in a marine hospital stated that the best therapeutic results he had ever seen were in hospitalized syphilic patients. The ratio between the percentage of patients who gained and the percentage who lost weight is favorable in the patients whose rest was increased during treatment and the normally resting patients, while it reverses sharply in the patients who took no rest. Only 38 per cent of the patients took vacations, but the vacation of the majority of the patients was not spent in relaxation. The data show sufficient beneficial effect of regular and restful living to warrant the statement that the physician who treats syphilis should emphasize to every patient under his care the paramount necessity of rest and relaxation for obtaining the most satisfactory results from antisiphilic treatment. Failure to observe regular hours of rest and to take vacations leads to poorer results from therapy. Life in the large cities has led to overactivity and frustration of the human need for emotional and physical relaxation. Reeducation to a more restful way of living should be part of the task of physicians.

Fixed Arsenical Eruption—Pillsbury gives the following significant observations in his case of fixed arsenical eruption: (1) A fixed macular pigmentation persisted after an exfoliative dermatitis due to silver arspenamine. (2) A livid erythematous urticarial reaction developed gradually and became increasingly severe after successive injections of tryparsamide. (3) Eventually the patient complained of general malaise and drowsiness. (4) Universal sensitivity of the entire skin to arspenamines was evidenced by positive reactions to patch and intradermal tests and (5) there was sensitivity to tryparsamide localized at the sites of the fixed eruption. The reaction to arspenamine was of the eczematous type, superficial and sharply limited to the portion of the skin in direct contact with the allergen. It developed rapidly and started to subside as soon as the patch was removed. The reaction to tryparsamide developed more slowly (in forty-eight hours) and persisted unabated for two days after removal of the patch. It was not superficial and

was distinctly not limited to the site of the contact with tryparsamide, and there was no vesicle formation. It seems entirely possible that the reaction developed as a consequence of absorption of the tryparsamide since the site of shock tissue was principally in the upper portion of the cutis, the superficial portion of the epiderm remaining unaffected by the passage of the drug through it. The reaction of the patient to arsphenamine no doubt belongs to the type of eczematous reactions in which the site of the shock tissue is the epiderm. It seems not improbable that in the original sensitivity to arsphenamine both the epiderm, with its exfoliative dermatitis, and portions of the cutis, with their fixed eruption and pigmentation were the sites of shock tissue and that the gradually developing sensitivity to tryparsamide manifested itself in the portions of the cutis that were previously the shock sites for arsphenamine. The fact that no previously unaffected sites became the seat of the tryparsamide eruption may be another example of the Sanarelli phenomenon as applied to the skin, in which previous sensitization to a heterophile substance leads to reaction at the affected site to a large variety of normally nontoxic substances.

Nevus Vasculosus Accompanied by Streptococcic Bacteremia—Maynard reports a case of gangrene of vascular nevi concomitant with streptococcic bacteremia in which all the angiomatous tissue, even those portions foreign to and having no definite connection with one another, were also immediately involved in the same process. The patient a baby of 9 weeks, was brought for the treatment of two small ulcers, one on the buttock adjacent to the anal opening, the other in the anogenital fold. There was an extensive nevus vasculosis of rather punctate distribution over the entire right leg the entire right buttock and the lower right quadrant of the abdomen. In addition to this there was a large lesion involving the greater part of the dorsum of the right hand. This lesion was raised and unbroken in character. The left side of the body showed no lesions. The lesions were all bright red. The ulcers were painted with Millian's dye and were dressed with bismuth violet ointment. Three days later the ulcers were clean and appeared to be healing. The baby was seen at 3 30. At about 6 p m of the same day the baby was reported to be in considerable pain and feverish. He was hospitalized at which time the birthmarks appeared somewhat paler. The next morning all the areas were blanched and white. The surrounding skin was normal. The blanched areas also included the large lesion on the right hand. Not one of the previous nevus areas showed any evidence of circulation. Twenty-four hours later vesicles had formed on practically all lesions. The baby's temperature was 104 F and he cried continuously. The picture was typically that of moist gangrene. Dry heat was applied and gentian violet dye was painted over the skin. Blood culture and direct smears from the vesicle showed a large number of streptococci.

On the fourth day of the disease the temperature was still high and an abscess of the left wrist joint developed which, on incision, discharged a thick greenish yellow pus. He was given antistreptococcic vaccine. Within the next few days other abscesses occurred within the right wrist joint, on the dorsum of the left foot and on the right buttock (showing necrotic tissue). The angiomatous tissue continued to a state of dry gangrene and all evidence of local infection of the areas of the skin disappeared. The day after the antistreptococcic vaccine was given erysipelas vaccine was also administered and the baby was given two blood transfusions, the mother being the donor. The baby died on the twelfth day. Necropsy showed very little in the way of abscesses in the internal organs. The apparent extreme pain and the suddenness of the attack indicate that the pain was due to the complete ischemia of the large areas of the skin involved. All areas of the lesion developing an anemic necrosis simultaneously demonstrate that the origin of the vascular changes was undoubtedly hemogenous. The source of the infection was probably from the ulcers near the anus in an area impossible of complete sterilization. The progress of the disease aside from the changes mentioned was plainly that of a streptococcic bacteremia.

Congenital Lung Cysts—Adamson states that the clinical recognition of congenital cystic lung has become possible only since roentgenography and bronchoscopy have come into common use. Antemortem diagnosis has been made only within the last ten years. The condition has ceased to be a mere pathologic curiosity and has become a clinical entity of importance. It must be kept constantly in mind when making a differential diagnosis in chronic pulmonary disease of any sort. Interest is enhanced by the fact that almost any chronic condition of the lung may be simulated. Cases have been mistaken for and reported as chronic pneumothorax, chronic cavitating tuberculosis, chronic pleurisy with effusion, diaphragmatic hernia, chronic empyema, chronic abscess neoplasm and the like. Four new cases are reported and the classification, clinical characteristics and pathogenesis are discussed briefly.

Presacral Sympathectomy as Treatment of Dysmenorrhea—Shaul reviews the anatomy and technic involved in the operation and reports the results of presacral sympathectomy in three cases of obstinate dysmenorrhea and also its effect on pregnancy and labor in one case. Although an unsatisfactory result was obtained in one case, the excellent results in the other two make the author feel that resection of the hypogastric plexus in selected cases is a beneficial operation which will in time find a definite place in the gynecologist's armamentarium. It has no harmful effect on pregnancy and labor. It has no permanent deleterious effects on the bladder or rectum but

rather favorable results in relieving constipation. It should be done only in properly selected cases and after all other treatments are exhausted. It is also used as a relief measure for excruciating pain in malignant conditions of the pelvis.

Metabolism of Glycolic Acid in Progressive Muscular Dystrophy—Milhorat and Toscani studied the effect of glycolic acid on the excretion of creatine in patients with progressive muscular dystrophy. The subjects' ability to retain exogenous creatine was considerably impaired. They were kept in a special metabolism ward which permitted the quantitative collection of all specimens. The diet which was creatine-creatinine free, was supervised rigorously and kept constant for each experimental period. The nitrogen intake for the aminoacetic and glycolic periods was kept unchanged. Following an adequate control period the patients were given glycolic acid, neutralized with sodium hydroxide. There was an increase in the output of creatine when glycolic acid was given although the effect was considerably less than that produced by equivalent amounts of aminoacetic acid. When 20 Gm of glycolic acid was given the average increase in the urinary creatine was 0.057 Gm in the following twenty-four hour period. Equivalent amounts of aminoacetic acid increased the creatine output 0.188 Gm. The average rise in the creatine output after 10 Gm. of glycolic acid was 0.052 Gm., whereas the same amount of aminoacetic acid was followed by an average increase of 0.116 Gm in urinary creatine. The output of oxalic acid in the urine was determined in two subjects. During three control periods of from two to four days each, the average daily excretion of oxalic acid was from 0.001 to 0.0015 Gm. No increase in the output of oxalic acid was observed when

20 Gm of glycolic acid was given daily for three periods of four days each. The results suggest the possibility that glycolic acid can be converted into aminoacetic acid in the organism. On the other hand, the synthesis of creatine from glycolic acid without the intermediate formation of aminoacetic acid or a mere stimulatory effect of the glycolic acid on the creatine mechanism must be considered as possible, but perhaps less likely, explanations for the small increases in the creatinuria. Either no oxalic acid was formed by the oxidation of the glycolic acid or the amounts produced were less than those that the body is capable of destroying.

Roentgen Therapy of Bone Tumors—Meyerding believes that the usefulness of preoperative application of irradiation is very limited and that its indiscriminate use may be more harmful than beneficial. What is needed is early diagnosis, destruction or removal of the tumor, and prevention of metastasis by whatever means may be available. Postoperative irradiation has been employed following biopsy, excision, curettage and amputation in the hope that remaining cells may be destroyed that metastasis may be prevented or that unrecognizable metastasis may be adequately dealt with. For this reason the common sites of metastasis and the territory occupied by the lymphatic structures that drain the region of the tumor are irradiated, if the malignant cell present is of a radiosensitive type there is some hope that the remaining elements will be destroyed. The beneficial effects from this form of treatment partly result from the action of the rays on the blood vessels and the formation of connective tissue, the malignant cells that remain become enclosed in masses of fibrous tissue, of which the blood supply is impaired and growth is thus inhibited. Late recurrence may be explained in this manner in some cases, but the author has seen malignant cells at the site of previous operation and extensive irradiation when clinical manifestations of tumor were not present. Postoperative irradiation may be one of the reasons why more five year cures are recorded now than formerly but the author thinks an equally important reason is that diagnosis is made earlier than formerly and therefore efficient treatment is carried out. The response to irradiation usually will be determined by what cell is predominant. There is a difference between the radiosensitivity of tissues and cells of normal structures and the radiosensitivity of tumors. Knowledge is accumulating as to the methods of application of radiation to tumors of various situations and various cellular

classifications, at present, repeated courses of protracted fractional irradiation, with cross-firing, appears to be the most satisfactory method

Acute Transverse Bone Atrophy—Stern calls attention to the occurrence of a form of acute bone atrophy seen in fifteen young adults, usually after fixation of a limb for fracture. This phenomenon has also been seen by him in four cases after disuse because of nonpurulent infection in neighboring joints, and in two cases of tumor formation in the limb. This type of atrophy takes the form of a broad translucent band of bone resorption on the diaphyseal side of the epiphyseal line, parallel to the axis of the neighboring joint. Unlike the cases of Sudeck's atrophy, which usually occur in the smaller bones, the author's cases, with but one exception, have been confined to the long bones of the lower extremity—usually to the lower end of the tibia. There have also been three cases of transverse atrophy at the upper end of the tibia and the lower end of the femur, one through the neck of the femur (horizontal) and another vertically through the neck of the scapula. This band occupies the same position as does a similar band of radiolucency in scurvy. This peculiar form of atrophy should not be mistaken for fracture or acute disease.

Study of Alternating Scoliosis—Pitkin and Pheasant found twenty-two cases of alternating scoliosis mentioned in the literature. The apparent rarity of this condition is due to the fact that only the more spectacular cases have been reported. They found sixty-eight cases of alternating scoliosis in their records of 506 examinations for low back disability. Six cases showed the spectacular type of active alternation. The pain of alternating scoliosis is the typical sacroarthrogenic telalgia that is caused by pathologic tension in the extra-articular ligaments of the upper sacral joints. The scoliosis is caused by one or more fixed pathologic positions of one or more of the upper sacral joints. Alternation is due to a change in the fixed pathologic position of one or more of the upper sacral joints. Either sacro iliac joint may become fixed in one of four pathologic positions (sacro-iliac slips), which the authors have classified as flexion, extension, increased angle and decreased angle slips.

Studies of Cevitamic Acid and Rheumatic Fever. I. Quantitative Index of Cevitamic Acid Utilization in Human Beings and Its Application to the Study of Rheumatic Fever—Applied to subjects with rheumatic fever, the excretion tests, relative to the controls, indicated to some degree an apparent cevitamic (ascorbic) acid deficiency in eight of thirteen cases. Of these, Sendroy and Schultz ascribes the result in only two cases solely to poor diet. In the other six cases vomiting occurred or else there was an incomplete

absorption from or destruction of cevitamic acid in the alimentary canal during the test. Apparently, even in control cases, when there was a nutritional disturbance or anorexia during the test the cevitamic acid, regardless of the previous diet, was not well assimilated and was destroyed to a greater extent than usual. Through digestive disturbances patients with rheumatic fever evidently may develop a real hypovitaminosis on an ordinarily adequate diet. One would expect in such patients that the tissues might be depleted not only of cevitamic acid but of other vitamins and essential food constituents of which there may not be large reserves in the body. However, if it is assumed, contrary to the evidence of the experiments, that it is simply cevitamic acid deficiency that is associated with every case of rheumatic fever, it seems much more reasonable to regard the train of events, including digestive disturbances leading to such depletion of the tissues, as caused by an infectious process rather than to think of the cevitamic acid deficiency as initiating the infection. It seems certain that the factor of infection is present in all cases of rheumatic fever, whereas the signs of cevitamic acid subnutrition, if present, are probably incidental. Such signs of deficiency as have been found are only relative and not absolute. The average results set too high a standard of normality so that degrees of cevitamic acid deficiency, relative to the control cases previously on diets of about 100 mg of cevitamic acid a day would be exaggerated in the direction of ratings too low for cevitamic acid nutrition. When all these factors are taken into consideration it is difficult to accept subclinical scurvy as an etiologic agent in rheumatic fever.

Studies of Cevitamic Acid and Rheumatic Fever. II. Test of Prophylactic and Therapeutic Action of Cevitamic Acid—Schultz observed two comparable groups of rheumatic children, one of them receiving daily doses of cevitamic acid at intervals during the later winter and early spring. As indicated by tests of capillary permeability the development of subclinical scurvy was prevented in the treated group but the incidence of active rheumatic fever was not favorably affected by this medication. The clinical manifestations of acute rheumatic fever were not demonstrably affected by the oral or intravenous administration of cevitamic acid over periods of several months. Large doses of orange juice also were ineffective. These data are additional evidence that cevitamic acid deficiency is not a necessary factor in the etiology of rheumatic fever.

Nitrogen Metabolism in Anemia During Regeneration of Blood—Heath and Taylor studied the effect of hemoglobin regeneration on nitrogen retention, on the plasma protein and nonprotein nitrogen and on the tissue nitrogen in nine severely anemic patients. Regeneration of blood occurred during the period of observation in five patients with hypochromic anemia when iron was administered, in two patients with pernicious anemia following administration of material specifically active in this condition, and in one patient with scurvy following the administration of an adequate diet. The other patient suffering from hypochromic anemia did not receive medication during the period of observation and was used as a control. The patients were given diets that were adequate in calories but were usually low in protein. Water and table salt were unrestricted. Urine was collected for three-day periods. In two instances stools were collected for three-day periods. Venous blood was collected usually every other day. Red blood cell counts and cell volume measurements were made on this blood. The hemoglobin was measured by a specially calibrated Sahli instrument. Reticulocytes were counted daily on smears stained supravitaly with brilliant cresyl blue. The blood volume was measured, usually every fourteen days, by means of the vital red technic as described by Rowntree, Brown and Roth. All chemical analyses were made in duplicate. The plasma proteins were determined on oxalated blood plasma by the Kjeldahl method with the macro modification of Howe. The nonprotein nitrogen and the urinary nitrogen were determined by the microchemical methods of Folin. Stools were collected in sulfuric acid, mixed to a homogeneous suspension, weighed, and aliquot samples taken for determination of nitrogen by the usual Kjeldahl method. Analysis of circulating whole blood nitrogen was calculated from the hemoglobin readings and plasma protein values. Determinations of the nitrogen

content of washed red blood cells and of hemolyzed red blood cells, free of plasma and stroma, were compared with the amount of hemoglobin ascertained from the Van Slyke oxygen capacity method. It was found that hemoglobin formation is accompanied by a positive nitrogen balance only when the diet contains somewhat more than 6.2 Gm of nitrogen a day. Hemoglobin formation, however, proceeds at a normal rate even in the face of a negative nitrogen balance. The demand for nitrogen under these circumstances seems to be supplied by tissue and plasma nitrogen. With diets low in protein, extremely low values for daily nitrogen excretion may be observed during blood regeneration, and a reduction of the plasma nonprotein nitrogen is characteristic. The blood plasma seems to take an important part in the storage and transportation of nitrogenous substances. In the treatment of anemia a diet adequate in protein is necessary in order to replace tissue nitrogen that may have become diminished before or during hemoglobin regeneration.

Dietary Factors in Nutritional Muscular Dystrophy—Morgulis and Spencer could not prevent muscle dystrophy in the rabbit by the addition to the diet originally used by Goettsch and Pappenheimer 1931 (diet 13) of dry alfalfa a vegetable oil lettuce vitamin A (carotene in oil) vitamin E (cold pressed wheat germ oil) or vitamin B (yeast). Neither the omission of the ethereal-ferrie chloride treatment nor the substitution of aqueous-ferrie chloride treatment of the basic diet entirely abolished its dystrophy producing effects. Prevention of muscle dystrophy as well as cure of the dystrophy

already developed was effected by feeding the following supplements along with the dystrophic diet 13 fresh green alfalfa lettuce and vitamin E (wheat germ oil), dry alfalfa and vitamin E (wheat germ oil) or whole wheat germ. The experimental results lead to the conclusion that there must be at least two factors involved in the prevention or in the cure of muscle dystrophy. Both factors are present in fresh green alfalfa or in whole wheat germ. On the other hand, one of these factors is supplied by wheat germ oil (cold pressed), while the other is present in lettuce or in dry alfalfa. At least one of the factors is easily destroyed by ethereal ferrie chloride, by drying or by extraction with water or alcohol.

Leukemic Reticulo-Endotheliosis—Kato presents his clinical, pathologic and hematologic studies of a case of reticulo-endotheliosis (monocytic leukemia) in a male infant 18 months of age. The disease constitutes a clinical and pathologic entity that may occur at any age period. Clinically the condition is indistinguishable from any other type of acute leukemia the common symptoms being an acute course, anemia and pallor, hemorrhagic tendency and hyperplasia of the hematopoietic organs. The exact nature of the stimulus activating this multiple hyperplasia is extremely difficult to ascertain. The pathologic picture of the organs suggests a similarity to multiple neoplastic or malignant hyperplasia of the histiocytic apparatus. Because the proliferative alterations were so generalized and so extensive, the malady was inevitably fatal. No therapeutic measures are successfully applicable to such a widely and rapidly spreading process. In spite of the extreme hyperplasia of the reticulo-endothelial system the peripheral blood reflects no increase in white blood cells the one feature which stands out in sharp contrast to the conspicuous leukocytosis produced in the other reported instances of monocytic leukemia. The pathologic cells involved are large mononuclear ones, averaging from 25 to 50 microns in dimension. The qualitative blood picture is in complete conformity with that encountered in typical monocytic leukemia with quantitative increase in the total cell count. It therefore reasonably follows that "monocytic leukemia" is a synonym for leukemic reticulo-endotheliosis, the former term being a clinical nomenclature and the latter a pathologic concept. The organs which in this instance showed the greatest degree of histiocytic proliferation were the bone marrow, lymph nodes the entire gastro-intestinal tract and the thymus. The normal histologic architecture was effaced because of pronounced infiltration of these tissues by the pathologic cells. The submucosa of the whole gastro-intestinal tract was the seat of marked monocytic proliferation. Next in order of hyperplasia were the lungs liver kidneys, pancreas subcutaneous tissues the adipose tissues surrounding the heart, the epididymis and the serous membranes. In the skin the infiltration of the histiocytic elements often presented a nodular appearance.

Treatment of Adiposogenital Dystrophy in Boys—Dorff treated nine boys from 3.3 to 14.3 years of age with undescended or hypoplastic testes and with hypoplastic external

genitals (adiposogenital dystrophic type) with a therapy that varied from the gonadotropic hormone of pregnancy urine and dietary restrictions in the adiposogenital dystrophic type—hypogonad patients—to the gonadotropic principle of pregnancy urine, dietary restrictions and the supplementary use of desiccated thyroid in the adiposogenital dystrophic type—hypothyroid patients. The congenital hernia—whether potential or markedly noticeable—that accompanied an undescended testis situated intra-abdominally or at the internal ring could be corrected when the testis becomes resident in the scrotum through the stimulation of the gonadotropic hormone. While the author was not aware as to what initiated the normal descent of the testis, in cases in which there had been delay in descent this descent could be initiated by endocrine stimulation and the whole inguinal region could usually be brought to maturation in the male child through the influence of this same endocrine stimulus. The value of combined therapy was shown in that not only was genital development stimulated and genital maldevelopment corrected but also many of the other accompanying deficiencies of a skeletal, somatic or mental nature usually could be improved and redirected toward the normal.

Excretory Urography as Test of Renal Function.—Braasch and Emmett found close agreement in thirty-nine of fifty cases of various diseases of the urinary tract in which both excretory urography and differential tests with indigo carmine were used. Further study of a large series of excretory urograms was then made, grouped according to individual pathologic lesions of the urinary tract. The degree of visualization was compared with the results of other tests of renal function that had been done and with the pathologic changes observed at operation or necropsy. In hydronephrosis, pyelonephritis, polycystic disease and solitary cyst of the kidney the urograms seemed to indicate quite accurately the renal function present. In regard to renal tuberculosis and calculous disease the intensity of visualization in the urogram is often inaccurate in its estimation of renal function. Indigo carmine seems to be slightly better but is also inaccurate. However the additional data furnished by the urogram as to the anatomic deformity present make up for any disparity in this regard and render excretory urography almost indispensable in the diagnosis of these conditions. In the field of malignant renal tumors excretory urography will often suggest the amount of function remaining, but it is not to be relied on as an index to the extent of neoplastic involvement. With urinary obstruction such as is found in hypertrophy of the prostate gland excretory urography gives valuable information as to renal function. In this condition the picture of the anatomic deformity is exceedingly valuable, as dilatation of the upper part of the urinary tract is common and can be produced even in the presence of a normal value for blood urea.

Carcinoma of Female Urethra.—Watson states that as a urologic lesion carcinoma of the female urethra is being encountered and recognized much more frequently than formerly. It

may appear in the third decade of life but usually in the fifth decade. A positive Wassermann reaction may be present and so mask one's best efforts in arriving at an early diagnosis. A single biopsy specimen obtained from a urethral growth may be misleading in the information obtained. In the case of the report "no malignant condition found" the so regarded benign lesion should be carefully watched and, when healing is unduly delayed, further sections obtained. One fourth of the patients in the author's series of seventeen had had "growths" removed from the urethra previously, a predisposing factor to malignant growth. Early recognition and properly instituted treatment gives an appreciable measure of palliation. A four year cure and probably longer may be expected in more than 50 per cent of the cases.

Furunculosis of Auditory Canal.—Freund has found bacteriophage a valuable agent in aborting as well as curing furunculosis of the external auditory canal in the early stages. A number of his patients have shown such prompt response to this method that he recommends the procedure before attempting any other form of treatment. Of more than fifty cases, less than 2 per cent required surgical intervention. The others responded satisfactorily to from three to six applications, supplemented in most instances by one or two injections of the bacteriophage. Bacteriophage injections may be given either in a remote part of the body or directly into the infected area. The bacteriophage is obtained in 20 cc. vials and can be used either for topical application or for hypodermic injection. Streptococcus bacteriophage yielded poor results in the few cases tried. In contrast, the staphylococcus bacteriophage was strikingly effective in practically every case. The staphylococcus bacteriophage was helpful even in the instances in which the streptococcus failed. Furunculosis of the external auditory canal is to be differentiated from mastoiditis, aural polyps, perichondritis, exostoses, carious teeth and granulations.

The Common Cold and Asthma.—In a study of 455 consecutive allergic patients, Bernton encountered seventy-one who claimed that a cold was responsible for their asthmatic seizures. The age of twenty-seven patients was 10 years or less. Fifty-

one patients gave a positive family history for some manifestation of allergy. The patients readily submitted themselves to tests for protein sensitization. The possible alleviation from the recurring distress proved the incentive to an allergic study. The tests were performed by the cutaneous method with epidermal and miscellaneous proteins, including house dusts, pollens, molds and protein extracts of food materials. The results of the tests show that in the group with a positive family history thirty-six patients have shown positive cutaneous reactions, whereas fifteen have shown negative reactions. The high percentage of positive reactors is in accord with the concept that the tendency to hypersensitiveness is inherited. The clinical evidence definitely points to the common cold as the important predisposing factor to asthma in this group of patients. Forty-four patients in the series gave positive reactions to the various allergens employed. A reaction was adjudged positive if it consisted of a wheal with pseudopodia and a zone of redness, and if it produced a sensation of itching. The inhalant group of allergens yielded more positive reactions than the ingestants, and of the inhalants the pollens ranked first. There is general agreement on the fact that infection during the course of a cold is capable of provoking the asthmatic state. The causal relationship of the common cold to asthma may be summarized as follows. According to one school, the micro-organisms isolated from the sputum are the exciting factors. The other possible view is that a filtrable virus is the contributory factor. In either, even the asthmatic paroxysm is the response of an active and sensitive vagus system to a foreign protein. The basis for the sensitive vagus mechanism in the allergic may be dependent on subtle physicochemical changes.

Results of Tonsillectomy in Allergic Patients—Of 1,112 patients with hay fever and asthma, Waldbott and his associates performed tonsillectomy in 228 before the onset of allergic symptoms and in 205 after allergic manifestations had developed. In the 205 allergic individuals, tonsillectomy resulted in definite relief in 19 per cent, temporary relief in 19 per cent and aggravation of the allergic symptoms in 11.6 per cent. In a control group of sixty patients in whom tonsillectomy was performed after they had been under the authors' care, the results were substantially the same. Tonsillectomy, when performed for conditions other than allergy, was successful in 35.2 per cent of the allergic group and in 36.4 per cent of the "preallergic" group as compared with 72 per cent improvement recorded in normal controls (Kaiser). In 228 patients in whom tonsillectomy was performed before the onset of allergic symptoms, 14.4 per cent developed allergic manifestations within three months, 29.3 per cent within six months and 48.6 per cent within two years after operation. This compares with 26 per cent showing frankly allergic symptoms within three months, 47 per cent within six months and 63 per cent within two years in patients whose tonsils were removed for the relief of "nasal colds" and "bronchitis." Most benefit from tonsillectomy was obtained in the earlier age groups. The operation was practically always a failure in patients more than 25 years of age. The efficacy of the technic of removal did not affect the result. The operation was less successful when performed during the pollen season. Although the results of tonsillectomy were disappointing the authors believe that tonsillectomy should be performed in patients having frequent infections. In others with allergic catarrh of the upper part of the respiratory tract

which may or may not involve the tonsils, they believe that tonsillar tissue is a definite asset to the system and should be preserved.

Plastic Repair of Facial Defects Resulting from Radical Extirpation of Cancer—Owens states that facial defects following the radical extirpation of cancer are modified by the resulting loss of tissue and that the method of repair indicated is therefore determined by the extent and location of the deformity. As a result of observation of complications due to certain types of treatment, it is suggested that growths involving skin over cartilage should not be subjected to irradiation because of the high percentage of cartilaginous destruction that follows this procedure. Treatment of cancer by x-rays or radium should always be done by a specialist, competent through long experience to apply radiation in amounts that are adequate.

Patients are too frequently seen who have received inadequate irradiation, and as a result of late manifestations they subsequently seek treatment for lesions that are hopelessly advanced. Microscopic study of all tissue removed by means of the frozen section method should be routine. By means of this technic more involved tissue will frequently be removed which otherwise would have been permitted to remain because of its normal macroscopic appearance. Much can be accomplished in the restoration of defects resulting from the eradication of cancer. Many patients would be less skeptical in subjecting themselves to the eradication of a growth if they could be assured that unsightly deformities would not be a necessary sequel.

Cytology of Nasal Secretions—In connection with their cytologic and clinical studies of rhinosinusitis, Hume concludes that 1 The polymorphonuclear leukocytes present in the nasal secretions indicate an acute inflammatory reaction. 2 The lymphocytes present in the nasal secretions indicate chronic inflammation with round cell infiltration of the subepithelial layers. 3 The eosinophils present in the nasal secretions in numbers greater than 5 per cent suggest a hypersensitivity, and proper tests should be made before surgical procedures are instituted other than ventilation and drainage. The eosinophil is present only when an allergic background is existent. Its origin and function must be better understood before its exact relation to allergy is established in fact. 4 The presence of the large monocytes in the nasal secretions should be considered as a favorable omen, it indicates that a maximal reparative effort is being made cytologically to combat the pathologic processes. 5 Polymorphonuclear leukocytes or lymphocytes present, in conjunction with eosinophils, would at least suggest a bacterial invasion on an allergic background. 6 The study of the nasal smear should be instituted as a routine measure. With a reasonable degree of accuracy and by a simple procedure one can determine whether one is dealing with an acute inflammation, a chronic process or a possible allergy or an allergy complicated by infection. 7 Smears examined during the treatment of a case will afford information as to the progress being made. 8 It does not seem improbable after many thousand nasal smears have been examined and correlated with the physical and pathologic observations that it will assume the importance as a diagnostic measure that the differential white cell count holds in general infections.

Trichomonas Vaginal Infestation.—Salberg and Brunet point out that the true role of the trichomonas as the cause of persistent and at times intractable leukorrhea has not been established. The two strains of the parasite recognized are

Trichomonas hominis, which is found rarely in smears and cultures from the mouth and intestinal tract, and *Trichomonas vaginalis*, which is discovered in the vaginal secretion. All the cultures have a characteristic odor and form gas. The strains that have been isolated from the mouth and lower intestinal tract of apparently normal individuals are usually smaller and somewhat less active and are more difficult to culture than those isolated from the vagina. The strain of the parasite from the vaginal secretions produces a peculiarly offensive sourish odor. There undoubtedly is a tissue susceptibility of the vagina—sensitization of an unknown source—in women who are infected. The pathogenicity of the organism is still in doubt and many gynecologists and parasitologists think that other organisms found in the vaginal secretion prepare the soil for the entrance of the trichomonads. Some physicians believe that the primary factor in these infections is a fungus, *Monilia*, and that the trichomonas occurs symbiotically as a nonpathogen. In many studies of the flora of the vaginal tract it has been demonstrated that the organisms commonly found in healthy individuals and in nonspecific symptomless leukorrhea are frequently associated with the trichomonads. The fact that trichomonads are rarely found in acute gonococcal infections and yet are observed in chronic specific cervicitis leads one to surmise that there is an unknown characteristic of cell protoplasm and tissue fluid which under certain conditions exerts a specific influence and causes the trichomonas to become pathogenic. The most frequent complaint that brings the patient to the physician is a vaginal discharge. In a majority of cases there is an increase of the symptoms prior to and following the menses. Many patients will give a history of an acute vaginal discharge, which subsided without medical attention only to recur at the subsequent menstrual epoch. A leukorrhea, usually copious, watery and foaming or frothing, beginning somewhat suddenly with external smarting and a very disagreeable, sourish odor, is the usual subjective observation. The three principles of great importance to be observed in the treatment of this infection are the maintenance of efficient drainage, the use of a weak antiseptic to destroy the parasites which can be reached, and mild stimulation of the tissues to increase their resistance to the trichomonads. Gentle cleansing with cotton sponges of the entire vaginal tract with tincture of green soap and water is important as a preliminary measure in any type of treatment. In the authors' experience 80 per cent of the cases will be controlled by simple methods, but the remaining 20 per cent will be subject to recurrent exacerbations and in these cases powders are the most efficacious. Following a gentle cleansing and thorough drying of the vaginal canal, the vagina is filled with a compound of fullers' earth, kaolin and talc.

Measurements of Distribution of Gamma Radiation.—Wilson and Myers aimed (1) to measure directly in human tissue the intensity at various depths due to the radiations from a 2 Gm unit and to compare and contrast the results with those obtained by measurements in a water phantom, (2) to determine whether bone possesses any features which modify the measurements in a manner not obtaining in soft parts, and (3) to collect some data concerning "back-scatter" at the surface of the skin. The results of their study indicate that measurements of the gamma radiation from a telerradium unit made at a point within a water phantom give an accurate measure of the dose received at a corresponding point within the human body, provided it is situated within an extensive amount of tissue that contains no air spaces. The types of tissue that are concerned make no difference to the result. When, however, regions near the boundaries of tissues have to be considered, it appears that readings made within the more extensive water phantom may differ considerably from the true values. Thus, for a true measurement in such regions it is necessary, as Bruzau has pointed out, to use a volume of water (or other phantom material) equivalent to that part of the body undergoing irradiation. The removal of the bone of the skull apparently brings about an increase in the depth dose within the skull of about 12 to 13 per cent, an amount that is not in itself sufficient to justify the removal of the bone as a preliminary to irradiation, though of some value if applied to cases in which a preliminary decompression is performed for therapeutic reasons or as a step in the exploration of the tumor.

Bacillus Coli Infection and Rheumatoid Arthritis.—Slot and Deville observed that in nine of their twenty-four cases of rheumatoid arthritis there was an unsuspected bacilluria. *Bacillus coli* was the organism isolated in eight cases,

and a streptococcus was present in one. None of these patients, except the one harboring streptococci, complained of any urinary symptoms and the usual routine ward examination of the urine revealed no abnormality. It was only when catheter specimens were taken that the bacilluria was discovered. As the administration of alkalis is generally an early form of therapy, it is possible that the presence of bacilluria is more frequent than is thought. The role of the intestine in rheumatoid arthritis must be reviewed carefully, in view of the possibility that *Bacillus coli* infection may have an intestinal origin. A careful bacteriologic examination of the feces was made in all the authors' cases, but no abnormal flora was discovered. All the patients were females, and the arthritis in all cases was confirmed not only clinically but also by roentgen examination.

Tuberculosis of Tonsils and Uterus.—In 2,477 cases in which tonsillectomy was performed, Krishnaswamy and his associates found histologic evidence of tuberculosis in fifteen cases. The disease is definitely much more frequent in females than in males after 15 years of age. The maximal incidence is between the ages of 16 and 20. The youngest patient was 5 years and the oldest 26 years of age. The tuberculous process begins in the form of one or two discrete tubercles beneath the surface epithelium and crypts. These gradually enlarge, become confluent and extend into the substance of the tonsil until a great part of it is replaced by tuberculous tissue. Ulceration does not occur. Proliferation of the reticular cells and fibroblasts was pronounced. The ultimate tendency of the tuberculous lesions in the tonsils is toward recovery. Tuberculous infection may spread to the peritonsillar tissues, causing peritonsillitis, which was clearly seen in one case. Tuberculosis of the uterus is most common in adults, the average age incidence in the authors' eight cases was 28. The most common symptom was leukorrhea, even though some of the patients complained of amenorrhea and others of vaginal bleeding. The duration of the symptoms varied from a period of five months to six years. There was histologic evidence of tuberculous cervicitis in all cases except one. The pre-operative diagnosis in most cases was that of malignant disease, showing that histologic examination of the affected tissue is of particular importance in the correct diagnosis of uterine tuberculosis, since there are no definite clinical signs or symptoms pathognomonic of this disease. In three cases there was no evidence of any other focus of tuberculosis apart from the cervix and the possibility of primary tuberculosis of this tissue is to be considered. The endometrium was not affected at all and the myometrium showed miliary tubercles in close relation to the blood vessels, suggesting a hematogenic spread. Histologically, in early cases the tubercle follicles are situated beneath the surface epithelium in the stroma between the glandular acini. These gradually coalesce, undergo caseation and cause ulceration of the surface epithelium. A rare interstitial type has been described in which there is a diffuse enlargement of the cervix with intact surface epithelium (Frank). There was one case of this type. It has been noted by some authors particularly by von Franque, that in tuberculosis of the cervical mucosa there is stratification of glandular epithelium and obliteration of the lumen of the acini. This has not been observed in the present cases.

Experimental Investigation of Tinnitus—McNally and his associates carried out experiments in a series of nineteen patients suffering from tinnitus, the ages of the patients varied from 19 to 52 years, the duration of the tinnitus varied from a few months to about thirty years. Some of the youngest patients or ones who have had the tinnitus for a very short time did not show as much improvement from the various procedures as did older patients or the ones who have had the tinnitus longer. Both ephedrine and a preparation containing the alkaloids of belladonna caused improvement in the tinnitus in a greater percentage of cases when given by mouth than when given hypodermically. Since the hypodermic method of administration was the more accurately controlled, its results are probably more reliable. Stimulation of the sympathetic or depression of the parasympathetic nervous system by drugs whether carried out separately or simultaneously, had a slightly more beneficial effect on the tinnitus than did depression of the sympathetic or stimulation of the parasympathetic nervous system. Yet the operation of stellate ganglionectomy (depression or elimination of the sympathetic) caused an improvement in the tinnitus in three of four cases. The procedures carried out, with the exception of the sodium-free diet, were directed toward alteration of the cerebral circulation or cerebral pressure. It is most likely that the cerebral circulation was affected because the drugs used produced their full physiologic effect and most of these drugs have been shown by other experimenters to have a definite effect on the cerebral vascular mechanism. In spite of an undoubted alteration of cerebral circulation, the tinnitus in the majority of the cases was unaffected by the procedures employed.

Effect of Storage on Drinking Water of Ships—Jones investigated the changes in the *Bacillus coli* content of fresh water which occur during storage in ships tanks under normal conditions at sea. Four experiments were performed over a period of fifteen months, the same tank being used for each and from these the following conclusions are drawn. 1 *Bacillus coli* dies out during storage, and no evidence of any increase,

either temporary or permanent, was found. 2 If *Bacillus coli* is found in samples of water taken from ships' tanks, it can be assumed (provided the tank itself is not contaminated) that these germs have not grown there and that the water contained a higher number of *Bacillus coli* when it was taken into the tank. 3 The rate at which water becomes free from *Bacillus coli* depends on the temperature to which the tank is subjected, being rapid in the tropics and much slower on voyages through cooler seas. 4 Whether or not the storage tank has been recently cleaned and "cement-washed" inside does not appear to affect the rate of purification of the water, at any rate up to a period of fifteen months.

Actinomycosis of Ovary—Coté and Tudhope have observed four cases of actinomycosis of the ovary within the last twelve years. The ages of the patients ranged from 27 to 45 years. The total duration of the illness in cases 2, 4 and 1 was five, nine and twelve months, respectively. In case 3 it was four years and three months, but this includes a preliminary period of three years of rather vague attacks of abdominal pain at infrequent intervals. In cases 2 and 4 there had been an operation for "appendicitis" three months prior to their coming under observation for pelvic trouble, and in case 1 the appendix was embedded in a mass of dense adhesions anchoring the cecum to the floor of the pouch of Douglas. It is also highly significant that in all four cases it was the right ovary, with or without the corresponding fallopian tube, which was first affected. In cases 2 and 4 only the right ovary was removed. In case 3 the right tube and supposed ovary were first excised but were not examined microscopically, nine months later a "cyst" of the right broad ligament was removed and proved to be an actinomycotic ovary. In case 1 a right "tubo-ovarian abscess" was excised at the first operation but was not examined microscopically. Three months later the left tube and ovary were removed and the actinomycotic nature of the lesion was demonstrated microscopically. It is reasonable to assume that in these cases the right tube and ovary were affected by direct extension from the appendix. All four patients died of the disease in spite of the surgical measure adopted, and in cases 2 and 3 there was extension finally to the lungs and pleurae. Actinomycosis of the ovary reproduces with great fidelity the characteristic honeycombed appearance of the lesion as ordinarily encountered in the liver and kidney. Typical colonies of the ray fungus were present in the suppurating centers of the granulomatous nodules, and in one case an anaerobic streptothrix was recovered in cultures from the empyema that developed subsequently.

Chlorophyll and Hemoglobin Regeneration After Hemorrhage—Hughes and Latner found that rabbits are capable of converting chlorophyll to hemoglobin, if the former is given in small doses. The failure of large doses to produce any effect is very remarkable. It seems that chlorophyll in large doses is toxic to the bone marrow. This may be due to increased absorption of magnesium either in combination with chlorophyll or brought about in a manner similar to that in which the absorption of iron is increased on administration of bile pigments. The fact that large doses of the magnesium-

free chlorophyll derivative aid regeneration when administered by mouth seems to bear out this suggestion. It is a distinct possibility that the chlorophyll is acting as a physiologic stimulant of the bone marrow and is not really concerned with the actual chemistry of regeneration of the porphyrin grouping. This possibility is now being investigated. In the case of the crude chlorophyll, large doses exert a favorable effect on hemoglobin regeneration. It seems, therefore, that there is some substance in the crude chlorophyll which counteracts the toxic effect of the chlorophyll itself. The part played by intestinal bacteria might possibly be of some significance. Chlorophyll is known to be broken down by these bacteria, and it is quite likely that it is one of the breakdown products which is used for the subsequent synthesis of hemoglobin. This possibility is borne out by the failure of subcutaneous injections of the chlorophyll-free derivative to produce any effect.

Early Diagnosis of Carcinoma of Cervix.—Schiller warns that the aqueous iodine test is not specific for carcinoma but marks off only the areas that do not contain glycogen. Glycogen is always absent in cancer, but not only in cancer. It is absent also in carcinomatous transformation of epithelium, hyperkeratosis of the squamous epithelium of the cervix, keratinization developing in prolapse, which may also cause the glycogen to disappear, and when the superficial layers of glycogen containing epithelium have been rubbed off by inflammation, maceration or the examining finger or speculum. Thus there are different possibilities which cause the epithelium of the surface to remain white. The method of iodine painting is easily carried out in an outpatient department, requiring no special training for the doctor and causing the patient no pain. A further field of application for iodine painting is in the revelation of cancerous marginal zones of progressed carcinomas. The method can be applied without difficulty, but it has its full value only when carried out on as many patients as possible. The author has seen patients 25 or 26 years of age with smooth, homogeneous shining white portions that seemed altogether above suspicion to the eye of the clinician but when painted with iodine showed a small white speck which proved to be a carcinoma when scraped off. The gynecologist who paints only the suggestive cases is sure to miss the most important stage—the smallest clinically latent cancer. The more general the examination by iodine painting the smaller will be the proportion of positive cases. In the author's last series, about twenty of every

hundred women examined in the outpatient department showed suspicious areas, and of these twenty only one or two proved to be cancers at histologic examination of the scrapings. But even if only 1 per cent of the examined women give a positive diagnosis, the result is still exceedingly satisfactory, for carcinoma when detected and treated at that early stage gives nearly 100 per cent security for definite permanent healing. If it were possible by this procedure to examine systematically at intervals of a few months as large a number of women as possible, a predominant proportion of cervical cancers might be obtained for treatment at such stages as would fully guarantee permanent healing. Thus it would be possible to lower greatly the mortality of this disease.

Syphilis and Yaws Among Australian Aborigines.—Hackett gives a critical survey of some references to venereal disease and syphilis in Australian aborigines and suggests that, if granuloma pudendi is excluded, in most cases the disease referred to is yaws. Among the aborigines of the Northern Territory of Australia today syphilis is unknown, while yaws is frequent. In museums in Australia there are aboriginal bones from the southern and eastern areas which show yaws lesions. It is probably correct to conclude that, when Australia was discovered by Europeans, yaws was present in all native communities and that, as long as they were leading lives not completely divorced from their bush fashion, they still suffered from yaws and not from syphilis. This confirms the suggestion that the descriptions of venereal disease and syphilis were of yaws. That the disease known to the Aranda tribe as *irkinja* is yaws indicates that that disease has been endemic in central Australia for a long time.

*What Is a Cold? H. Merrill.—p. 550
Catering at a Spa from the Practical Man's Point of View. M. Chance.—p. 554

What Is a Cold?—Merrill declares that a cold is the visible manifestation of conflict between microbes and lymphocytes of more vigorous degree. Every microbe which obtains a foothold in the throat or nose stimulates the defenses into more vigorous action and will produce the catarrh, swelling of the mucous membranes and increased irritability, with sneezing and coughing, for these are the actual consequences of the increased production of lymphocytes and mucus. The exanthems are all of them attended by catarrh, the main feature of a cold. The condition which brings about this degree of reaction is the lessened bodily resistance to microbic attacks that is occasioned by a loss of bodily heat. A cold is the manifestation of the conflict between microbes and lymphocytes, which is a normal condition of life, exaggerated in severity when the invading microbes have overcome the first line of defense through the weakening of these outposts, which supervenes on a sudden loss of heat. The actual cause of this cooling of the body is evaporation. The usual way in which a cold is caught is by sitting in wet garments, particularly wet shoes and stockings. Evaporation is greatly expedited in a draft. The air cannot be too cold to breathe as long as we are protected from loss of body heat. In the course of passage from the open air to the nasopharynx, the inhaled air is raised to blood heat. While it is both healthy and safe to sleep in a draft when in bed it is highly dangerous to sit in a draft unless one is protected by an overcoat such as would be worn when sitting or riding in an open vehicle in the open air.

Risk of Silicosis in Sandblasters—In the case of chambers using sand as the abrasive, Merewether gives the following as the main sources of risk (1) the atmosphere inside the chamber is invariably dangerous during blasting and for a period afterward, (2) the atmosphere inside the helmet, breathed by the worker, is invariably dangerous during blasting in the absence of an adequate positive fresh air supply and (3) the air in the workroom in which the sandblasting chamber is situated may also be dangerous, owing to leakages from the chamber and from various parts of the accessory plant and from opening the door before the dust has been removed by the fan While it may be possible with special equipment precautions and constant supervision to make sandblasting safe for the time, a breakdown in one direction or another is more liable to occur than in many of the dangerous trades and the results of such a breakdown, even if only of a temporary nature, are most serious Owners of sandblasting factories have many fresh problems daily, sandblasters are often piece workers and therefore are less careful, the sandblasting equipment has to stand up to very hard usage, and thus, without any real negligence, the general conditions under which sandblasters work become such as to result in a serious health hazard

Immunizing Power of Smooth Colony Tubercle Bacilli—Negre and his collaborators inoculated guinea-pigs and rabbits subcutaneously or intravenously with tubercle bacilli from smooth colonies isolated by the acetone extract method The original organisms were obtained from human pathologic lesions or from guinea-pigs and transferred for several generations The injections produced in these animals a benign infection, the histologic manifestations of which were transitory but seemed to be prolonged by the persistent presence of bacilli in the animals. Following these injections the guinea-pigs and rabbits presented a definite resistance to infection with virulent organisms This resistance was more marked after inoculation with the smooth variety than with the rough avirulent variety from the same strain of bacilli The more marked immunizing action of the smooth strain perhaps depends on its special chemical composition, since its content of lipids is higher than that of the corresponding rough varieties Whatever the origin or character of the strains used and whether they return or not to the virulent rough variety, all the smooth strains studied showed feeble variations but the same immunizing power against tuberculous infection with virulent organisms of either human or bovine type. These properties seem to remain intact after several years of cultivation of the smooth strains on artificial mediums After heating for one hour at 70 C, the bacilli of the smooth colonies, like those of the rough colonies, appear to lose the greater part of their immunizing power

Aerophagia in Ptosis—Gachlinger believes that the theory of Jacquet most nearly explains the presence of air swallowing in ptosis This theory involves the conception that most patients with ptosis are dyspeptic and that this gives rise to gastric malaise, which causes the deglutition of air The facts that the symptom subsides with the patient in the lying position that it is temporarily cured by diet and, finally, that the wearing of a support can cause the disappearance of aerophagia in reducible ptosis lend support to this theory The author carries this theory further and believes that aerophagia in ptosis is the consequence of insufficient pressure exerted by the abdominal muscles on the gastro-intestinal mass It is hence partly due to the result of poor physiologic absorption of the gas, partly to disorder of the hepatic circulation and partly to insufficiency of the interior tonus

Synovial Chondromatosis Case. P C. Borsotti—p 63

Isolated Fracture of Greater Trochanter—Betto states that isolated fractures of the greater trochanter are rare. They are the result of direct trauma and violent contraction of the muscles during trauma Osteoporosis is a secondary factor The

diagnosis is difficult. Palpation cannot be performed because of the presence of edema and intense pain. The position of the limb is characteristic. There is adduction of the thigh, internal rotation of the leg in such a manner that the patella touches the internal aspect of the opposite knee, moderate flexion of the leg on the thigh and slight deviation of the pelvis to the normal side. The differential diagnosis is made with articular lesions and with fracture of the neck of the femur. The diagnosis is made by the roentgen examination of the femur, which shows the type of fracture and intensity of displacement of the fractured segment of the process. The prognosis with regard to function of the limb depends on the type of fracture and the intensity of the displacement, which depends in turn on the direction and retractile force of the muscles. The treatment consists in rest with the leg in external rotation and forced abduction for about one month, if the fracture is incomplete and the fractured segment remains in place or is slightly displaced. Surgical treatment is indicated only in cases of grave complete fracture with great displacement in young patients. A case is reported.

*Influence of Vitamin C on Coagulation of Blood. L. Cotti —p 483

Influence of Vitamin C on Coagulation of Blood—Cotti found in previous work that intravenously administered vitamin C (from 50 to 100 mg daily for from five to eight days) produces variations of the time of coagulation which are related to variations of the coagulation ferments. To ascertain the role of the coagulation ferments, the author made determinations of the time of coagulation and of the amount of thrombin, fibrinogen and antithrombin in the blood of eleven persons, including normal persons and persons suffering from hemorrhagic and nonhemorrhagic diseases, before and after an intravenous injection of from 100 to 200 mg of vitamin C. The time of coagulation was prolonged in the four cases in which the amount of thrombin decreased, it was shortened in the four cases in which the amount of thrombin increased and it did not change in the three cases in which the amount of thrombin did not change. Fibrinogen and antithrombin did not change. The results obtained point out the relations between thrombin and coagulation and the fact that vitamin C promotes the activity of thrombin when it is diminished and inhibits it when it is normal. The last statement is proved by the variations of the coagulation time that follow the intravenous injection of vitamin C in persons with hemorrhagic diatheses, including hemophilia, and in certain normal persons. The coagulation time is shortened after the injection of vitamin C in all cases of hemorrhagic diathesis while it is prolonged in certain normal persons. On the basis of the results of the studies of Kühnau and Morgenstern on coagulation "in vitro" and of his own results of the study of coagulation in living persons, the author states that coagulation takes place through certain phenomena of oxidation-reduction of substances in the blood and that the mechanism of action of vitamin C on coagulation is due to the reducing properties of vitamin C.

Pneumoperitoneum in Treatment of Intestinal Tuberculosis—Rey and his collaborators report satisfactory results from pneumoperitoneum in fifteen cases of intestinal tuberculosis secondary to pulmonary tuberculosis. The authors conclude that the technic of pneumoperitoneum is easy. It is advisable

to perform the operation early in the development of intestinal tuberculosis, as soon as the complication is suspected. The operation is not contraindicated in patients in whom unilateral or bilateral pneumothorax has been previously performed. Pneumoperitoneum acts as a coadjuvant treatment to phrenicectomy by intensifying and strengthening the effects of phrenicectomy. Pneumoperitoneum results in rapid relief of diarrhea, pain, fever and the symptoms of gastric dyspepsia until complete disappearance. The patients regain a restful sleep and a feeling of euphoria. The satisfactory results of pneumoperitoneum as a symptomatic treatment are obvious. The value of the operation in producing complete recovery of the patients will be evaluated in time, after a more prolonged observation of the patients who, up to the present, can be considered as recently treated.

Typhoid General Study. G. González —p 380

Identification of Diphtheria Bacilli—A rapid method for identification of diphtheria bacilli and detection of carriers as described by Brahdý and his collaborators, was published in THE JOURNAL, May 25, 1935, page 1881. The method consists in the use of horse serum instead of Löffler blood serum slant method in the preparation of nose and throat cultures for identification of diphtheria bacilli, and in the intracutaneous test in guinea-pigs after inoculation of a four-hour rapid culture, transplanted to a Löffler slant and incubated for eighteen hours, for detection of carriers. Silveira made a comparison of both the routine Löffler and the Brahdý method. He confirms Brahdý's conclusions with regard to the simplicity of the technic, rapidity of results and value of the method. In Silveira's ten cases positive results in identifying diphtheria bacilli were obtained within two and four hours by Brahdý's method as against a period within sixteen and twenty-four hours, rarely twelve hours, by the routine Löffler method. When the Brahdý method gave negative results, the Löffler method also gave negative results. In detection of carriers positive results can be reported within twenty-four hours by Brahdý's method as against four or five days by the routine Löffler method. Also in this case negative results of one method coincide with negative results of the other.

*Some Peculiarities of Urine in Multiple Myeloma. A. Magnus Levy —p 188

Pathogenesis of Obesity—Hetenyi thinks that anomalies in the transport of fat, particularly in its mobilization, play a part in the pathogenesis of obesity. He investigated the mobilization of the fat depots of the organism during insufficient food intake in obese and in normal persons and found that it is impaired. Then he studied the alimentary hyperlipemia in obese and normal persons and observed that the tissues of obese persons have a great avidity for fats that enter the blood stream. The alimentary hyperlipemia was considerably less in patients with obesity than in normal persons. The author studied the relation between fever and fat mobilization from the deposits, the action of dehydration on the blood fat and finally the resorption of the subcutaneously administered fat. He detected that the increase in the blood fat during the artificially produced

fever is slight in obese persons. The resorption of subcutaneously administered fat is much less in obese than in normal persons. The author concludes that all these experiments show that the mobilization from the fat depots is reduced in obese persons, whereas their absorption capacity for the circulating fat is greatly increased, that is, obesity is a disorder of the fat mobilization. He concedes, however, that the problem of the pathogenesis of obesity has not yet been completely solved.

Peculiarities of Urine in Multiple Myeloma—Magnus-Levy points out that it is characteristic for multiple myeloma that casts and epithelia may for a long time be completely absent from the urine, in spite of severe degrees of proteinuria. The kidneys may remain intact for a long time, but later they usually became involved and casts appear in the urine. Some of these casts differ from the usual forms. There were casts with coarse granules and of irregular shape. Another type of cast resembled the well known waxlike ones but were much lighter and more transparent. The author shows that although these casts are of no importance for the diagnosis, they have a theoretical significance in that something can be learned about the nature of their protein, which is not possible in the ordinary types. Globulites, spherical bodies, which often appear in layers and the size of which exceeds that of leukocytes once or several times, were occasionally mentioned in earlier descriptions as constituents of the sediment but have been practically disregarded in recent years. Because of their low solubility they had never been chemically analyzed. It seemed likely that the spherical bodies would contain crystalline material. The author succeeded in proving their presence. In a considerable number of cases of multiple myeloma he observed a peculiar behavior of the Bence Jones protein during the process of heating. In spite of a sufficient acid reaction, a considerable portion of the Bence Jones protein remains undissolved during boiling over a flame. However, it does not precipitate like dust or in flocules, like ordinary protein, but is leathery, tough and sticky. Another portion of the sediment which forms a foam when the boiling process is severe, is likewise sticky. Of the urines with high protein content, every fourth or fifth one shows this behavior. It represents the transition of a solid sediment into a more or less fluid one, a type of "melting." After describing further studies on this type of melting, the author discusses the requirements for the demonstration of Bence Jones protein. He mentions three points: the proper solution of the urine with solution of sodium chloride, the addition of sulfosalicylic acid and the slow heating.

Cod Liver Oil and Plaster Cast for Osteomyelitis—Löhr describes the technic of the cod liver oil and plaster cast treatment in acute osteomyelitis. The field of operation is rendered bloodless and an incision is made over the painful part of the bone. The periosteum is opened and the pus evacuated. The wound is filled with cod liver oil ointment, care being taken that it enters all corners. The wound is closed loosely, so that pus can escape readily. The filling with the mild ointment takes the place of rubber drains and tampons. The external wound is covered with a thick layer of ointment, and over this a plaster-of-paris cast is applied. As a rule the cast is left in place for two or even three weeks, but in case of excessive secretion from the wound it may be removed earlier. At the removal of the plaster cast the wound is usually more or less healed. Roentgenoscopies that are made during the following period often reveal sequestrums. However, sequestrotomy should not be done too hastily, because particularly in young persons, considerable restoration of the bone takes place. If six or eight weeks after the beginning of the disease, sequestrotomy does become necessary, it should be done in a radical manner. The author discusses the use of cod liver oil and the

plaster cast in cases of chronic osteomyelitis. In these cases the radical removal of the disease focus is of primary importance. The author says that in some cases he did not even hesitate to open the foot or knee joints. This procedure had no untoward effects. In summarizing the advantages of the cod liver oil and plaster cast treatment of osteomyelitis, the author stresses the painlessness, the fact that the frequent changes of dressings is done away with and the fact that the general condition of the patients is favorable. He cites a case which indicates that even desperate cases are amenable to this treatment.

Question of Operative Treatment of Strawberry Gallbladder—Bernhard and Fenster say that during the period between 1906 and 1935 there were 443 cases of strawberry gallbladder in which operation was performed at the surgical clinic of the University of Gießen. Of these, 380 were in female and sixty-three in male patients. The age incidence was the same as that noted in cholelithiasis. Pain in the right upper quadrant and typical colics were the prominent symptoms in 380. In 100 patients jaundice was either present or existed at some time. In 100 cases, stones were present. Their composition differed from that seen in cholelithiasis. In fourteen instances out of twenty-four, sugar tolerance tests gave abnormally high sugar curves before the operation. Diastase determination in twenty-nine patients before the operation demonstrated an increase in one fourth of the cases. They have observed cases with a normal blood sugar curve but with increased diastase or pancreatic lipase in the blood serum. The quinine-refractory liver lipase was frequently increased. In about half of the cases either the external or the inner pancreatic secretion was found to be disturbed. Tests of pancreatic function are therefore of value in the diagnosis of strawberry gallbladder. Differential diagnosis from cholelithiasis and stasis of biliary tracts is difficult. Of the 443 patients, eleven died following the operation and twenty-seven after leaving the clinic. Seventeen of the latter died of carcinoma. Two hundred and one patients replied to inquiries and 110 were reexamined. In 80 per cent of the follow-up cases, relief of complaints was complete, while in 10 per cent the operation was considered a failure. Subacidity and anacidity following the operation were observed with about the same frequency as after the operation for cholelithiasis. The frequent occurrence of alimentary glycosuria and the abnormal blood sugar curve, as well as the increase of the atoxyl-refractory blood lipase, point to the existence of a chronic pancreatitis, which the authors regard as the cause of postoperative complaints. Operative intervention, though justified, is not as urgent as in cholelithiasis. It is clearly indicated, however, in the presence of pain and colicky attacks. From present knowledge the strawberry gallbladder is to be regarded as an independent disease entity and in many cases as the forerunner of cholelithiasis.

Treatment of Hemolytic Shock—Eljasevič reports three cases of hemolytic shock treated successfully by the Hesse-Filatov method. Symptoms of shock developed in the first case nine minutes after the infusion of 100 cc. of incompatible blood. The biologic test of Oehlecker was negative. In the second case a severe hemolytic shock developed in a person belonging to group A thirty minutes after transfusion of blood from a universal donor. The biologic test was likewise negative. In the third case, transfusion of a patient bleeding into the peritoneal cavity was done partly with her own hemolyzed blood removed from the peritoneal cavity. The symptoms developed forty-eight hours later and manifested themselves principally as those of a severe nephropathy. Transfusion with compatible blood as recommended by Hesse and Filatov, resulted in prompt cure of the three patients.

Actinocardiogram in Mitral Defects—Heckmann records the volume changes of the heart during pulsation by utilizing the changes in density on the roentgen screen for the direction of the current of a photo-electric cell. This current is intensified by a three-step low frequency amplifier and operates a mirror galvanometer, which in turn records a pulsation curve. The author designates this method as the actinocardiogram. In this report he describes curves that he obtained in patients with mitral defects. He found that in these patients the curve is characterized by a systolic increase in volume (inverse type) with subsequent steplike decrease, slight changes in volume, slight or missing diastolic increase in volume and deep auricular depression in the curve. He explains these manifestations by the enlargement of the left auricle, the fact that the systolic filling of the auricle is thus more pronounced (partial compensation for the ventricular reduction in size), the reduced inflow of blood into the left auricle during the diastole in mitral stenosis, the systolic backflow from the left ventricle into the left auricle, and finally the backflow of blood from the left auricle into the pulmonary veins.

Treatment of Thrombopenic Purpura—Klima shows that none of the various treatments of thrombopenia have been entirely successful and that the most effective method, splenectomy, involves considerable danger. For this reason, efforts have been made to improve the internal methods of treatment. In the course of investigations on the action of epinephrine, the author found that the administration of kephrine hydrochloride (methylaminoacetatechol hydrochloride) produced favorable results. He demonstrates the favorable therapeutic effects on the clinical histories of nine patients with thrombopenic purpura. He says that in injecting the substance the formation of hematomas can be avoided by giving the injection deeply on the fascia or, still better, intramuscularly. The substance is not given intravenously. However, it was found that it is also effective when given by mouth. For cases in which the hemorrhages are not severe, the author recommends the oral administration of 5 or 10 cc. of a 5 per cent solution of kephrine hydrochloride from three to six times each day. In cases of severe hemorrhage he gives deep subcutaneous or intramuscular injections of 2 cc. of a 0.5 per cent solution two or three times daily. Oral and injection therapy may be combined if it seems desirable. The hemostyptic action becomes noticeable gradually in the course of twenty-four or forty-eight hours. After the desired result has been obtained, the dose is gradually decreased. In discussing the mechanism of the therapy, the author suggests that kephrine hydrochloride induces reparative processes on the vessels, which in turn effect an increase in the number of thrombocytes.

Infection of Reticulocytes by Plasmodium Malariae—Jacobsthal found that a modification of Hirschfeld's simple method for the staining of reticulocytes (abstracted in THE JOURNAL, Nov. 23, 1935) is also suitable for the demonstration of malarial parasites. He, too, resorts to preliminary staining with Löffler's methylene blue (from two to five minutes). After careful rinsing with water there follows from five to fifteen minutes staining with diluted Giemsa solution, then rinsing with distilled water and air drying. The fixation following the Löffler staining can be done with saturated aqueous solution of mercuric bichloride. In using this method of staining in the examination of malarial blood the author found that in a new malarial infection with Plasmodium vivax or falciparum the reticulocytes are chiefly infected not the mature erythrocytes. This selective infection goes to such an extent that from 90 to 98 per cent of the infected cells are reticulocytes. The fact

that the parasites attack chiefly the young cells has considerable clinical importance. Since some of the infected cells are destroyed, the inadequate supply of young cells produces an anemia. Whereas the reticulum of the noninfected reticulocytes shows a grayish blue with this method of staining the infected reticulocytes show a much looser reticulum that is reddish. The protoplasm of the infected reticulocytes likewise appears of a delicate rose shade, in contradistinction to the complete lack of stain in that of the normocytes. In reticulocytes, which contain gametes or dividing forms, the reticulum appears in a rather compact form at the edge of the cell. The author says that the best results are obtained with fresh specimens. In preparations that have been stored for two or three days, the staining of the reticulocytes is poor.

Treatment of Eclampsia with Thyroxine—Bonilla and Goebel, after citing the reasons why thyroxine was introduced in the treatment of eclampsia, call attention to the contradictory results obtained by the various authors. These contradictions induced the authors to study the antagonism between the thyroid and the posterior lobe of the hypophysis in animals, in the hope of developing a foundation for the treatment of eclampsia with thyroid extract. They succeeded in producing in white mice, by the administration of solution of posterior pituitary, an intoxication which is characterized by collapse, convulsions and Cheyne-Stokes respiration. This intoxication could not be counteracted by thyroxine. Animals in which hyperthyroidism had been induced were extremely sensitive to solution of posterior pituitary. They died a short time after administration of 15 Voegtlin units, whereas normal animals remained uninfluenced by this dose. The authors believe that this hypersensitivity explains the failure of thyroxine in the treatment of those pregnancy toxicoses in which the increase in blood pressure predominates. The efficacy of the thyroxine in the other cases is explained by the diuretic action of thyroxine and concerns chiefly those cases of eclampsia in which the nephropathy predominates. The increased resistance to thyroxine that exists during pregnancy has not been fully explained as yet.

Protective Plastic for Cornea—Brecher shows that in a group of disorders of the cornea, such as keratitis from lagophthalmos, dysesthesias of the cornea, the nasociliary syndrome of Charlin and neurotrophic ulcerations, it often becomes necessary for the practitioner to provide a protection for the injured corneal epithelium. In cases in which the simple occlusive bandage is inadequate, blepharorrhaphy or a conjunctival flap covering is generally resorted to. However, these surgical interventions are somewhat difficult particularly for the practitioner. The author found that the shell membrane of the bird's egg constitutes an ideal material for a protective membrane for the corneal tissue. Owing to its animal origin and its other characteristics it combines in itself all the osmotic and mitosis promoting effects of the conjunctival flap covering and thus represents an entirely satisfactory substitute for it. The technic is bloodless and simple. A properly shaped piece of the shell membrane is placed for fifteen minutes in a disinfectant solution (chloramine) and is then placed on the slightly anesthetized cornea and fastened. The membrane remains in place for six or eight days or longer and after that can be easily removed.

- Treatment of Syphilis and Gonorrhea with Artificially Produced Fever W M Simpson—p 817

Mode of Life of Nonagenarians—Freund states that for a number of years he made inquiries regarding the mode of life between 75 and 100. He obtained detailed information from about 100 such persons from all walks of life. A regularity in factors, often regarded as important for longevity, is missing in this material. For instance, only two persons report that they belong to a long-lived family, whereas a large number report that they lost their parents early. The assumption of an especially healthy constitution likewise is not proved by these data, for many of the persons report serious disorders during their earlier life (tuberculosis, articular disorders and so on), others report occasional attacks of biliary disorders, rheumatism, influenza, dysentery and even serious surgical interventions and pneumonia. A care-free life cannot be considered the cause of the longevity for many reported great physical and mental exertion and times and conditions of great stress. All adhered to a mixed diet. Strict vegetarianism as well as the consumption of large amounts of meat was reported by none of these long-lived persons. Preference for a fat diet was rare, and those few who did take such a diet also ate generous amounts of green vegetables and fresh fruits. Many ate meat only two or three times each week. Foods prepared with milk were favored evening meals. Apples, oranges, tea and milk were for some a part of the daily diet. Many stress careful chewing of the foods. Rest or exercise after meals is evaluated variously. An important factor seems to be the temperament, and particularly the manner in which these persons react to unpleasant happenings. Only one of all the long-lived persons admitted a certain irritability, but even this person says that the psychic equilibrium is always quickly reestablished.

- Further Experiences with Large Doses of Atropine in Treatment of Parkinsonism S Muntner—p 850
- Treatment of Intestinal Helminthiasis During Childhood O Chiari—p 852

Roentgen Irradiation in Absolute Glaucoma—Following a review of the literature on the use of roentgen rays in glaucoma, Kreibitz says that at the roentgen institute of the Vienna general hospital roentgen treatment is given with repeated small doses. At intervals of two or three days 50 roentgens is administered until a total of 150 roentgens has been reached. After that the treatment is interrupted for one or two weeks and then further series are administered according to need. This method of treatment never caused injurious results. In a considerable number of cases the roentgen therapy proved beneficial in that it reduced the pain. However, there was no essential reduction in the intra-ocular pressure, although other investigators have observed a reduction after roentgen treatment. To be sure, occasionally the author found slight reductions in pressure, but they were not sufficient to explain the efficacy of the roentgen rays. He therefore is inclined to agree with Hensen and Schäfer, who ascribe the efficacy of the roentgen therapy to the fact that the rays render the eye insensible. After giving short histories of a number of glaucoma cases in which roentgen treatment was employed, the author concludes that a trial with roentgen therapy is justified in all painful cases of absolute glaucoma. He admits that the treatment fails in some cases but also emphasizes that patience is necessary, for frequently the improvement does not become noticeable until six or more irradiations have been applied.

Pylorospasm During Childhood—Eberle mentions the theories advanced regarding the etiology of pylorospasm and points out that it is not fully explained as yet. After describing the symptomatology, he shows that the prolonged vomiting produces, in addition to other disturbances, also a severe metabolic disorder. There is exsiccosis with inspissation of the blood and albuminuria, also chloropemia with achloruria and hypochloremia. In discussing the therapy of pylorospasm, the author says that roentgen treatment has been abandoned. Then he mentions the various medicaments that have been tried, such as papaverine and atropine. The favorable reports of other clinics induced his clinic to try a scopolamine preparation. After overcoming the comatose condition by careful treatment with sodium chloride, the treatment was continued with sodium chloride and the scopolamine preparation. Under the influence of this treatment the vomiting ceased rapidly. The author says that the new internal treatment of pylorospasm stresses the following point: Pylorospasm should be treated in a hospital. The food intake should be under strict control. There should be frequent feedings with small, concentrated portions. The child should be under the care of a conscientious nurse. The formerly employed gastric irrigations are inadvisable, because they lead to further depletion of the chloride reserves. The loss of chlorides and water is compensated by the frequent small feedings. In giving his attention to the surgical treatment of pylorospasm, the author says that the new Weber-Ramstedt method is the best. He considers surgery indicated when careful internal treatment fails. Following the operation, feeding must again be carefully supervised, for if this is not done alimentary intoxication may result.

- *Indications for Borderline Ray Therapy in Dermatology H Fuhs—p 656
- Curative Phases in Pressure Therapy of Varicose Ulcers. R Goldman—p 660
- Experiences with Alopecia Areata. A Jordan—p 662

Influence of Arsphenamine Exanthems on Syphilis—Buschke and his associates point out that, if syphilis is accompanied by severe involvement of the skin, the late processes (on internal organs and nervous system) are much milder than in patients in whom the skin is only slightly involved. A strong reactivity of the skin suggests a vigorous formation of antibodies, for it is known that the majority of infectious diseases which are characterized by severe involvement of the skin (dermatophy), such as scarlet fever, measles, rubella, smallpox and chickenpox, produce the longest lasting immunity. The involvement of the skin in the defense mechanism against syphilis engaged the attention of physicians as far back as the fifteenth century. Then it was believed that syphilis should not be treated too early so as not to drive it into the body. The leading syphilologists of the mercury era likewise advised the postponement of treatment until the exanthem had completely developed but, since the introduction of arsphenamine, early treatment has been recommended. Recently, however, the one-sided chemotherapeutic treatment has again been criticized as resulting in the weakening of the defense powers of the organism and it has been suggested that the biologic therapeutic methods be employed at least as auxiliary measures. That intense and prolonged cutaneous irritation increases the curative action of specific remedies is indicated by observations on treatment by inunction, for mercury inunctions were especially effective when they caused irritation of the skin. Further the authors mention Buschke and Freymann's observations on ten patients with arsphenamine dermatitis, all except one of whom had a negative Wassermann reaction in spite of inadequate treatment. These effects of arsphenamine dermatitis were subsequently corroborated by others but there were also some who made contradictory observations, namely, that severe arsphenamine exanthems reduced rather than increased the defense powers of the organism. However, the latter observations are by far in the minority. In discussing the mode of action of the arsphenamine exanthem on the course of syphilis, the authors suggest that allergic conditions, on the basis of a previous sensitization,

play an important part, for it is known that allergic conditions may result in immunity. They mention analogous observations, such as the cure of a case of migraine after a phenobarbital exanthem, of pemphigus after an arsphenamine exanthem, of lupus or of psoriasis after gold erythrodermia, or of lupus after bismuth dermatitis. These examples prove also that the medicaments which elicit the dermatitis are not important. The severity of the exanthem and its duration, however, seem to be essential, for, whereas in the superficial skin changes (erythemas) there is usually no effect, the cutaneous disorders which involve the "skin parenchyma," that is, the papillary body, including the epithelium and the connective tissue, usually exert an influence. The authors point out that the favorable effect exerted by arsphenamine dermatitis on the course of syphilis corroborates the opinion that ascribes to the skin an important function in the defense of the organism against chronic infection. They state that measures which promote the cutaneous reactivity are a valuable aid in the treatment of syphilis and consider it unfortunate that, for instance, mercury injections have been neglected since the introduction of the injection therapy. They recommend that mercury injections be combined with the arsphenamine therapy and that they be used instead of the mercury and bismuth injections.

Borderline Ray Therapy in Dermatology—Fuhs says that, within the range of the doses of rays which have been found adequate for the majority of dermatoses, the therapeutic use of Bucky's soft rays, the so-called borderline rays, no longer needs to be feared. In order to avoid cosmetic impairments (telangiectasias, atrophies and pigmentation disturbances) a certain maximal dose per field should not be exceeded. Moreover, the intervals between treatments and the number of exposures should likewise be carefully watched. The author generally used the same technic as to half-layer value, voltage, number of milliamperes and focus-skin distance and varied only the quantity of rays (dose). His experiences with the general application of borderline rays were practically negative in that he observed not a single convincing result. However, with the focal or local application of these rays he obtained favorable results in many dermatologic disorders. In acne varioliformis, particularly in refractory and relapsing form, a few applications of borderline rays (250 roentgens per field) are frequently successful. In angioma cavernosum, particularly in the nonulcerated, cutaneous tumors, borderline rays in doses of from 1,000 to 1,200 roentgens are often effective. The author discusses the value of borderline rays in angulus infectiosus, in multiple carcinoids of the skin and in clavus plantaris. Then he takes up dermatitis and eczema, showing that the borderline rays can be used as an auxiliary treatment in some of the subacute and chronic forms of these dermatoses. Since the borderline rays have no epilatory effect, they are especially valuable in case of eczema of the hair-covered part of the head. The author discusses the use of borderline rays in furunculosis, hidrosadenitis axillaris and Darier's disease. About nevus flammeus he says that those nevi which disappear partly or completely in response to glass pressure often yield to treatment with borderline rays (from 900 to 1,200 roentgens at intervals of from five to six weeks). The cosmetic results of the treatment with borderline rays are more favorable than those of any other treatment of nevus flammeus. Other skin disorders in which the author resorted to treatment with borderline rays are pityriasis lichenoides chronica, pruritus of the anus and of the vulva, psoriasis vulgaris, verrucae planae juveniles and finally the various forms of tuberculosis of the skin.

Role of Pituitary in Carbohydrate Metabolism—Salitowna describes the case of a woman aged 42, who suffered from diabetes and symptoms of acromegaly. She did not com-

plain of headache or eye trouble. For two and a half years she came to the clinic often for periods of from three to six weeks for observation for diabetes. Instability, changes in vision and resistance to insulin were observed each time. She was treated with roentgen rays, and some general improvement was noted in that the acromegalic symptoms were reduced. The range of vision became stabilized and her resistance to insulin was decreased. The hyperglycemia was 0.38 per cent, glycosuria was up to 250 Gm., and there were acetone bodies in the twenty-four hour urine. Inquiry determined that the diabetes had developed several years after the acromegalic symptoms appeared. Even though from 30 to 60 units of insulin was administered, the quantity of sugar stayed at the level of from 0.23 to 0.25 per cent, and even with the diet of 200 Gm of carbohydrates, the glycosuria was not less than 150 Gm. A second characteristic to be noted was a tendency to acidosis which did not allow a decrease in the quantity of carbohydrates in the diet below 200 Gm. The same applied to insulin which could not be reduced to less than 60 units during the twenty-four hours. Simultaneously there was a tendency to retain water under the influence of the insulin dosage, so that the body weight increased from 1 to 15 Kg a day. It was noted that under the influence of roentgen rays, resistance to insulin was reduced so that from 60 to 80 units was tolerated with 50 Gm. of carbohydrates in a diet of 130 Gm of carbohydrates, and after four series of roentgen rays of 4,000 roentgens each there was tolerance of from 160 to 200 Gm of carbohydrates in diet containing 305 Gm of carbohydrate, that is, the insulin indicator reached from 0.9-1.5 to 2-2.5. The patient's general condition rapidly improved. She gained 12 Kg., the signs of acromegaly diminished and her general appearance and range of vision after the second series of roentgen rays were better.

Influence of Freezing on Vitamin C content of Orange Juice and Milk—In studies on the biologic effects of vitamin C on the teeth and jaw-bones of guinea-pigs, Lilleengen ascertained the effect of freezing on the vitamin C of orange juice and cow's milk. It was found that by freezing and storing fresh orange juice and fresh winter milk at minus 30 C. for about four weeks, the biologic vitamin C effect of the orange juice decreased by slightly less than one third and that of milk by about one third.

Etiology of Pylorospasm—Halbertsma regards pylorospasm as a syndrome of spasm, tumor formation and vomiting which is a sequel of a congenital deformity. The mucous membrane canal is from the beginning too long and narrow. During the first three weeks of life the lumen is still wide enough for the passage of the relatively small quantities of food but when larger quantities are needed the passage becomes impaired. As a reaction to this disordered passage a muscular tumor may develop within a few weeks. The author points out that this theory of the genesis of pylorospasm is supported by the roentgenologic and clinical observations of various authors and by a number of his own observations. In a relapse operation he observed that the pyloric tumor had become greatly enlarged in the course of five weeks. Among the thirty-two cases of pylorospasm that were observed by him he noted that in three families the disorder recurred several times (seven children in all). Two of these families are of especial interest because they are related. The author shows a diagram of their genealogical tree and asserts that it is probable that the disorder had been present also in the preceding generation. In binocular twins, the disorder occurs with the same frequency as in other siblings. In uniovular twins, pylorospasm is present in both. The author concludes that pylorospasm is probably a congenital hereditary deformity.

CARCINOMA OF THE CERVICAL STUMP

LEWIS C. SCHEFFEY, M.D.
PHILADELPHIA

A study of the incidence of carcinoma in the cervix after supravaginal hysterectomy, widely known as "carcinoma of the cervical stump," naturally includes the consideration of certain associated problems

One of these is to ascertain how often carcinoma is found or develops in the cervical stump. The combined published reports of others may be noted as well as the cases occurring under one's own observation

A second problem is whether the carcinoma of the cervix was overlooked at the time of the hysterectomy or whether it developed sometime afterward, and what treatment has to offer

A third problem, and the one of greatest importance, is How may this unfortunate complication be avoided?

INCIDENCE OF CARCINOMA OF THE CERVICAL STUMP

It is difficult to estimate the incidence of carcinoma of the cervical stump correctly. Unreported cases, diagnostic errors and different conceptions of what constitutes the condition influence statistics. Von Graff¹ in 1934 reported an average incidence of 4.1 per cent, based on a collection from the literature of 176 cases among 4,269 patients with carcinoma of the cervix, in whom the incidence observed by different individuals ranged from 2.5 to 11.3 per cent. Richardson² believes that the incidence does not exceed 3 per cent, all factors considered. Kretschmar and Gardiner³ found eighteen cases among 1,022 patients with cervical carcinoma during a thirty year period, 1.76 per cent.

From Sept 1, 1921, to Sept 1, 1935, there were 5,433 admissions (bed capacity of twenty-seven) in the gynecologic ward service of Dr Brooke M. Anspach at the Jefferson Medical College Hospital. Of these patients 273 had carcinoma of the cervix, an incidence of 5.02 per cent of all gynecologic admissions (table 1).

During the same period ten patients with carcinoma of the cervical stump were observed, an incidence of

3.66 per cent of all patients admitted with cervical carcinoma (table 2). This represents 0.183 per cent of all gynecologic admissions.

The frequency with which carcinoma develops in the cervical stump can be determined with only relative accuracy. A follow-up study of consecutive cases of supravaginal hysterectomy in a hospital service is essential. Obviously such a review is beset with difficulties because many patients escape consistent postoperative observation and cannot be "followed up" indefinitely.

Von Graff¹ reported an incidence of 0.62 per cent in 7,244 cases collected from the literature. Richardson² is authority for the statement that the incidence is a little less than 1 per cent, basing this figure on "approximately 10,000 subtotal hysterectomies reported by a dozen different authors." More recently Fahndrich⁴ reported an incidence of a little less than 0.04 per cent. This figure was arrived at from a compilation of reports from the German literature of 7,029 supravaginal hysterectomies in which twenty-eight stump carcinomas developed (0.039 per cent), together with 11,110 similar operations collected from literature foreign to Germany in which thirty-nine stump carcinomas occurred (0.038 per cent). Pearse⁵ presents statistics from various sources totaling 13,507 cases with a record of fifty-three stump carcinomas, 0.039 per cent.

To ascertain the incidence of carcinoma of the cervical stump occurring after supravaginal hysterectomy in our gynecologic ward service, a study of its frequency has been undertaken, based on a follow-up study of the surgical cases.

From Sept 1, 1921, to Sept 1, 1935, 697 supravaginal hysterectomies were performed. Approximately one third of these patients had uncomplicated fibromyomas, one third exhibited complicating pelvic lesions in addition, generally of an inflammatory nature, while one third suffered from chronic pelvic inflammatory disease or allied adnexal conditions. Excluded from the study are fourteen postoperative deaths occurring within two weeks of operation (an immediate mortality for the series of 2 per cent), one death that occurred in the ward three months after operation (increasing the mortality to 2.29 per cent), one patient with advanced chorionepithelioma, already presenting metastases when operated on, who was discharged from the hospital in due time but returned and died of further metastases three months later. The study therefore includes 681 patients who survived the immediate operative procedure (table 3).

Of the 681 patients, 554 (81.3 per cent) have been observed at some time since the operation, and 127 (18.6 per cent) are regarded as "lost." Of these 554

patients, carcinoma of the cervical stump is known to have developed in five, an incidence of 0.902 per cent (table 4)

The majority have been examined by members of the operating staff in a specially designated "postoperative follow-up clinic." During earlier years postoperative patients were seen by the regular "outpatient" personnel. The condition of others has been reported to us by the family physician. Contact with some has been by letter. The period of observation has ranged

from only three months in some instances to twelve and thirteen years in others. The inadequacy of the follow up in many instances is frankly acknowledged.

EXPERIENCE WITH CARCINOMA OF THE CERVICAL STUMP

The question now arises: What proportion of cervical stump carcinomas were overlooked at the time of operation and what proportion were not apparent until a considerable time afterward? A review should include all the patients observed rather than a selected group of cases, e. g., one based on an arbitrary time limit between the supravaginal hysterectomy and the recognition of the disease. Some consider the lapse of one year as being indicative of the development of an independent neoplasm, others select two or three years as the limit. Such an arbitrary division may prove fallacious for several reasons. Frequently no description of the cervix at the time of the supravaginal hysterectomy is available. Only by biopsy or amputation can the actual presence of carcinoma be proved, and it is only by meticulous inspection that attention will be called to suspicious areas requiring biopsy. This is especially true of a seemingly intact cervix. Furthermore, how can it be proved that carcinoma might not develop within the time limit prescribed by some, not actually having been present at the time of operation, and its further development been so insidious that it was not recognized for several years thereafter? Definite proof of an overlooked carcinoma in the cervical canal (or cervix) is always afforded if the removed uterus or a portion of it shows evidence of a similar type of growth, especially near the site of the supravaginal amputation.

Of the five patients in whom carcinoma of the cervical stump is known to have developed, four were treated in the service and are included among the group of ten patients observed. The fifth patient was observed and treated elsewhere. Considering the group in its entirety, certain distinctive features may be mentioned. All were married, two were nulliparous (20 per cent), four were Negroes. Of the six white patients, one was Jewish. The average age was 46; the oldest was 67 and the youngest 32; four were under 40.

Five patients had the hysterectomy because of fibromyomas, complicated in two instances by pelvic inflammatory disease, two had ovarian cystadenomas, one papillary in type, two had pelvic inflammatory disease. One operation was for the interruption of pregnancy in a tuberculous patient.

In two patients the histologic diagnosis was adenocarcinoma, in eight, squamous cell carcinoma of varying degrees of malignancy.

In three patients carcinoma was probably present and overlooked at operation, in two patients this was possibly true, in five the condition was observed from six to twenty-one years afterward (table 5). The study of the individual patients, characteristically grouped, with brief abstracts of each history and a critical analysis of each case, follows.

Group 1. In three cases it is very probable that carcinoma was present and overlooked at the time of the original operation.

CASE 1.—A Negress, aged 54, a primipara, was admitted March 14, 1922, because of postmenopausal bleeding. A diagnosis of fibromyoma uteri was made, the cervix appearing to be intact. Grossly, preliminary curettage did not suggest a malignant condition, and supravaginal hysterectomy with bilateral salpingo oophorectomy and appendectomy was immediately performed. The pathologic report was "chronic endometritis with a marked hyperplasia of the epithelium, probably becoming carcinomatous." The patient was readmitted eleven months later because of pain and a bloody vaginal discharge, which had begun seven months after operation. The cervix was enlarged, indurated and friable (class 3 Schmitz, class 4, stage C, American College of Surgeons). Biopsy revealed adenocarcinoma. Radium treatment (3,100 mg. hours) was followed by death in six months.

We were to blame in this instance. In the light of present knowledge the original slide of the removed uterus has been reviewed, with this result: "The marked epithelial change should be considered malignant, areas

TABLE 3—Material for Study Supravaginal Hysterectomy

showing a transitional type of cell suggest a cervical lesion, but this is not definite." It is impossible to state definitely whether this lesion was primarily in the endometrium or in the cervical canal. Dependence on the gross appearance of the curettings was inadequate. More careful preliminary study would have resulted in a different plan of treatment. In addition, the follow up was faulty.

CASE 2.—A white woman aged 43, married, a septipara, was admitted June 11, 1928, with vaginal bleeding and discharge following a supravaginal hysterectomy performed elsewhere two months before without preliminary vaginal technique. Examination of the removed uterus was reported as carcinoma of the uterus extending from the cervix. Examination of the

a fixed, indurated and friable cervical stump that bled freely (class 3, Schmitz, class 4, stage C, American College of Surgeons) Biopsy revealed squamous cell carcinoma (intermediate grade) Radium treatment (4,400 mg hours) was followed by roentgen therapy (800 roentgens) two months later The patient is living and well eight years after the treatment

In this case proper preliminary study would have disclosed cancer of the cervix, and the initial plan of treatment would surely not have been supravaginal hysterectomy

CASE 3—A Negress, aged 31, married, a nullipara, was admitted March 23, 1931, because of pelvic pain and menorrhagia. A diagnosis was made of fibromyoma uteri accompanied by chronic adnexal inflammation Chronic endocervicitis was observed Following preliminary dilation and curettage, supravaginal hysteromyomectomy and right salpingo-oophorectomy was performed Examination of the removed organs showed no malignant growth Eight months later the patient was readmitted because of severe abdominal pain and leukorrheal discharge The cervix at this time showed a localized hyperemic and hypertrophied area on the anterior lip, but the lesion was not treated and a biopsy was not taken Intestinal obstruction was diagnosed, confirmed and relieved by operation. A recommendation that the cervix be cauterized was carried out later in the follow-up clinic. This resulted in an unusually persistent slough, accompanied by prolonged bloody discharge A biopsy now revealed squamous cell carcinoma (low grade) Clinically the lesion was comparatively early (class 1, Schmitz, class 4, stage A, American College of Surgeons) Radium treatment (2,100 mg hours) was followed by a severe local reaction with pelvic cellulitis, six months later roentgen therapy (1,512 roentgens) was administered The patient is living and well four years after treatment

It is not clear why the chronic endocervicitis noted at the time of the first operation was not treated or a biopsy was not taken Failure to do so at the time of the second admission may be excused because an acute abdominal condition was present At the time of the cauterization in the follow-up clinic, however, biopsy should have been performed, the delay in applying proper treatment need not have occurred

Group 2 In two cases, while questionable, it is quite possible that carcinoma was overlooked at the time of the original operation

CASE 1—A white woman, aged 33, married, a secundipara was admitted Sept 19, 1925, because of progressive abdominal enlargement and dyspnea A diagnosis of bilateral ovarian tumors with ascites was confirmed at operation, when supravaginal hysterectomy and bilateral salpingo-oophorectomy were performed The cervix was not inspected and preliminary dilation and curettage was not carried out While no areas of malignancy were demonstrated either in the removed papillary ovarian cysts or in the uterus, high voltage roentgen therapy (800 roentgens) was administered postoperatively Six months later "spotting" occurred and continued intermittently for three years when her occasional visits to the outpatient department ceased During this time little attention had been paid to this occasional bloody discharge, in fact one dispensary assistant told her that it was of no consequence. A year later, three and one half years after the primary operation, she was readmitted because of a vaginal hemorrhage. Examination showed the cervix to be replaced by an everting ulcerating mass, with marked peripheral induration (class 3 Schmitz, class 4 stage C, American College of Surgeons) Biopsy revealed squamous cell carcinoma (high grade) Radium was applied on two occasions (3,600 mg hours and 2,400 mg hours respectively) with subsequent roentgen therapy (2,052 roentgens) Death occurred one year and four months after the initial irradiation

While the tendency to tumor formation as evidenced by the development of papillary ovarian cysts in this patient may have been reflected in a cervix exhibiting low resistance to carcinoma, the latter was in all proba-

bility developing while the patient was a postoperative visitor to the outpatient department Because of negligence, valuable time was lost in discovering and treating this woman before the disease had reached an advanced stage

CASE 2—A Negress, aged 32, married a nullipara, was admitted Nov 15, 1926 because of menorrhagia A diagnosis of fibromyoma uteri of huge proportions, with adherent adnexa, was made A nulliparous cervix was noted as being "somewhat increased in size and softened" Preliminary dilation and curettage was performed, but the cervix was not treated in any way and a biopsy was not taken Supravaginal hysteromyomectomy and bilateral salpingo-oophorectomy were performed with some difficulty because of the size of the tumor and the accompanying adhesions. Examination of all removed tissues showed no evidence of a malignant condition The patient was readmitted three years later, saying that vaginal bleeding had begun nine months after the operation but that she did nothing about it for two years, when she went to another institution, where a diagnosis of carcinoma of the cervix was made and roentgen therapy was administered (1,800 roentgens) Examination showed the cervical stump to be enlarged, indurated, friable and partially fixed (class 5, Schmitz, class 4 and 5, American College of Surgeons) Biopsy showed a squamous cell carcinoma (high grade) Treatment with radium (3,600 mg hours) was followed by a rectovaginal fistula within a year, death occurring within a few months of her admission to the institution in which she had previously been treated, where further roentgen treatments (5,700 roentgens) were administered.

TABLE 5—Carcinoma of the Cervical Stump

| | |
|--|----|
| Patients seen | 10 |
| Nulliparas | 2 |
| Jewish | 1 |
| Hysterectomy for fibromyomas | 5 |
| Adenocarcinoma | 2 |
| Probably present at operation | 3 |
| Possibly present at operation | 2 |
| Apparent 6 to 21 years after operation | 6 |

Although the cervix in this instance was nulliparous, the notation that it was "somewhat increased in size and softened" should have called for more minute investigation The size and character of the tumor together with its fixation undoubtedly dominated the situation to such an extent that an inconspicuous cervical lesion may have been overlooked The patient's statement regarding the appearance of vaginal bleeding nine months later is the only evidence available for evaluation, since two years elapsed before she sought medical advice

Group 3 In five cases the condition was not apparent for a considerable time after the original operation

CASE 1—A Jewish woman, aged 38, married, a quintipara was admitted Aug 12 1928 because of vaginal bleeding of one year's duration Supravaginal hysterectomy with a three months fetus in utero had been performed elsewhere six years before, because of active pulmonary tuberculosis The adnexa had been conserved, no notes were available regarding the condition of the cervix Examination showed a proliferative, friable cervical growth bleeding readily (class 3, Schmitz, class 4, stage B, American College of Surgeons) Biopsy revealed squamous cell carcinoma (intermediate grade) Radium treatment (3,375 mg hours) was administered The patient is living and well eight years after treatment

CASE 2—A white woman aged 44, married, a primipara, was admitted May 11 1934, because of vaginal bleeding and a foul discharge Supravaginal hysterectomy and bilateral salpingo-oophorectomy because of an ovarian cystadenoma (nonmalignant) had been performed elsewhere, apparently not preceded by dilation and curettage or cervical treatment With the onset of bleeding seven years later the patient returned to the same operator who took a biopsy of the lesion, which revealed

adenocarcinoma, presumably of the cervical canal. Radium was applied (2,400 mg hours). Examination on admission evidenced a contracted vagina, the cervix was replaced by an ulcerative crater with marked, peripheral induration (class 5, Schmitz, class 4 and 5, American College of Surgeons). Biopsy yielded necrotic degenerated tissue, but a review of the former histologic slide substantiated the diagnosis of adenocarcinoma. Roentgen therapy (1,581 roentgens) was administered, a rectovaginal fistula developing within three months. Death occurred in another institution a month after that.

CASE 3—A Negress, aged 48, married, a tertipara, was admitted May 3, 1925, because of pelvic pain and vaginal bleeding. Supravaginal hysteromyomectomy for myoma uteri had been performed elsewhere nine years before, no notes regarding the condition of the cervix were available. Examination showed an indurated, immobile cervix, not particularly friable (class 3, Schmitz, class 4, stage B, American College of Surgeons). Biopsy revealed a squamous cell carcinoma (not graded, the slide was not available for review). Radium treatment (2,400 mg hours) was followed by roentgen therapy (800 roentgens). The patient was not seen again until six years later, when she presented herself because of vaginal bleeding. An ulcerative, bleeding growth was present at the site of the cervix in the vaginal vault, encroaching on the adjacent tissues and accompanied with widespread induration of the broad ligaments. Roentgen therapy was administered (1,628 roentgens). Death occurred five months later.

CASE 4—A white woman, aged 52, married, a tertipara, was admitted July 4, 1928, because of pelvic pain and bleeding. Supravaginal hysterectomy, bilateral salpingectomy and oophorectomy had been performed elsewhere ten years before. (Dilation and curettage and appendectomy with oophorectomy had been performed at separate times prior to the hysterectomy, but no notes about the condition of the cervix were available). Examination showed a partially obliterated friable cervix, bleeding readily and accompanied with marked peripheral induration and tenderness (class 3, Schmitz, class 4, stage C, American College of Surgeons). Biopsy revealed a squamous cell carcinoma (intermediate grade). Radium treatment (3,000 mg hours) was applied. The patient is living and well eight years after treatment.

CASE 5—A white woman aged 67, widowed a primipara, was admitted Jan. 31, 1934, because of a bloody vaginal discharge. Supravaginal hysteromyomectomy for myoma uteri together with bilateral salpingo-oophorectomy had been performed elsewhere twenty-one years before. Preliminary dilation and curettage had been performed, but no notes of the condition of the cervix were obtainable. Two years prior to admission she had received a cautery treatment in another institution for the present symptoms. Examination showed the cervix to be replaced by a proliferative mass, accompanied by peripheral induration extending into the paracervical tissues (class 3, Schmitz, class 4, stage C, American College of Surgeons). Biopsy revealed squamous cell carcinoma (intermediate grade). Radium treatment (2,400 mg hours) was administered. The patient is living and well two years after treatment.

In this group the stump carcinomas were discovered six, seven, nine, ten and twenty-one years, respectively, after hysterectomy, and it is reasonable to assume that carcinoma was probably absent when operation was performed. All were multiparas and had received no cervical treatment prior to the hysterectomy. One patient was Jewish representing an unexplained racial immunity to carcinoma of the cervix. The operative procedure in one had been for an ovarian cystadenoma supposedly nonmalignant, the biopsied cervical stump revealed adenocarcinoma. Might the original lesion have been an undiscovered glandular type of malignant growth bearing some relation to the subsequent cervical canal lesion? One patient had survived for six years following the initial treatment. Might not an efficient follow up have provided further salvage? Finally, one patient received cautery treatment without biopsy two

years prior to receiving proper treatment, and has remained well for two years in spite of the earlier delay.

An abstract of the history of the patient in whom stump cancer developed and who was treated elsewhere is enlightening.

CASE 1—A white woman, aged 30, married, a quintipara was admitted April 9, 1926, because of pelvic pain and menor rhagia. Diagnosis of relaxed outlet, lacerated cervix with eversion and myomatous uterus was made. Dilation and curettage, trachelorrhaphy, anterior and posterior colporrhaphy and supravaginal hysterectomy with right salpingo-oophorectomy and appendectomy was performed. It was noted on discharge that the cervix was well healed and the cervical stump well suspended. Histologic study of the removed uterus and adnexa showed no evidence of a malignant condition (recent review of slide also), but the removed cervical tissue was either lost or overlooked, for no report regarding it could be found. Follow-up examination one year later was negative but two years after that it was learned that she had been treated elsewhere for adenocarcinoma of the cervical stump. A recurrence has been treated twice. Her present physician reports that she is well at this time, eight years after the primary treatment for carcinoma.

This case is illustrative of negligence, either in the transportation of the removed tissue to the laboratory or in indifference on the part of the laboratory personnel. It is possible that the removed cervical tissue might have revealed a malignant condition, although three years elapsed, as far as we know, before the condition of adenocarcinoma was discovered. The cervix was apparently in good condition a year after operation. In any event it seems inexcusable that the cervical tissue originally removed was never examined microscopically. A case recorded in the carcinoma clinic is similarly illustrative. Tissue from a repaired cervix had shown sufficient hyperplasia of the squamous epithelium to be regarded with suspicion. Instead of being followed up energetically she was lost sight of, only to return four years later with an advanced carcinoma of the cervix, to which she succumbed a relatively short time after receiving radiation therapy.

Contrasted with these patients is the case of an elderly patient on the roster of the carcinoma clinic whose cervix was amputated in conjunction with an application of radium to the uterine cavity for fibrosis uteri. The curettings showed no evidence of a malignant condition, but an early squamous cell carcinoma was found microscopically in the removed cervical tissue. Further radium was promptly applied to the reconstructed cervix, and the patient is alive and well ten years after treatment.

TREATMENT

Healy and Arneson⁶ and others have called attention to the difficulties encountered in treating patients with cervical stump carcinoma stressing the hazards of both surgery and radium and emphasizing the importance of sufficient external irradiation. With meticulous radiation technic, applied in masterly fashion, they have reported a five year salvage of 14 per cent based however on those patients in whom the condition had developed at least three years after the supravaginal hysterectomy—a selected group. Von Graff⁷ reported 93 per cent of five year cures in a collected series of 428 patients. The salvage figure of Meigs⁸ (for four years only) is 76 per cent. Sackett⁹ recently published

statistics from George Gray Ward's clinic showing a five year survival rate of 48.4 per cent and a ten year rate of 25 per cent, irrespective of the time elapsing between the original operation and the radiation treatment

The ten cases that I have described were treated with radiation four with radium alone, five with radium and x-rays, one with x-rays alone. Three are alive and well eight years after treatment, representing a five year salvage of 42.8 per cent. (Two of these were treated with radium only, and in one roentgen therapy was added.) One patient is alive and well four years after radium and roentgen treatment one is alive and well two years after radium treatment only. Considering the entire group, this represents a present-day salvage of 50 per cent (table 6). The absolute curability rate in carcinoma of the cervix, recently reported from the gynecologic department,⁹ was 19.2 per cent.

The radium employed was in the form of a 50 mg capsule of radium sulfate, sealed in glass within a silver capsule of 0.3 mm thickness, enclosed in turn by a brass capsule of 1 mm thickness and further screened with black rubber tubing 2 mm in thickness. This was placed in the cervical canal or in the vaginal vault crater. For distribution about the periphery of the growth, or within it, needles, each containing 12.5 mg of radium and screened with 0.3 mm of monel metal, have been employed. Protection of normal tissues has been afforded by the liberal use of gauze packing, thus increasing as far as possible the distance between the implanted radium and the surrounding parts—bladder, rectum, intestine and uninvolved vaginal walls. In addition a self-retaining catheter has been placed in the bladder as a routine procedure.

Since 1927, treatment has been directed through four ports, two anterior and two posterior, the ports varying with the size of the patient. The object is to deliver 100 per cent of the skin erythema dose into the depths of the pelvis in two weeks, by treatment on alternate days, until the saturation level is reached. Treatment is then continued two more weeks, the depth dose being kept at 100 per cent by giving sufficient treatment to overcome any deficiency sustained in the intervals between treatments. The dosage delivered through each port by this method varies from 1,400 to 2,500 roentgens. The roentgen therapy has been administered in the department of roentgenology at Jefferson under the direction of Dr Willis Manges and his associates, Dr John T. Farrell Jr and Dr Manges Smith.

AVOIDANCE OF CARCINOMA OF THE CERVICAL STUMP

The final and most important problem concerns the measures that should be taken to avoid this unfortunate complication. What are the related factors that must be considered and how may they be controlled to best advantage?

The association of fibromyomas with carcinoma of the fundus, and to a lesser extent with carcinoma of the cervix, is an observation of long standing. More recently the thought has been expressed that excessive hormone influence in the presence of fibromyomas may predispose to a malignant condition of the cervix. Most assuredly in adenocarcinoma of the endometrium, alone or accompanying a myoma, may readily extend to the cervical canal. Meigs⁷ has advanced the thought that the association of fibromyomas and sterility is indica-

tive of uterine hypoplasia and that the cervix of such a uterus may thereby be rendered less resistant to the development of cancer. It has long been recognized too that the damaged and diseased cervix, giving rise to annoying symptoms, is a responsible factor in the etiology of carcinoma. With these thoughts in mind what should be one's attitude toward the final phase of the problem?

The best treatment of any disease is prophylaxis. If this is true then one must agree with those who insist that, whenever the removal of the nonmalignant uterus is indicated, total hysterectomy should be the procedure of choice, but prophylaxis in this instance has its limitations, and in practice such a plan cannot possibly be carried out as a routine measure. The immediate safety and recovery of the patient is the primary consideration, not the possible occurrence of a remote lesion. This statement is based on the presumption that the incidence of carcinoma of the cervical stump is comparatively less than the increased mortality and morbidity resulting from complete hysterectomy as compared with the supravaginal operation in the hands of the average operator. While it is true that the majority of stump carcinomas have occurred following subtotal hysterec-

TABLE 6—Treatment

| | Patients Treated | Alive at Present | Died |
|--|------------------|--------------------|----------------|
| Radium only | 4 | 2 (8, 8 and 2 yrs) | 1 (6 mos) |
| Radium and x ray | 5 | 2 (8 and 4 yrs) | 3 (1 to 6 yrs) |
| X ray only | 1 | 0 | 1 (4 mos) |
| 5-year curability (3 patients) Living and well (5 patients) | | | 42.8% 60% |

tomy for fibromyomas, it is likewise true that the majority of uteri have been removed because of them, either alone or accompanied with adnexal lesions.

The consensus contributed to by the testimony of numerous observers studying large series of cases seems to be that in average hands the mortality following complete abdominal hysterectomy is actually greater than that which follows the subtotal operation. The recently published statistics of Siddall and Mack¹⁰ lend much support to this belief. A collected series of 4,559 total hysterectomies reveal a mortality of 3 per cent as opposed to the figure of 2.6 per cent for 7,795 subtotal procedures, to this they add their own results, 6.4 per cent for 235 complete and 2.6 per cent for 1,141 supravaginal operations.

Meigs,⁷ in establishing an incidence of 0.73 per cent for what he terms "real" cervical stump carcinoma states that this is less than half of the incidence of cervical carcinoma as observed at the Massachusetts General Hospital arguing from this fact that carcinoma of the cervical stump is only half as likely to occur in women as is carcinoma of the cervix in general. From this he deduces that "for the advocates of total hysterectomy to maintain their position it would be necessary for them to show not over a 0.73 per cent difference in mortality between subtotal and total hysterectomy."

Richardson² points out that among expert and experienced operators the mortality in either operation does not exceed 1.5 per cent, but he wisely calls attention to the fact that, apart from the question of mortality, postoperative complications and morbidity play a significant part in discouraging the adoption of complete hysterectomy as a routine procedure. While in

⁹ Scheffey L. C. and Thudium W. J. Further End Results in the Treatment of Carcinoma of the Cervix, *Am J Obst & Gynec* 31: 946 (June) 1936

¹⁰ Siddall R. S. and Mack, H. C. Subtotal versus Total Hysterectomy *Surg Gynec & Obst* 60: 102 (Jan) 1935

exceptionally skilled hands the complete operation may be performed with comparative rapidity and safety—even perhaps in the presence of a complicated pathologic condition—it is unquestionably true that it is not the average operator alone who finds it more difficult and time consuming than the supravaginal procedure, even though excellent plans, such as those proposed by Richardson¹¹ and Farrar,¹² are followed.

During the period covered by this review only thirty-seven complete hysterectomies were performed in the ward service. Twenty-two were abdominal with two postoperative deaths, both occurring in patients with fundal carcinoma, a mortality of 9.9 per cent. Fifteen

TABLE 7—Complete Hysterectomy

| Type | Number | Postoperative Deaths | Mortality |
|-----------|--------|----------------------|-----------|
| Abdominal | 22 | 2 | 9.09% |
| Vaginal | 15 | 0 | 0.00 |
| Total | 37 | 2 | 5.4% |

were vaginal with no deaths making the total mortality for the complete operation 5.4 per cent (table 7).

Considering these expressions of opinion, it does not seem rational to advocate complete hysterectomy as a routine procedure, even though endocervicitis or cervical lacerations with eversion and hypertrophy are present.

What is the best procedure that can be followed from the prophylactic standpoint in lieu of routine panhysterectomy? The answer is thorough preliminary inspection of the cervix and cervical canal, possibly utilizing Schiller's test and the colposcope, with biopsy of suspicious areas, or endometrial curettage if indicated. This plan may be criticized as time consuming. Perhaps it is, but of what moment is a matter of a delay of twenty-four or forty-eight hours if the ultimate risk to the patient's life is thereby diminished? Should the presence of a malignant condition be disclosed, the plan of treatment may then be altered accordingly.

If the results are negative, thorough cauterization of the cervical mucosa, cervical canal, everted and eroded areas on the cervical lips at the site of old lacerations, or in some instances cervical surgery, can be carried out before proceeding with abdominal section. If a prolonged or hazardous abdominal procedure is anticipated these cervical procedures may be deferred until later. If diagnostic curettage has not been performed beforehand (as is desirable in exceptionally suspicious cases), it should certainly be done at this time. If the curettings are grossly suggestive of a malignant growth a frozen section can be examined forthwith, or a capsule of radium may be placed in the uterine cavity while a twenty-four hour pathologic report is awaited. If carcinoma of the endometrium is not probable the uterine cavity may be flushed with 70 per cent alcohol injected slowly with a syringe following diagnostic curettage and cervical treatment thus sterilizing the uterine cavity prior to the hysterectomy and providing an aseptic field for the supracervical amputation.

The foregoing procedures ought not be reserved solely for the patient who is a poor surgical risk or for one in whom the pelvic pathologic condition is questionable or undoubtedly complicated. It is recommended likewise for the patient whose general physical con-

dition is good and in whom the pelvic pathologic condition is apparently well defined. The plan outlined should also be carried out even when the cervix appears to be intact. Close scrutiny may reveal an area or areas that would be benefited by cauterization and diagnostic curettage sometimes reveals unsuspected pathologic changes. When fundal carcinoma is definitely suspected a sound plan is to perform diagnostic curettage and apply radium to the uterine cavity pending the establishment of the diagnosis by microscopic study or a rapidly prepared section (not necessarily a frozen one), subsequent high voltage roentgen therapy to the pelvis is then followed by panhysterectomy in from four to six weeks, unless there are definite contraindications to radical surgery, in which event continued radiation therapy may be imperative.

If, on the other hand, with a patient in reasonably good physical condition the cervix is hypertrophied, lacerated and everted, and the examination under anesthesia leads one to believe that operation presents no unsurmountable technical difficulties, complete hysterectomy might well be considered as the procedure of choice.

The desirability of adequate follow up after this plan of treatment should be emphasized. Sometimes the cauterized cervix needs further attention even the cervix that has been treated surgically should be kept under observation at intervals. Numerous authors have called attention to the recurrence or occurrence of a malignant growth in the vaginal vault following total hysterectomy. This fact may be coupled with one that is sometimes forgotten, namely, that an operative fatality may defeat the objective of a radical procedure, designed as it is to eliminate the diseased cervix. This adds further weight to the argument of those opposed to complete hysterectomy as a routine procedure.

The plans outlined have been followed in the ward service for fifteen years. This experience has resulted in modification from time to time of technical details in the operating room. My associates and I have sought more effective cooperation with the pathologic laboratory and have developed a decidedly better follow up

TABLE 8—Preliminary Procedures Supra vaginal Hysterectomy

| Years | Number | No Dilation and Curettage or Cervical Treatment | Dilation and Curettage Only | Dilation and Curettage Cautery | Dilation and Curettage Cervical Surgery |
|-----------|--------|---|-----------------------------|--------------------------------|---|
| 1921-1925 | 293 | 15 | 108 | 0 | 25 |
| 1925-1935 | 358 | 50 | 150 | 10 | 10 |
| Total | 651 | 65 | 258 | 10 | 35 |
| Per cent | | 10.2 | 39.2 | 1.5 | 5.4 |

system. In some instances either because of the inaccessibility of the cervix or for some unexplained reason, curettage was dispensed with. Absence of lesions naturally accounts for a reduction in the number of cervixes treated.

A controversial subject is whether or not cervical cauterization coming out of the cervical mucosa either from below or from above repair or amputation will tend to prevent the development of carcinoma. It has been repeatedly pointed out that 80 per cent of cervical carcinomas develop on the portio vaginalis. Their destruction or removal or the cervical mucosa alone will not suffice. It should not be forgotten however that eversion and erosion of the cervical mucosa extending down to or involving the squamous surface is therefore at the point where carcinoma is believed to originate.

11. Richardson, J. E. H. A. S. "The Technique of the Vaginal Panhysterectomy." *Am. J. Surg.* 45: 245 (Feb.) 1925.

and that thorough treatment of this area, either by the cautery or by surgical removal, is not only a rational prophylactic measure but a curative one as well. Pemberton and Smith¹⁵ presented substantial evidence of this assumption in 1929, when they reported the occurrence of but five known cases of carcinoma following treatment of 5,692 cervixes. Tompkins¹⁶ has recently reported a follow-up study of 611 patients having cervical treatment of all varieties, of whom but two are known to have developed carcinoma.

Preliminary dilation and curettage alone was performed in 267 of the 681 patients (39.2 per cent), 169 (24.8 per cent) had cervical cauterization as well, while thirty-nine (5.7 per cent) had cervical surgery in addition to the curettage. Two hundred and six (30.2 per cent) received no preliminary curettage or cervical treatment of any kind. It is of interest to note that in the first seven years of this review these procedures were omitted 156 times in 293 operations (53.1 per cent), while in the latter seven years they were omitted but fifty times in 388 operations (12.8 per cent). This is a striking illustration of the increased importance attached to these methods. Also of interest is the fact that from 1921 to 1928 the twenty-nine cervixes that were treated were either repaired or amputated and none were cauterized, while from 1928 to 1935 but ten were treated surgically while 169 were cauterized (table 8).

TABLE 9—Incidence of Carcinoma of Cervical Stump, Treated and Untreated Cervices

| | |
|-----------------------------------|------------|
| Patients followed up | 554 |
| Cervices treated | 170 |
| Known carcinoma of cervical stump | 1 (0.508%) |
| Cervices untreated | 384 |
| Known carcinoma of cervical stump | 4 (1.04%) |

Only one of 170 patients out of the 554 who received cervical treatment prior to hysterectomy is known to have developed stump carcinoma, representing an incidence of 0.508 per cent. Of 384 of the 554 patients receiving no cervical treatment, four are known to have developed stump carcinoma, an incidence of 1.04 per cent, or twice that which occurred among those who had received cervical treatment (table 9).

CONCLUSIONS

The incidence of carcinoma of the cervical stump does not justify complete hysterectomy as a routine procedure in every case.

Careful preliminary inspection, biopsy of the cervix, and diagnostic curettage will reduce to a minimum the chance of overlooking carcinoma.

A diseased cervix always requires treatment, but, when cauterization will suffice, its practice as a preliminary to supravaginal hysterectomy makes complete removal unnecessary. In a few instances, trachelectomy or trachelorrhaphy may be better than cauterization. From this review it would seem evident that those patients who did receive preliminary cervical treatment were less prone to develop carcinoma of the cervical stump.

In our experience, treatment has resulted in a curability of 42.8 per cent for five years and longer.

ABSTRACT OF DISCUSSION

DR. J. P. PRATT, Detroit. Some difficulty is experienced in arriving at the correct figure for occurrence of carcinoma in the stump of the cervix, following supravaginal hysterectomy. The figures presented from time to time show a considerable number. Correction for the true recurrence is not always easy. If there were no cervical stumps left, there could be no such recurrences. The question at hand seems to be to balance the difficulty and hazard of a complete or total hysterectomy against the hazard of carcinoma occurring in the cervical stump. There seems to be a rather wide variation in opinion concerning the relative risk of a total and a partial hysterectomy. For a number of years my choice of operation was incomplete hysterectomy because it seemed safer. The late Dr. J. F. Baldwin practiced complete removal for years with admirable results. One demonstration by him was convincing that the total removal of the uterus need not exceed the risk of partial removal. He influenced me to accept total hysterectomy as the operation of choice. Having adopted his method, I am able to corroborate his statement that total incurs no greater risk than partial hysterectomy. For several years our operative mortality has been less than 0.5 per cent. There is an irreducible minimum mortality on account of emboli and other uncontrollable conditions not characteristic of a particular operation, but suitable preoperative and postoperative care, together with the proper technique for total hysterectomy, should enable an operator competent to do a partial hysterectomy to do a complete hysterectomy, with a margin of safety far below the frequency of carcinoma in the cervical stump.

DR. HENRY SCHMITZ, Chicago. I congratulate Dr. Scheffey on the excellent and conservative way in which he has presented this subject. The subject of stump carcinoma of the cervix is of interest because one always feels that, when a carcinoma occurs in the cervical stump, primary removal of the cervix would have prevented such a catastrophe. I have assumed the conservative attitude. If the cervix on preoperative examination seems to be normal it is not necessary to remove it during hysterectomy. Unfortunately, I cannot give the percentage of stump carcinomas following hysterectomies as Dr. Scheffey did, which stamps his report as being unusually valuable. A year ago I studied 730 consecutive cases of carcinoma of the cervix observed up to Dec. 31, 1931. There was an incidence of stump carcinoma of 3.84 per cent or twenty-eight cases. Recently I studied a group of cases admitted from May 1, 1933, until June 30, 1934. In these ninety-seven cases I found nine cervix stump carcinomas, or 10 per cent. Of course, this doesn't mean anything so far as the incidence is concerned, but it is interesting to note that in the one large group we had 3.5 per cent stump cancer and in the smaller group of recent origin 10 per cent. The question arises whether these carcinomas could have been prevented by total hysterectomy. The removal of the cervix would have prevented them, but I feel that if the cervix is perfectly normal on examination there is no necessity for the removal. The cases cited were treated with radiation. They were studied carefully to determine the clinical extent of the tumors. The same observation made for primary carcinomas applies to stump cancers. The earlier the patient comes for treatment, the better are the good end results. The absolute five year curability percentage was twenty-five in our group.

DR. R. Q. ROWSE, Sioux City, Iowa. I had two subtotal hysterectomy patients return within a period of five years for carcinoma of the remaining cervix. That induced me to perfect a method of complete hysterectomy in all my cases. I have classified them in this manner: fibroid uterus and dangerous uterus; fibroid uterus in multiparas with lacerations and endocervicitis; complete hysterectomy; fibroid uterus in nulliparas aged 35 or under with normal cervix; subtotal hysterectomy, leaving tubes and ovaries. Dangerous uterus constituted by the troublesome, bleeding, retroverted uterus, usually in multiparas. There is a definite difference between menstruation and bleeding. It is the bleeding uterus that is dangerous. There were forty-two complete hysterectomies for fibroids and forty complete hysterectomies for dangerous uterus. Specimens showed seven cancers in the forty-two fibroids and seven cancers in

the forty dangerous uteri. The whole group numbered eighty-two cases. The total number of cancers found was fourteen. All patients are living. There have been no recurrences.

DR. LEWIS C. SCHEFFEY, Philadelphia. I want to congratulate Dr. Pratt on his remarkable postoperative mortality of 0.5 per cent following total hysterectomy. I did not have time in the presentation of the paper to mention some statistics that also came from Detroit which lent support to the argument that routine complete hysterectomy is inadvisable. They were reported by Siddall and Mack, who, in addition to collecting a series showing 3 per cent mortality following total as against 2.6 per cent following supravaginal hysterectomy, reported their own results, 6.4 per cent mortality following 235 complete operations and 2 per cent following 1,141 supravaginal hysterectomy. Dr. Schmitz has mentioned that the incidence of carcinoma of the cervical stump following supravaginal hysterectomy varies a great deal. I did not have time to quote the recent work of Fahndrich, who collected more than 18,000 cases of supravaginal hysterectomy, with an incidence of stump carcinoma of less than 0.04 per cent. I think that when complete hysterectomy is indicated the operative plan devised by Richardson, and the one later described by Farrar, tend to make the operation a great deal easier.

IDENTIFICATION OF THE CANCER CELL

WILLIAM CARPENTER MacCARTY, MD
ROCHESTER, MINN.

Cancer must be recognized and treated early if the best results are to be obtained. This has been the theme of all professional and popular international, national, state and county campaigns for many years.

The question arises: Are we recognizing cancer early? In 1918 I began a series of observations to determine just what effect cancer campaigns were having on the actual sizes of cancers being removed surgically. As pointed out by Balfour, Harrington and Rankin, only 25 per cent of the cancers of the stomach, 50 per cent of cancers of the breast and 58 per cent of the cancers of the large intestine are operable when seen by surgeons. These figures have not changed appreciably over a period of fourteen years. There has been little or no change in the average size or percentage of those having glandular involvement in this same period.¹

There has been certainly some improvement but it has not reached a high point comparable to the therapeutic efficiency of surgeons and radiologists, who have shown remarkable results considering the advanced stages of cancer they have been forced to treat.

So far as the pathologist is concerned, his technical methods of study of tissues have changed little if any since the time of Virchow; he still uses autopsy or other material fixed and embedded in paraffin or celloidin. He also uses predominantly only the low powers of the microscope. Medical students today rarely if ever see unfixed tissues; they get their knowledge from the same type of microscopic sections that were looked at by students forty years ago.

In 1907 I began the study of fresh, unfixed, unembedded, surgically removed tissues with and without stains. It was not very long before I recognized that cancer cells were not irregular in shape and size or even pyknotic as described in textbooks; neither did they contain asymmetrical mitotic figures described by von Hansemann² in 1890. Living and unfixed and unembedded fresh cancer cells were found to be beautifully ovoidal or spheroidal and to contain one or more large nucleoli, which are rarely visible in fixed and embedded postmortem material. It was quite obvious that the nucleoli were much larger in such malignant cells than in reparative regenerative cells with which they might be confused with low powers of the microscope. Drawings and photographs of these were shown as early as 1914 and since then measurements have been made and reported.³

Today I wish to report a recent series made by different and independent workers in our laboratories of surgical pathology. The accompanying tables should be sufficient to substantiate the repeatedly made statements that the nucleoli of cancer cells are much larger than those in any other condition of cells of a given tissue.

If this is true pathologists must study perfectly fresh tissues without embedding if they expect to recognize cancer before it reaches the late stage of

with another. Wherever the ratios have been studied the malignant cells have always large nucleoli by which they can be identified as malignant cells. The figures I have presented summarily are merely the averages. Each observer has made thousands of measurements, some of which have been published in detail and the rest of which are now in print.

In this necessarily brief report I can merely state the facts in the hope that other pathologists will take

the time to look for them under similar technical conditions. Opinions based on failure to confirm these facts in fixed tissues that are not fresh and not embedded are not only of no value but will impede progress in the early recognition of cancer which all agree is so necessary for beneficial therapeutic results.

The cancer cell has identifying characteristics. Histology of the past and present and modern cytology

are two very different sciences with quite different technics requiring a somewhat different training yet to be recognized by general pathologists and taught by them in a routine way to modern medical students.

Until medical students are taught this newer method, we cannot expect cancer to be recognized early.

ABSTRACT OF DISCUSSION

DR WILLIAM C MACCARTY, Rochester Minn. Many cells from Hodgkin's disease, lymphatic leukemia and lymphosarcoma have been studied, measured and drawn. The question was asked with regard to the Sternberg cell which in my opinion has nothing to do with Hodgkin's disease so far as its malignancy is concerned. The main cell which is malignant in Hodgkin's disease is the lymphoblastic cell and that certainly follows all rules of nucleonuclear ratios. The Sternberg cell, an endothelial cell, cannot be compared with the other cells in Hodgkin's disease. The Sternberg cell or Dorothy Reid cell, is not the important element in Hodgkin's disease. The lymphoblastic elements constitute the important one.

FEVER THERAPY IN TABES DORSALIS

RELIEF OF GASTRIC CRISES AND LIGHTNING PAINS
BY THE USE OF THE KETTERING
HYPERTHERM

A. E. BENNETT, M.D.
OMAHA

There have been many therapeutic opinions and no uniformity of agreement among men of much experience in the management of tabes dorsalis. Many authorities state that the disease tends to be progressive in spite of treatment. In the early stages many believe that the disease can be arrested and clinical cures obtained. In the late stages, the burned out seronegative phase, most reports of large series of cases are very discouraging, especially as to relief of intractable symptoms.

CHEMOTHERAPEUTIC RESULTS

The routine treatment of the tabetic patient as used by the majority of practitioners has been courses of arsphenamine, neoarsphenamine, mercury and bismuth salts with iodine therapy. These courses are kept up until the patient gives a persistent blood and spinal fluid seronegative response. Various modifications of this technic have been employed, as combined spinal drainage or added Swift-Ellis technic. In reviewing the literature it is noticeable that as various forms of fever therapy have increased the former popularity of the Swift-Ellis treatment has dwindled. Probably its benefit was solely from the febrile, aseptic meningeal reaction produced. At present it seems to be used only in isolated instances to relieve intractable pain.

Up to 1925 probably the best results obtainable in tabetic treatment by routine chemotherapy and special methods are summarized by Stokes and Shaffer.¹ Their technic consisted of vigorous treatment by arsphenamine, mercury and intravenous iodide therapy followed by Swift-Ellis injections. In 170 cases they report some relief from lightning pains in 73 per cent and excellent results in only 16 per cent, in another series

From the University of Nebraska College of Medicine, Department of Neurology and Artificial Fever Therapy Research.

Read before the Section on Nervous and Mental Diseases at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

1. Stokes, J. H. and Shaffer, L. W. Clinical Management and Response of the Tabetic Patient. J. A. M. A. 85:1271-1275 (Oct. 24) 1925.

of 124 cases, good results in 47 per cent and poor results in 52 per cent

In the relief of "stomach trouble," excellent results were obtained in 42 per cent, good results in 37 per cent of twenty-four cases. In the relief of gastric crises, 24 per cent obtained a good result, 76 per cent poor results in seventeen cases. A complete response was obtained in only two cases, amelioration in 24 per cent and no relief in 23 per cent. A good result in cord bladder was obtained in 31 per cent, poor in 69 per cent of seventy-three cases. Ataxia was relieved in only 21 per cent of sixty-three cases. Other resistant symptoms, such as paresthesia and cranial nerve palsies, were relieved in from 24 to 73 per cent in smaller groups of patients. They found good results in 48 per cent of 170 patients and summarized² "The tabetic has a 50-50 chance of securing a completely satisfactory result under systematic treatment." They added "Lightning pains may prove intractable and persist long after signs of active meningitis disappear" the notorious persistence of lightning pains after the apparent arrest of degenerative process in some cases is one of the trying features of late tabes."

O'Leary and Nelson³ in the same year found that they had relieved pains in fourteen out of twenty-two cases, gastric crises in six out of fifteen cases, although they had obtained complete negative spinal fluids. They concluded "We have nothing new to offer in the treatment of patients with negative serologic tests who suffer from persistent gastric crises other than chordotomy, which seems to hold out more hope than any form of treatment that has been offered thus far."

Because of favorable results from tryparsamide therapy in dementia paralytica, the drug has received extensive trial in tabes dorsalis. In early tabetic patients some favorable reports are to be found. Paterson-Smyth⁴ and David and Robert Lees⁵ praise tryparsamide in early cases. Most observers, however, have found the results in tabetic patients disappointing. Wile and Wieder⁶ were unable to relieve gastric crises and lightning pains with tryparsamide. Menzies⁷ concluded that the results from tryparsamide therapy in tabetic patients were very disappointing, especially in securing relief from pain. He believes that malarial therapy is far superior. All agree that tryparsamide is dangerous in the face of tabetic optic atrophy.

More recently bismuth arsphenamine sulfonate (bismarsen) has been much used experimentally in the treatment of tabetic symptoms. Hadden and Wilson⁸ improved 41 per cent of seventeen seronegative tabetic patients by forty injections. They found the drug reasonably effective in relieving pain, gastric crises, ataxia and cord bladders and considered it superior to tryparsamide. Tobias⁹ and Fong¹⁰ also reported favorable results in early tabes.

RADICAL TREATMENTS INCLUDING OPERATIVE

Numerous special methods of more radical nature have been advocated for the relief of resistant tabetic symptoms that fail to respond to routine systematic therapy. Hassin¹¹ recommended epidural arsphenamine injections and reported some relief in pain and ataxia but no relief of gastric crises. He had severe complications in three cases. This method in my experience has been dangerous, because caudal neuritis is readily produced. In isolated cases forced spinal fluid drainage, spinal anesthesia, intravenous atropine, and insulin therapy are reported to relieve patients of certain resistant symptoms. The most radical procedure for the relief of tabetic pain and crises is the operative treatment. Resection of the posterior and anterior roots has been advocated since 1900. Of late years this procedure has been replaced largely by chordotomy. Even with this procedure, relapses of pain and crises are frequent and the mortality from the operation is high. It is certainly a procedure of last choice and offers nothing certain as to relief. My own experience has been unsatisfactory.^{11a}

FEVER THERAPY IN TABES DORSALIS

Again the excellent results seen from various forms of fever therapy in dementia paralytica caused it to be employed extensively in the treatment of resistant tabetic symptoms. Isolated reports of benefit obtained by fever-producing agents such as sodoku, foreign proteins and sulfur in oil are to be found. The series of cases are too small to draw definite percentage results. Pyrifer, colon bacillus vaccine, has been popular abroad. Polozker and Altschuler¹² consider their results from its use better than from malarial therapy. They reported distinct improvements in five cases out of eight, and state that all patients obtained relief from pains.

Up to the present the most extensive experimentation in fever therapy for the relief of tabetic symptoms has been the use of malarial fever inoculation. In attempting to evaluate results we again find marked discrepancy of opinion, varying from Roger,¹³ who thinks that malarial results in tabes have not been constant enough to justify its use, to Bering¹⁴ who reports 75 to 80 per cent improvement. The following investigators have treated rather large series of patients: Hoff and Kauders,¹⁵ Dreyfus and Hanau,¹⁶ Driver, Gammel and Karnosh,¹⁷ Ebaugh¹⁸ Wile and Davenport,¹⁹ Yates,²⁰ O'Leary and Welsh,²¹ and David and Robert Lees.⁵ The percentage of improvement reported varies from 34 to 75. One can conclude fairly that

about 50 per cent of all types of tabetic patients are benefited by malarial therapy. Most observers agree that the tabetic patient is not able to stand malarial inoculation nearly as well as the parietic patient. Its use is contraindicated in advanced ataxic states or with complicated associated infectious processes such as cord bladder.

The mortality from malarial complications in tabes dorsalis is high. David and Robert Lees⁵ report 10 per cent mortality, Carrière²² 17.62 per cent. Vonderlehr,²³ listing all cases of malarial therapy in parenchymatous neurosyphilis, reported a total from 1923 to 1931 of 8,038 and found that 23.4 per cent of the patients had died. Deaths from malaria and other causes were not separated. In 123 cases, a mortality of 16.3 per cent was specifically caused by malaria. Karnosh and Williams²⁴ found 12.7 per cent mortality from malaria in 580 patients.

Neyman and Koenig²⁵ had a malarial mortality of 18 per cent in fifty parietic patients, 10 per cent from sodoku in fifty, and no mortality from diathermy in fifty. O'Leary and Welsh²¹ found a beneficial effect from malaria in about half of tabetic and taboparetic patients with a positive spinal serologic reaction. The serologic negative patients with resistant symptoms were only slightly benefited. In twelve such cases, although 22 per cent were benefited to some degree, only 1 per cent were entirely relieved.

These observations leave much to be desired in results from the malarial therapy of tabetic patients. While resistant symptoms of tabes are often strikingly relieved by malarial therapy, still the total percentage of improvement by its use is not much if any better than from systematic routine chemotherapy. In addition there is a high mortality from the direct complications of the malarial infection. In the advanced stages of tabes its use is dangerous, since the single tertian strain quickly becomes a double infection and patients are rarely able to stand more than eight paroxysms of fever. In cases in which results are needed, malaria gives the poorest relief. In early stages other less rigorous therapy will give equally good results.

Of recent years an intense research program has been under way in many centers in an effort to estimate the value of artificial fever therapy by physical means. Major evidence favors fever therapy from any source as being the effective agent in neurosyphilis. Sufficient time has not elapsed to determine the effectiveness of various forms of physical heat therapy in large series of cases. However, encouraging results are being reported. Beermin, Hirschfeld, Epstein and Paul²⁶ treated twenty tabetic patients with diathermy. They reported seventeen cases, nine of which were relieved of severe pains and crises, three were generally improved, and three unimproved. They stated "The remarkable influence of treatment upon severe crises and pain cannot be overemphasized." Nelson²⁷ reported

a small series of cases treated with low temperature diathermic treatments with striking relief of pain.

Simpson²⁸ in a recent extensive report on the use of artificial fever therapy by means of the Kettering hypertherm in syphilis found striking relief in ten cases of tabes dorsalis and seven cases of the tabetic form of dementia paralytica. He obtained relief in all cases of gastric crises and lightning pains. Of the fourteen ataxic patients, ten showed improvement in gait. Two with cord bladders were restored to normal function. Mehrtens and Pouppirt²⁹ reported that lightning pains, gastric crises and Charcot joints yielded to hot baths more readily than to any other therapy previously used.

At the University of Nebraska through the courtesy of Charles F. Kettering and Dr. Walter Simpson, we have been permitted to experiment with artificial fever therapy by the use of the Kettering hypertherm in a large variety of infectious diseases. By means of the hypertherm, or air conditioned cabinet, we are able readily and safely to develop and sustain patients' temperatures at any desired level. The technic employed in our clinic has been that advised by Simpson. In neurosyphilis we have given fifty hours of fever from 105 to 106 F. in ten sessions, combined with some form of chemotherapy. By this technic we are able to give our patients about twice as much fever as ordinarily is obtained from twelve malarial paroxysms.

The following report is limited to results obtained up to date in the treatment of tabes dorsalis in twenty-four cases at the University of Nebraska, fourteen of which have completed a prescribed course of treatment. Through the courtesy of Dr. F. G. Ebaugh we have been permitted to report six additional cases from the University of Colorado Fever Therapy Research department. The patients have all received chemotherapy with fever, the majority have received 0.2 Gm. of arsphenamine bismuth sulfonate each week at the same time at which they received five hours of artificial fever of 105 to 106 F. for a total of ten treatments, or fifty hours of fever therapy. Most of these patients had previous intensive therapy but were referred to the department because of chronic resistant symptoms.

REPORT OF CASES

Twenty-four patients with a predominantly spinal cord type of chronic syphilis have been under treatment. Twenty-three cases are tabes dorsalis, with one case of meningomyelitis. Fourteen patients have completed the prescribed course of artificial fever therapy combined with chemotherapy. Four patients discontinued treatments and six are still under treatment at the time of this report.

The ages in the fourteen completed cases varied from 33 to 58 years, the average age being 43 plus years. There were three women and eleven men. The average duration of the infection was 21.5 years. All but three patients had received previous systematic routine chemotherapy. Several patients had received additional special types of therapy directed toward symptomatic relief of intractable pains and crises. One patient had tried high voltage roentgen therapy for relief of pains, and two patients had taken courses of malarial fever therapy without relief. Two patients had received Swift-Ellis intraspinal injections and one had finally been advised to have a chordotomy performed.

The predominant resistant tabetic manifestations for which treatment was advised were lightning pains and gastric crises, and this preliminary study is directed mainly toward the problem of relieving these symptoms. All but one patient of the completed cases had been having active gastric crises or lightning pains or both symptoms at the time therapy was begun. The duration of the gastric crises and pains varied from one to fourteen years. Seven patients had suffered for periods of five years or longer. Eight of these fourteen cases were considered well advanced types of tabes dorsalis. Five patients were incapacitated at least half the time, two patients had associated morphine addiction. Eight patients had mild to severe grades of ataxia and one patient (meningomyelitis) had a spastic paraplegia. Three patients had associated cord bladders. Other associated tabetic symptoms were trophic ulcers, Charcot joints, paresthesias, optic atrophy, oculomotor palsies, undernutrition, vertigo, trigeminal neuralgia and impotence.

All patients had positive neurologic signs of tabes dorsalis, the usual triad being Argyll Robertson pupils, absent leg tendon reflexes and signs of proprioceptive dysfunction. Four cases were considered "burnt out" or seronegative spinal fluid types. Ten patients had varying degrees of positive serologic response in the blood and spinal fluids.

Eleven patients were given bismuth arsphenamine sulfonate therapy (0.2 Gm.) with each fever treatment. Nine patients received fifty hours or more of artificial fever above 105 F. Five patients received thirty hours or more above 105 F, with treatments discontinued because of complete relief of complaining symptoms. We have usually seen prompt relief in the tabetic pains after the sixth and seventh treatments, that is, from thirty to thirty-five hours of fever therapy. Twelve patients of the fourteen have remained free from gastric crises and pains from three months to one year. One patient was not having active pains at the time treatment was being given but was very ataxic, one patient has had a recurrence of pains to a mild degree, since he had taken only thirty hours of fever therapy, he was advised to return for more treatment. Five of the eight ataxic patients obtained marked improvement in ataxia, three patients showed little if any change in ataxia. The spastic patient felt stronger but there was no objective change in the paraplegia, the root pains, however, were completely relieved. Two patients with cord bladder were markedly improved and one was unimproved. Patients reported other improvement or relief, as increased general strength, gain in weight, relief of headaches or improvement in paresthesias, one each reported relief from trigeminal neuralgia and from persistent vertigo.

The reasons for discontinuing treatments in the four patients were as follows. One patient living out of the city was unable to make the trips. Two patients failed to cooperate and discontinued of their own accord. One patient displayed emotional instability, causing us to advise stopping treatment.

The patients now under treatment have not been followed sufficiently long to warrant expressing an opinion. Two have very severe types of tabes, one with coronary disease able to take only short fever sessions and another with totally disabling gastric crises unrelieved by malarial therapy, obtaining relief after the seventh fever session.

No unusual complications during treatment of our tabetic patients were observed that are not seen in

other neurosyphilitic patients. One has to watch closely for hyperpyrexia and cerebral edema while the patient is in the cabinet. We feel on the whole that the tabetic group have to be managed with greater care than the dementia paralytica group. However, our clinic has had fewer fever therapy complications in the tabetic group than with the meningovascular neurosyphilis group, in the latter, cardiovascular complications seem more frequent.

Dr F. G. Ebaugh in a personal communication has reported to me six tabetic cases that have been under artificial fever therapy at the University of Colorado. Four patients with severe intractable gastric crises and pains completed the prescribed course of fever therapy combined with tryparsamide. These four patients received forty or more hours of fever therapy and all obtained marked relief from gastric crises and pains. One patient with cord bladder was relieved and one markedly ataxic patient was improved in gait. One patient's treatments were incomplete and one had a recurrence of lightning pains.

SUMMARY

A review of the literature indicated that resistant tabetic symptoms such as lightning pains, gastric crises, ataxia and bladder dysfunction can be relieved in only about 50 per cent of patients by means of very vigorous chemotherapeutic procedures.

Likewise a review of so-called infectious fever therapy methods, particularly malarial fever therapy, does not show relief of intractable symptoms in over 50 per cent of tabetic patients. The mortality rate of malarial therapy ranges from 10 to 20 per cent.

A combination of artificial fever therapy by means of the Kettering hypertherm and chemotherapy has uniformly relieved intractable lightning pains and gastric crises in eleven patients. These results were obtained after other active therapeutic measures had failed. Other resistant tabetic symptoms, such as ataxia, cord bladders, paresthesias and head pains, were likewise improved in the majority of fourteen cases. Four of our patients were in the so-called burnt out stages.

I believe that this method of treating tabes dorsalis is the best method yet devised.

ABSTRACT OF DISCUSSION

DR HENRY W. VOLTMAN, Rochester, Minn. The lightning pains and crises of tabes have been particularly obstinate in their refusal to respond to treatment, and any method of therapy that has offered such uniformly successful results deserves consideration. When malarial therapy was introduced some fifteen years ago, hopes were raised even though improvement of these particular symptoms occurred in only about 50 per cent of cases. But the length of time that malaria as a therapeutic agent has been in use must also be stressed for in the years that followed it was found that even 50 per cent was too high a figure. It has also been learned that by paying attention to certain features in its use the mortality rate could be reduced considerably. Now it stands at about 0.4 per cent which is the figure found by O'Leary in the treatment of his last 800 cases. This has been achieved by paying attention to certain features. In the first place patients who are over 60 years of age, those who have a cord bladder with an associated pyleticus, those who have predominantly vascular disorders and those who have progressive optic atrophy do not tolerate malaria well. Furthermore the complications that arise in the course of malarial therapy must be taken in hand promptly. This can be done best by the administration of dextrose and saline solution intravenously. The appearance of jaundice should not be taken too lightly. Marked dehydration and in s

of salt call for replacement. There is a danger point to which Dr O'Leary has called attention. If, in the course of the malarial paroxysms the blood urea rises and the blood pressure drops, and if this course cannot be checked by the immediate administration of dextrose and saline solution the point is soon reached at which the rise in blood urea and the fall in systolic blood pressure crosses. This point is an indication for terminating the malaria. The Kettering hyperthermia in experienced hands, such as those of Dr Bennett, has advantages. The degree of hyperthermia can be controlled, making this safer in patients who are debilitated. Furthermore, if the future course of the cases Dr Bennett has reported indicates a repetition of fever therapy, it can be done with the hyperthermia, whereas this cannot very well be done by trying to reinoculate the patient with malaria. Dr Bennett's efforts deserve our warm commendation. He has again raised our hopes that something may be done for these people and we shall await his further reports with interest.

DR A. E. BENNETT, Omaha. In answer to the question about vasomotor collapse this complication has been observed in about 15 per cent of the cases. It has not been more frequent in the tabetic than in the meningovascular group. Strict attention is paid to this sign and the treatment is stopped when the patient shows such phenomenon. I didn't want to leave the impression that we think these results will hold up. As Dr Woltman has pointed out, we were encouraged over malaria therapy but have become more and more discouraged. I have no doubt that there will be relapses in this group from time to time. I simply offer this as a preliminary study and hope to follow with a larger series over a long period.

A NEW PROCEDURE FOR THE CONTROL OF BENZENE EXPOSURE

H. H. SCHRENK, PH.D.

Chemist in Charge, Toxicological and Biochemical Laboratory, Health Laboratory Section, U. S. Bureau of Mines, Pittsburgh Experiment Station

W. P. YANT, B.S.

Supervising Chemist, Health Laboratory Section and Supervising Engineer, U. S. Bureau of Mines, Pittsburgh Experiment Station

PITTSBURGH

AND

R. R. SAYERS, M.D.

Surgeon, U. S. Public Health Service

WASHINGTON, D. C.

Serious or measurable damage from exposure to benzene or any gas or vapor, obviously, can be prevented if the concentration of the contaminant and duration of exposure are so controlled that the amount absorbed is insufficient to produce damage. Unfortunately the procedures and information necessary for such control are frequently inadequate or completely lacking. As knowledge and understanding of the phenomena that accompany exposure to a gas or vapor increase, the possibility of more perfect control of the industrial disease hazards also increases.

The commonly used procedures for the control of chronic benzene poisoning are examination of the blood, particularly for evidence of anemia and leukopenia, and determination of the amount of benzene in the atmosphere. The Bureau of Mines has recently developed a microcolorimetric method¹ which has many desirable features for industrial hygiene surveys. Owing to the fact that as little as 0.001 mg of benzene

can be detected, the method is also valuable for the determination of the small amounts of benzene present in tissues and fluids in chronic poisoning.

The estimation of the toxic qualities of air from the amount of benzene present and correlation with experience and toxicologic information and data are not only useful from the point of view of control of exposure but are frequently necessary as a confirmation of a clinical diagnosis of poisoning. Chemical determinations of the atmospheric contamination are especially valuable when the persons are exposed to a rather constant concentration of benzene. However, usually the exposure is intermittent to a wide variation of concentrations, both daily and seasonal. These variations make it difficult, if not often practically impossible, to estimate the overall exposure.

In any case it is desirable to examine the exposed persons for manifestations of poisoning. The action of benzene on the hematopoietic system is well known. The occurrence of anemia, leukopenia and other changes in cell counts, such as a relative increase in the percentage of lymphocytes and decrease in polymorphonuclear leukocytes and a decrease in the number of platelets, is also considered in the diagnosis of benzene poisoning. Although none of these criteria or manifestations are specific, they accompany benzene poisoning, and the use of periodic examinations of the blood of persons exposed and observing for trends in the series of results obtained is an established procedure for the detection of benzene poisoning. Owing to the normal variations in hemoglobin content and number of blood cells and the inherent errors in the usual clinical methods of determining these constituents, a single blood examination is never satisfactory. Also, under no conditions do the usual blood examinations reveal either conditions of exposure which may produce serious poisoning if the exposure is continued or oncoming poisoning before it has progressed to the stage of determinable anemia and leukopenia. While practical application of the method has demonstrated its value, the difficulties and limitations were apparent and the importance of a better method was recognized.

In an investigation of chronic benzene poisoning conducted by the Bureau of Mines with the cooperation of the producers of benzene and The Barrett Company, observations were made during all phases of the work for striking and reliable physiologic criteria of potentially harmful exposure or indication of oncoming benzene poisoning which would be easily determined before the organism was damaged and avoid as many as possible of the disadvantages and limitations of the present procedures. The results obtained indicated that the changes in the urine sulfates might serve as an excellent measure of benzene exposure.

URINE SULFATE TEST

A correlation of the results obtained from the study of benzene poisoning revealed that exposure to benzene caused a striking, easily measurable, consistent and rapidly occurring decrease in the percentage of inorganic sulfates of the total sulfates in the urine. The decrease occurred far in advance of anemia, leukopenia or signs of harm and was quantitatively related to the benzene exposure regardless of whether the exposure was for a long period to a low concentration or for a short period to a high concentration.

Normally the percentage of inorganic sulfates of total sulfates is from 85 to 95 per cent, the remaining 5 to 15 per cent being conjugated. On exposure to

benzene there is a shift in the equilibrium of the system, inorganic \rightleftharpoons conjugated sulfates, to the right. This shift may proceed to the point of complete elimination of the inorganic sulfates.

The extent of benzene absorption is directly related to the decrease in percentage of inorganic sulfates, that is, the greater the decrease the greater the absorption. In practice the total sulfates and inorganic sulfates in the urine are determined and the percentage

hours after the specimen was voided. The tendency for the hydrolysis to occur was decreased by keeping the specimens in a refrigerator.

SCOPE OF WORK

Sulfates were determined in the urine of dogs exposed to accurately controlled concentrations of benzene vapor, which ranged from those which produced no evidence of benzene poisoning to those which produced mild to fatal poisoning. Also, approximately sixty persons engaged in work which entailed some contact with benzene were examined.

RESULTS OF LABORATORY INVESTIGATION

The total and inorganic sulfates were determined in the urine from seventy-nine dogs. As the data obtained are quite voluminous, the results of only a few pertinent experiments, which show the nature of the response, will be presented. It may be stated, however, that the changes exemplified and discussed occurred in every experiment without exception.

Chart 1 shows graphically the weight, amount of hemoglobin, number of erythrocytes and leukocytes and percentage of inorganic of total sulfates in the urine of dog 559. This dog was exposed to 800 parts per million of benzene vapor in air one hour daily for sixteen days, two hours daily for sixteen days, one hour daily for twenty-six days, no exposure for fifteen days, and finally four hours daily for 175 days. The daily duration of exposure was varied in order to study the relation between length of exposure and decrease in percentage of inorganic sulfates when the concentration of benzene in the air was kept constant.

An exposure of one hour daily to 800 parts per million caused a definite and rapid decrease in the percentage of inorganic sulfates of total sulfates in the urine from a preexposure value of above 90 per cent to from 65 to 70 per cent. An increase in the period of exposure to two hours daily caused the proportion of inorganic sulfates to decrease to a range of from

of inorganic of the total sulfates is calculated. A single specimen is satisfactory, and the volume or specific gravity of urine excreted is not necessary.

EXPERIMENTAL PROCEDURES AND APPARATUS

The benzene used in the majority of experiments was of such purity that it may safely be regarded that the effects were due to inhaling vapors of C_6H_6 . Animals were also exposed to vapors of commercial and crude benzene and the response was similar to that with pure benzene, indicating that the impurities in even crude benzene do not inhibit the sulfate response.

The test apparatus has been described² previously and has been used in many similar experiments. The concentrations could be readily controlled within the limits of ± 10 per cent of the desired concentration. A metal tray covered with fine wire screen to prevent contamination of the urine samples with food and feces was placed in the bottom of the cages. The trays were designed to drain rapidly into glass bottles. The suitability of this procedure was confirmed by normal results observed for preexposure specimens and by checking the results of pan-collected specimens with catheterized specimens.

The total and inorganic sulfates were determined by the Folin³ method. Owing to an observed tendency in some specimens for the conjugated sulfates to hydrolyze thereby increasing the percentage of inorganic sulfates when kept at room temperature for from one to several days it was considered advisable to analyze the urine samples for inorganic sulfates as soon after collection as possible, at least within twenty-four hours and preferably within twelve to sixteen

Chart 2—Dog 563 exposed eight hours daily to 100 parts per million and later to 250 parts per million of benzene vapor in air by volume.

40 to 50 per cent. On changing the period of exposure from two hours back to one hour daily, the percentage of inorganic sulfates increased to a range of the same order previously found for a one-hour exposure period. When the exposure to benzene was recessed, the sulfates rapidly returned to preexposure values. Resuming the exposure, the period was changed to four hours daily, and again there was a rapid and marked decrease in the percentage of inorganic sulfates.

Neither the blood counts, hemoglobin determinations, weight nor objective signs or symptoms showed definite or positive indications of benzene poisoning.

Chart 2 shows graphically the weight, amount of hemoglobin, number of erythrocytes and leukocytes and percentage of inorganic sulfates of total sulfates in the urine of dog 563. This dog was exposed to 100 parts per million of benzene vapor in air eight hours daily during forty-one days and then to 250 parts per million eight hours daily for a total of 124 days.

The exposure of eight hours daily to 100 parts per million of benzene vapor caused a definite and rapid decrease in percentage of inorganic sulfates, and a further decrease was produced when the concentration was increased to 250 parts per million. The blood counts, hemoglobin determinations, weight and objective signs or symptoms were not of diagnostic significance.

The fluctuation of the sulfates with the severity of the exposure and immediate return to pre-exposure values on recessing the exposure shows not only the sensitivity but also the quantitative relationship between the severity of exposure and decrease in the percentage of inorganic sulfates of total sulfates in the urine. The rapid return to normal indicates that the sulfate change is a chemical measure of exposure and not a measure of damage.

From one to two exposures to as little as 100 parts per million eight hours daily usually produced a definite decrease. The maximum decrease, for a particular exposure, occurred after from five to six exposures. The rate and magnitude of change increased rapidly with increase in concentration above 100 parts per million. With exposures that produced benzene poisoning the decrease occurred days, weeks and even months in advance of any manifestations of anemia or leukopenia or changes in weight. The interval between the decrease in organic sulfates and the blood manifestations of poisoning depended on the exposure and was longer with decreasing severity of exposure.

PLANT INVESTIGATIONS

The laboratory studies indicated the possible use of the results of urine sulfate determinations for the control of benzene exposure. A study was made, therefore, of persons exposed to benzene in industry.

The study was made at five plants where persons were engaged in making and using benzene containing dopes and coatings for artificial leather and oil cloth, benzene containing rubber cement in the manufacture of shoes and rubber goods, and in the production of benzene. In some instances the benzene vapor was accompanied by other vapors such as ethyl alcohol, ethyl acetate, butanol and gasoline. From chemical considerations it is not apparent that the exposure to these compounds, other than benzene, or their products of metabolism, would produce a significant change in the urine sulfates. A total of sixty plant employees (fifty-nine male and one female) who had contact with benzene even though remote for some individuals and thirty-three (male) control persons who had no benzene contact were studied. The control group consisted of approximately 25 per cent shop workers, 25 per cent inside laborers and 50 per cent laboratory workers. The inorganic and total sulfates in the urine, and the hemoglobin, number of red and white blood cells and platelets in the blood were determined. The concentration of benzene in the air was determined at various locations in the plants.

Table 1 shows the percentage of inorganic sulfates of total sulfates in the urine of controls and plant employees. The percentage of inorganic sulfates of total sulfates in the control group ranged from 81 to 100, with 81.8 per cent of the values being 85 or above. Only 36.7 per cent of the plant employees fell within the same range as the controls, 23.3 per cent being in the range of 70 to 80, 20 per cent from 60 to 69, and 20 per cent below 59, the lowest value being 24. These results show definitely that the percentage of inorganic of total sulfates in the urine of the exposed group is generally lower than in the unexposed group. Even though no cases of benzene poisoning were considered to exist among these persons at the time of this study, the results in table 1 indicate benzene absorption in 63.3 per cent of the persons and a significant absorption in at least 20 per cent.

Data were obtained also for hemoglobin, erythrocytes, leukocytes and platelets in the blood of these persons. Some of the values were in the range that might be considered as indicative of a tendency toward a beginning anemia or leukopenia. However, from two to three times the number of persons showed the sulfate response as showed any kind of blood manifestations of response to benzene exposure. Briefly,

TABLE 1—Percentage of Inorganic Sulfates of Total Sulfates in the Urine of Controls and Plant Employees

| Inorganic Sulfates Percentage of Total Sulfates | Percentage of Total Persons Examined | |

* Number of persons in group
† Lowest value found

the data obtained showed the sulfate response to be much more sensitive, consistent and reliable than the response of the hemoglobin, erythrocytes, leukocytes and platelets.

The change in blood cell counts and amount of hemoglobin are due to a response of the hematopoietic system, whereas the sulfate response appears to be a chemical reaction and a measure of the exposure. It is possible that some of the persons exposed to benzene who had a low percentage of inorganic sulfates in the urine and gave no evidence of anemia or leukopenia would eventually show such tendencies if the same exposure was continued. On the other hand, evidence of leukopenia and anemia may be present without a decrease in inorganic sulfates if the exposure which produced the hematopoietic response had ceased and time enough for recovery of the hematopoietic system had not elapsed.

Table 2 shows the relationship between the concentration of benzene in the air, the response of the urine sulfates and the blood manifestations of benzene exposure. In considering the results it must be borne in mind that the concentrations found represent the atmosphere at the particular point and time the sample was taken. Although the samples were taken in breathing zones, where the maximum exposure of workmen would be expected, the values obtained cannot be considered as closely representative of the all day exposure or the everyday composition of the atmosphere, even at the point sampled. There are many obvious factors

which alter the concentration of a contaminating vapor in the air actually breathed. The determinations made, however, quantitatively confirm the presence of benzene and give a general measure of the amount to which the workmen were exposed during a part, at least, of their day's work at the time the investigation was made.

A total of fifteen determinations of benzene in the air were made in the plant study. In table 2 these results are presented in four range groupings for convenience in making a correlation with the percentage of inorganic sulfates in the urine, and hemoglobin, erythrocytes, leukocytes and platelets in the blood of the plant employees.

The average for the urine sulfates in group 1 is in the range of normal values. This is in keeping with the low concentration of benzene from 13 to 23 parts per million found in the air and the observed cleanliness of the working places of these particular employees. The average results for blood examinations are within a normal range.

The average values of the urine sulfates for groups 2 and 3 are similar and show a moderate though distinct decrease, although the values for the air concentrations vary considerably. The reason for the apparent irregu-

TABLE 2—Relationship Between Benzene Concentration in Air, Response of Urine Sulfates and Blood Manifestations of Plant Employees

| Group No. | Number of Men | Concentration of Benzene P P M | Average Value for | | | | Platelets Thou sands |
|-----------|---------------|--------------------------------|--|----------------------------|--------------------------|------------------------------|----------------------|
| | | | Percent age of Inorganic of Total Sulfates | Hemo globin per Cent Sahli | Red Blood Cells Millions | White Blood Cells Thou sands | |
| 1 | 14 | 13-23 | 83 | 91 | 4.9 | 7.5 | 153 |
| 2 | 6 | 19-60 | 70 | 90 | 4.6 | 6.5 | 141 |
| 3 | 22 | 123-132 | 72 | 85 | 4.5 | 6.4 | 131 |
| 4 | 13 | 158-372 | 55 | 85 | 4.0 | 6.8 | 124 |

larity in the relation of sulfate response to benzene exposure is that the employees of group 2 made frequent trips through other parts of the plant where the benzene concentration was greater, whereas group 3 was not exposed continually to the concentration shown. The average results for blood examinations of this group were within a normal range.

Group 4, which represents those employees exposed to the highest concentration of benzene found by analysis and also by an observation of the working conditions, showed a marked decrease in inorganic sulfates. The average results for blood examinations of this group with the possible exception of the number of platelets were within the normal range.

In general, table 2 indicates that the decrease in urine sulfates is a much more sensitive and distinct indication of response to benzene exposure than the blood manifestations.

SUMMARY

The commonly used procedures for controlling benzene poisoning consist of determining the amount of benzene vapor in the air and examining the persons exposed for manifestations of anemia and leukopenia. These methods either alone or in combination are not entirely satisfactory. Owing to daily and seasonal variations in the concentration in the air it is practically impossible to determine the overall or average concentration to which workmen are exposed. Blood manifestations of diagnostic significance do not occur until after sufficient damage has been produced to affect adversely the functioning of the hematopoietic system.

The percentage of inorganic of total sulfates in the urine has been found to decrease on exposure to benzene. The decrease is quantitatively related to the severity of the exposure, that is, increase in severity of exposure, whether due to continued exposure to a low concentration or a short exposure to a high concentration, causes a more marked decrease in the percentage of inorganic of total sulfates. The response is consistent, reliable and occurs in advance of anemia, leukopenia or other manifestations of benzene poisoning. Only a single "grab" specimen of urine is necessary, and the method of analysis is simple and easily carried out.

ABSTRACT OF DISCUSSION

DR HENRY FIELD SMYTH, Philadelphia. I was privileged to see some of this work a year ago and felt that it was a very interesting, suggestive contribution and that it would be of great help in industry in evaluating the exposure of workers. The experiments checking the work with employees in the plant follow out the suggestions of animal experimental work and if it is assumed that approximately 100 parts per million is the safe limit for workers, as suggested by the National Safety Council Survey, this is a method which apparently will indicate when a man is exposed to overdose. In the paper on animal experimentation, reference was made to using carbon tetrachloride, which was not mentioned here. Carbon tetrachloride will have the opposite effect. It produces liver damage and interferes with conjugation of sulfates. Research workers found when they combined carbon tetrachloride with benzene that they blanked this shift in the ratio by the carbon tetrachloride interfering with conjugation. After this fact was brought to my attention, my associates and I tried to see if we could make any use of that method of determination of exposure in our carbon tetrachloride work, but I came to the conclusion that it was much less valuable there, partly because normal inorganic sulfates run too high. We did make a special trip to a nearby plant and got about a dozen samples and examined those according to this technic, and we did find up to 100 per cent in some of them, but the ratios found did not agree with known exposures. In our animal experimental work we ran these tests, and in groups exposed to 200 parts per million of carbon tetrachloride found a definite difference between the normal and the exposed animal. The normal small animal we found had not as high a proportion of inorganic sulfates as is normal to man, so we could show a difference there which, when the groups were considered, had some significance. When the individual animals were considered, however, the difference was not great enough to say that this animal was exposed to carbon tetrachloride and that one was not.

DR PAUL A DAVIS, Akron, Ohio. I should like to ask the authors whether they have been able to hook up the symptom complex with the concentration of sulfates in any way at all so that it would be possible to determine the point of toxicity. I want to know whether through their determinations of inorganic sulfates they are able to arrive at anything definite where one might expect these symptoms to develop.

DR H H SCHRENK, Pittsburgh. We have not attempted to establish a concentration of inorganic sulfates in the urine which may be considered the threshold at which symptoms will eventually appear. The purpose of the test is to prevent benzene poisoning. If the results of urine analyses indicate a definite absorption of benzene, consideration should be given to the improvement of the exposure conditions.

DR R R SAYERS, Washington, D C. It is hoped that a number of those who deal with benzene and industrial solvents will try the method. It would seem that it might be useful as a tool and for directing attention to where the hazard may occur, where the hazard exists and thus one can prevent damage before it occurs. I believe from the data shown that even though the inorganic sulfates fall to almost zero, or even to zero, it doesn't necessarily mean that there has been any damage produced provided the condition is corrected.

PHYSIOLOGIC RELATIONSHIPS BETWEEN
INTRATHORACIC, INTRASPINAL
AND ARTERIAL PRESSURESW F HAMILTON, PH D
R A WOODBURY, MD
AND
H T HARPER JR, MD
AUGUSTA, GA

In 1934 one of us with Brewer and Brotman¹ described an optical manometer which offered certain advantages over those in use at that time. The customary² rubber membrane carrying a flat mirror was discarded for a thin metal disk and a 0.5 diopter planoconvex lens silvered on the plane side. The new mirror design made it possible to lengthen the optical lever and to get photographic tracings of unusual clarity, and this with the simplest of optical arrangements. The disk (coin silver 0.0015 inch thick) increased the volume elasticity coefficient of the system to such a degree that it was possible to increase its effective mass 500 fold or more.

In accordance with the mathematical principles laid down by Otto Frank,³ we were free from the limitations imposed by a small effective mass and could construct a manometer that was much more convenient, flexible and adaptable than its predecessors.

Figure 1 is a diagram of it in its present form. Attention might be called to the convenience of using a long lead tube (up to 4 feet) armed with an ordinary hypodermic needle as a cannula and of thrusting this needle into an arterial or other cavity to record accurately the pressure pulsations within it. This is done with no surgical procedures.

By the simultaneous use of two or more manometers we have recorded the quantitative comparison of the pressures in the several parts of the cardiovascular system and the relationship between pressures in the cerebrospinal or thoracic cavities and those in the arterial or venous system.

One practical question of wide interest is: How accurate is the ordinary auscultatory method of blood pressure measurement? It must be emphasized that its criteria have been established by inference and that direct checks have not been obtained until recently. Such checks have been made by Wolf and von Bondsdorff⁴ and are now being continued in the Georgia school. Our results indicate that the indirect method agrees reasonably well with the direct method. The indirect method seems to be 3 or 4 mm low in evaluating the brachial systolic and about 9 mm high for diastolic (using the fading of the fourth phase). This summarizes the results of some thirty comparisons on random clinic patients. There is evidence already that in different clinical conditions the comparisons will check up in a different manner, but we are not yet in a position to go into greater detail.

We now wish to bring up the question of the relationship of pressures in one artery to those in another

artery. If the pressure pulse inscribes its contour by means of a quantitative manometer, we have the maximal (systolic) pressure recorded as the heart empties blood into the arterial tree and a minimal (diastolic) pressure recorded just before the next heart beat. Now, if we take simultaneous recordings of the pressure within several arteries and replot them to the same pressure scale, it will be seen that, though there are no very significant differences in diastolic pressure, the systolic pressures progressively increase as we go from the axillary, near the heart, to the femoral and then on down to the foot (dorsalis pedis) (fig 2). The femoral exceeds the axillary by 20 mm and the dorsalis pedis exceeds the axillary pressure by 55 mm. Differences similar to these seem to be usual. In all our patients diastolic pressure is nearly equal in all the arteries, but what systolic pressure is depends on the artery.

The physical factors behind this increase in systolic pressure as the pulse wave approaches the periphery are not fully analyzed. They seem to operate in the lower limbs and abdominal aorta to a greater extent

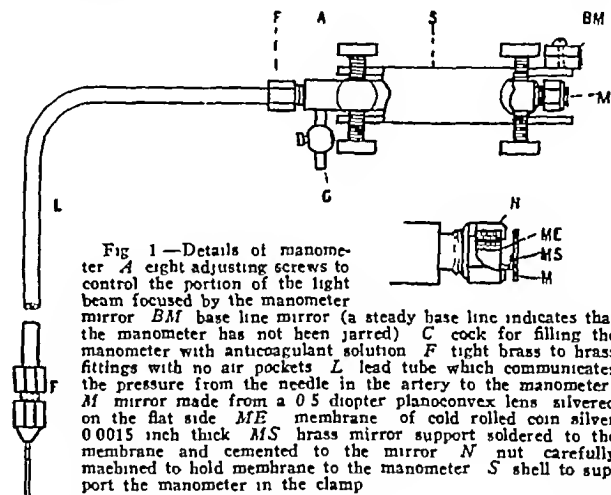

Fig. 1—Details of manometer. *A* eight adjusting screws to control the portion of the light beam focused by the manometer mirror. *BM* base line mirror (a steady base line indicates that the manometer has not been jarred). *C* cock for filling the manometer with anticoagulant solution. *F* tight brass to brass fittings with no air pockets. *L* lead tube which communicates the pressure from the needle in the artery to the manometer. *M* mirror made from a 0.5 diopter planoconvex lens silvered on the flat side. *ME* membrane of cold rolled coin silver 0.0015 inch thick. *MS* brass mirror support soldered to the membrane and cemented to the mirror. *N* nut carefully machined to hold membrane to the manometer. *S* shell to support the manometer in the clamp.

than in the arteries of the arm. It may be possible as a result of careful study to separate the factors that have to do with the volume elasticity characteristic of the arterial tree⁵ with the inertia and momentum of the surging blood column⁶ and with the velocity potentials of Bernoulli. Rapid pressure pulsations are of importance because, when a patient coughs and the pressure is maintained above systolic for a fair part of a second, the difference in pressure between the two arteries disappears. It reappears as the pulsations begin again.

The effect of coughing brings up the next topic, namely, the relation of intrathoracic pressure to arterial pressure and, later, to the pressure in the cerebrospinal fluid. For the intrathoracic pressure studies, the subjects were tuberculous patients with artificial pneumothorax. Straining and coughing seem to give the same blood pressure changes in these patients as in the normal, though in the normal simultaneous records of intrathoracic pressure were not made.

The pneumothorax and brachial artery were entered with 22 gage needles attached to similar manometers. The upper tracing in figure 3 is of the brachial pressure and next below is a tracing of the intrathoracic pressure. When the intrathoracic pressure went up, the

subject strained as in a bowel movement, increasing the intrathoracic pressure to a value of 50 mm of mercury. The effort was maintained ten seconds and then suddenly released.

At first glance it seems that the blood pressure is passively supported by the intrathoracic pressure. The two pressures seem to go up together and come down together. We notice, however, that there are distinct changes in the pulse contour and in the heart rate.

T. L. 22836

Fig 2—Human arterial pressure curves from axillary (A) femoral (F) and dorsalis pedis (DP) arteries. The original record (upper right) has been replotted so that the pressures in the arteries are shown on the same scale. Axillary \approx 165 mm of mercury femoral = 200 mm. and dorsalis pedis = 235 mm systolic.

The pulse contours fall into two different types, which we shall call for convenience full pulses and empty pulses. There are of course intergradations. The full pulse is seen during the recovery from the strain at the end of the tracing. It is marked by a wide pulse pressure and a relatively high diastolic pressure. The empty pulse, on the other hand, is produced by the

L. B. 24616

Fig 3—Straining. From above downward are shown brachial arterial pressure, intrathoracic pressure and base line with signal. The net blood pressure is the arterial pressure minus the intrathoracic pressure. The three lines indicate systolic (S), diastolic (D) and dicrotic (N) pressures. The intrathoracic pressure curve has been inverted and plotted to the blood pressure scale (shown in millimeters of mercury at the left). The lower base line is divided into seconds.

discharge of an inadequately filled heart. It resembles that seen in experimental shock in dogs. The pulse pressure is narrow and the diastolic pressure is often as low as the systolic.

If one is to understand the causes of the changes in pulse contour and rate it is convenient to subtract the intrathoracic pressure from the arterial pressure and replot the effective pressure of the blood within the thorax.

This gives the cardiovascular component of the blood pressure as distinguished from the intrathoracic. It is an index as to how the heart itself is working and as to the available pressure to feed the coronaries. We shall refer to this as the net blood pressure. In this chart the lowest curve is the intrathoracic pressure plotted to the blood pressure scale and inverted. The net blood pressures (systolic [S], diastolic [D] and dicrotic notch [N]) are plotted to the same scale, seen on the left.

We shall divide the response to the strain into four phases.

1 The blood pressure rises and the pulse becomes slightly fuller. This rise produces no change in heart rate, though it acts of course on the carotid sinus. The net blood pressure does not rise and soon begins to fall.

2 In the second phase the pulmonary reservoir becomes depleted. Cardiac filling is inadequate and the pulsations become of the empty type. They are mere ripples on the arterial tree and leave the artery as empty at the beginning of diastole as at the end. As this phase continues, some other factor enters (peripheral vasoconstriction perhaps) and the mean (net) blood pressure begins to rise again.

3 In the third phase the strain is let off and the general blood pressure falls precipitously to the level

Fig 4—Effect of coughing. Curves arranged as in figure 3. Note that the intrathoracic arteries (coronary and the like) are protected from the elevated arterial pressure produced by the cough.

of the net (intrathoracic) blood pressure. The intrathoracic pressure has ceased to support the blood pressure.

4 Immediately the heart becomes better filled. The pulse pressure widens, systolic and diastolic pressures increase, and the dicrotic notch is higher on the diastolic contour. These changes reach their maximum in four seconds. Blood that has been dammed back in the extrathoracic venous reservoirs makes its way clear through the lesser circulation and produces a maximum effect on the arterial blood pressure in this short time.

The mean blood pressure does not rise in this fourth phase any higher and sometimes not as high as in the first phase, but the heart slows markedly. The depressor receptors of the carotid sinus⁷ are stimulated alone in the first phase but in the fourth the receptors in the aorta are also stimulated because the net (aortic) blood pressure rises while in the first phase the rise is confined to the extrathoracic arteries.

When a patient coughs there is a bizarre increase in the blood pressure curve. Figure 4 is a simple example. The cardiac pulsations are overshadowed by other waves, which often last throughout diastole and may raise the arterial pressure to twice the systolic value. These have been recorded from normal human subjects.

and in patients with pneumothorax it is possible to record the simultaneous changes in intrathoracic pressure

From simultaneous arterial and intrathoracic pressure curves the net blood pressure has been plotted in the same manner as before. In figure 4 the intrathoracic pressure changes are not very sudden and the cardiac pulsations in the net blood pressure are not greatly altered

Fig 5—Effect of coughing. From above downward are shown the brachial arterial pressure cerebrospinal fluid pressure base line the net cerebrospinal arterial pressure base line showing seconds and the inverted cerebrospinal fluid pressure curve plotted to the blood pressure scale shown on the left. Note arterial pulsations in the cerebrospinal fluid pressure curve during recovery from a strain.

When the cough is more sudden, the net blood pressure may recede to zero, i.e., there is momentarily no effective coronary pressure. In a severe paroxysm of coughing the systemic blood pressure shows very large and erratic increases, but the net blood pressure still retains the marks of the cardiac rhythm in spite of increases and decreases of thoracic origin. The coughing leaves the heart inadequately filled and the pulses relatively empty.

These very large increases in arterial pressure on coughing and straining put a degree of stress on the arterial tree and give rise no doubt to interstitial hemorrhages. Because of their serious consequences, such hemorrhages have received particular attention when they occur within the craniospinal canal.

Evidence to be presented in detail elsewhere shows conclusively that quick changes in intrathoracic pressure are transmitted directly and immediately to the craniospinal canal. These pressure changes are not propagated to the cerebrospinal fluid by the internal jugular vein, because they are slower and less extensive in that vessel than in the canal itself. They are not propagated over the arterial tree. An ordinary systolic rise in arterial pressure causes a rise of intraspinal pressure of only 1 or 2 mm of mercury. A similar rise in arterial pressure caused by a cough is accompanied by a rise in intraspinal pressure as great as or even a bit greater than the arterial rise itself (fig 6).

This evidence leads us to regard the craniospinal cavity as a sort of functional extension of the thoracic cavity and to think of the cerebrospinal arteries as protected from the sudden stress that results from straining and coughing in the same fashion that the intrathoracic arteries are protected.

Thus in figure 5 the rises in systemic blood pressure that occur as a result of coughing do not appear in the net intraspinal pressure. They are canceled by similar rises in cerebrospinal fluid pressure. In figure 6 the same is seen to be true during a strain. The net

intracranial blood pressure fails to rise as does the systemic blood pressure, but just as in the thorax it does rise after the strain is over. Moreover, the intracranial pressure pulsations are much more extensive after a strain than before or during the effort. It is at this time that the strain puts its greatest stress on the cerebral arteries.

The net intraspinal blood pressure, which is analogous to the net intrathoracic blood pressure, is of course the force that tends to burst the arteries and to produce apoplexy. One cannot fail to be struck by the admirable way in which the vital arteries within the craniospinal canal, within the thorax, and to a great extent within the abdomen are protected against these sudden and enormous physiologic increases in pressure.

Admitting the existence of these pressure relationships and their usefulness, what is there to say about the mechanism that results in the prompt and opportune rise in intracranial pressure? As we have seen, the pressure cannot be propagated from the thoracic to the craniospinal canal by the arteries or the internal jugular veins. How then do these sudden and large pressure changes occur in such a rigid bony box as the craniospinal canal?

The following hypothesis is at present the most attractive. We would suggest that the pressures which arise during coughing and straining in the thoracic and abdominal cavity are transmitted through soft tissues between these cavities and the spinal column to the spinal foramina. Because of the rigidity⁸ of the cerebrospinal canal and because of the temporarily increased vascular pressure, no very large tissue or fluid volume would need to be squeezed into the spinal canal in order to raise the pressure even to the extent it does during the cough. The material entering the spinal canal under this stress may be (1) cerebrospinal fluid from under the evaginations of the dura around the spinal nerves, (2) the spinal nerves themselves and loose areolar tissue surrounding them, and (3) venous blood in the paravertebral plexuses, and in the larger veins at the back of the thorax and abdomen in close communication with these veins.

The pressure increases that are, according to our notion, produced in the spinal canal must naturally be propagated up through the foramen magnum and into

Fig 6—Straining curves arranged as in figure 5. Note that the cerebrospinal arteries are protected from the elevated arterial pressure produced by the coughs.

the cranial cavity. Even though the volume movement up through the base of the skull is small, the pressure thrust is considerable. A similar and opposite thrust occurs as the intraspinal pressure goes down. The fact that these stresses are localized at the base of the brain may have some bearing on the frequency of hemorrhage in this region.

SUMMARY

1. The manometer here described can optically record quick pressure changes in the human body with a high degree of accuracy.

2 Experiments show that the true systolic and diastolic blood pressures are not very different from those recorded by the auscultatory method

3 Simultaneous recordings of arterial pressure in the axillary, femoral and dorsalis pedis arteries show that the latter two exceed the former by such figures as 20 and 55 mm of mercury respectively, systolic. Diastolic pressures are nearly equal

4 Simultaneous records of arterial and intrathoracic pressure show that the intrathoracic and probably the intra-abdominal arteries are protected from the large pressure fluctuations which coughing and straining produce in the systemic blood pressure

5 Similar changes occur in the spinal pressure during straining and coughing which protect the arterial tree within the craniospinal canal from these unusual stresses. Thus a simultaneous sudden rise of arterial and spinal pressure of 100 mm of mercury resulting from severe coughing leaves the net intraspinal arterial pressure unaffected

ABSTRACT OF DISCUSSION

DR RALPH H MAJOR, Kansas City, Mo. My observations, using the apparatus supplied me by Drs Hamilton and Woodbury, have been limited to experimental animals. As clinicians we can derive satisfaction from the observation that, checked by this accurate method, our ordinary methods of taking the blood pressure of patients are quite satisfactory. This method, however, in the study of problems connected with hypertension or with disturbances of circulation, does many things that the ordinary blood pressure equipment does not. One of the most interesting features of this apparatus is the fact that it enables one to get away from the inertia of mercury. I have been astounded to see the terrific elevations of blood pressure that follow the administration of pressor substances. These elevations of blood pressure cannot be taken with a mercury manometer, since the mercury has too much inertia to follow these quick changes in pressure. For instance, I have seen systolic pressures as high as 400 mm and diastolic pressures as high as 300. It is possible to demonstrate these very rapid changes only with such an apparatus. Since seeing some of these tracings in animals and a few that Dr Woodbury has shown me on patients, I feel a little more respect for such substances as epinephrine. The authors didn't have time to bring that out in their paper, but I am sure we would be interested to have him refer to that in his closing discussion. Another interesting feature of his paper has been the demonstration of the effect of coughing on the coronary circulation. I wonder just what happens to the coronary circulation of a patient who has pneumonia and coughs continually. It makes one wonder if perhaps we shouldn't take the heart a little more into account than we seem to be doing at the present time. This new method of estimating the blood pressure opens new fields for exploration. Much of the work that has been done on blood pressure in anesthetized animals must be revised in the light of methods that estimate the pressure of patients and animals without the administration of drugs.

DR R A WOODBURY, Augusta, Ga. We have modified our cannulas so that we have a special type which enabled us to follow blood pressure changes in small animals such as rats and mice. This will allow experimental workers to follow blood pressure changes in these animals, obtaining systolic and diastolic pressures, for a long period without sacrificing the animal. This technic will be described elsewhere. We hope to continue this work in the field of drug studies both in animals and in man. Preliminary work with epinephrine on human beings has shown some very striking blood pressure changes. The first patient receiving epinephrine had asthma. He was given a fairly large injection 0.45 cc. of 1:1000 not any larger than is given every day in outpatient clinics or in the emergency room. The pressure of this individual became elevated to such a height that we were not able to get the record. I know it went over 380 because we could have followed any changes to 380 mm of mercury. We have studied

the effect of smaller doses since that time and observed very definite periods of arrhythmia as a result of epinephrine. We hope to continue our studies on other cardiovascular drugs in animals and human beings. Another field which we expect to study is the strains that occur during parturition. We have noticed that the longer the strain the bigger the rise following the release of the strain. We expect to find some interesting changes following parturition pain and the strain that accompanies it.

UNTREATED SYPHILIS IN THE MALE NEGRO

A COMPARATIVE STUDY OF TREATED AND UNTREATED CASES

WASHINGTON, D. C.

A determination of the effectiveness of treatment in preventing the transmission of syphilis is one of the basic problems in the control of this disease. Second in importance to it is the effect which treatment has in preventing late and crippling manifestations. The administration of adequate treatment in early syphilis is recognized as the most important factor in the prevention both of communicable relapse and of the early complications so detrimental to the health of the individual patient. As the result of surveys of a few years ago in southern rural areas it was learned that a considerable portion of the infected Negro population remained untreated during the entire course of syphilis. Such individuals seemed to offer an unusual opportunity to study the untreated syphilitic patient from the beginning of the disease to the death of the infected person. An opportunity was also offered to compare this process, uninfluenced by modern treatment, with the results attained when treatment has been applied.

The material included in this study consists of 399 syphilitic Negro males who had never received treatment, 201 presumably nonsyphilitic Negro males, and approximately 275 male Negroes who had been given treatment during the first two years of the syphilitic process. All these individuals were more than 25 years of age. The percentage of persons in each age group is comparable. The method of case finding and study has as far as possible been comparable and nonselective. The patients with untreated syphilis and presumably nonsyphilitic individuals were chosen primarily by the use of the Kolmer complement fixation and the Kahn standard flocculation tests for syphilis and subsequently by the presence or absence in the history of the early manifestations of syphilis. A total of 1,782 male Negroes aged 25 years or more were serologically examined in a rural county. Of these, 472 gave at least two positive serologic tests for syphilis. From this group the 399 patients with untreated syphilis were taken for this study. Only individuals giving a history of infec-

Read before the Section on Dermatology and Syphilology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

The authors are indebted for cooperation and assistance in conducting this study to the personnel of the John A. Andrew Memorial Hospital, Tuskegee Institute, Ala.; the U. S. Veterans Administration, Fort Tuskegee, Ala.; the Macon County Health Department, Tuskegee, Ala.; and the State Department of Health, Montgomery, Ala.

tion who submitted voluntarily to examination were included among the 399 patients. Of the total 1,782 Negro males, 1,258 were found to be serologically negative for syphilis. Persons in age groups comparable to the untreated syphilis cases were taken from these 1,258 serologically negative individuals, provided a subsequent serologic study gave no evidence of syphilis and a history of infection was absent.

The examinations included a careful history, a detailed physical examination, routine teleroentgenologic study of the heart and great vessels in the anteroposterior position, roentgenologic study of the osseous system if indicated, and a spinal fluid examination in 271 of the 399 patients with untreated syphilis. The routine examinations were performed by physicians trained in clinical syphilology. The assistance of specialists was utilized when manifestations were such as to require unusual examinations.

The case records of patients with syphilis who received varying amounts of treatment during the first two years of their disease were available for this study. These case records were from the syphilis clinics of five universities which have undertaken retrospective clinical studies under the guidance of the Public Health Service. Roentgenologic study of the chest was not routine in this group, although such studies were made when indicated. The spinal fluid was examined in a larger percentage of the untreated syphilitic patients than in the treated syphilitic group.

The present study presents the physical and mental condition of a cross-section of the untreated seropositive syphilitic male Negro population. The problem offered by those individuals who had been infected with syphilis but who had spontaneously become serologically negative will not be discussed here. No data are available that indicate the frequency with which negative serologic tests spontaneously develop in the Negro with latent or late syphilis. Reports from the current medical literature indicate that approximately 75 per cent of patients with active late syphilis have positive serologic tests, regardless of whether or not they received previous treatment. In the recent studies¹ of the Committee on Evaluation of Serodiagnostic Tests for Syphilis, 3,961 specimens from 307 patients with latent and late syphilis were examined by thirteen participating serologists. Most of these patients had received varying amounts of treatment, a few were untreated. Among the 3,961 specimens examined, 2,976, or 75.1 per cent, were positive. The present study, therefore, represents the condition of at least three fourths of the untreated syphilitic Negro population.

MORBIDITY IN UNTREATED SYPHILIS

A comparison of the physical and mental condition of the untreated syphilitic patients with the apparently nonsyphilitic Negroes in the general population permits an estimate of the effect of syphilis in the production of morbid processes involving the various systems of the body. Only 16 per cent of the 399 untreated syphilis patients gave no evidence of morbidity, as compared to 61 per cent of the 201 presumably nonsyphilitic Negroes. The effect of syphilis in producing disability in the early years of adult life is to be noted by comparing the cases with no demonstrable morbidity under 40 years of age. This comparison shows that only

one fourth of the Negroes with untreated syphilis had no manifestations of disease, whereas three fourths of the uninfected population were free.

With an increase in age there is, as one would expect, an increase in the frequency of manifestations of cardiovascular involvement due not only to syphilis but also to arteriosclerosis and hypertension. Modern diagnostic methods have not as yet progressed to such an extent that most signs and symptoms of cardiovascular disease are recognized as pathognomonic on an etiologic basis. This is especially true for the earlier manifestations of disease involving this system of the body. The manifestations of aortitis here recognized were those which have been generally accepted as diagnostic for several decades, as well as those which have more recently been emphasized by Carter and Baker² and Moore, Dangle and Reisinger.³ Roentgenologic manifestations of increased aortic width and the presence of two of the remaining six signs of these investigators were considered to be diagnostic evidence of

aortitis. The roentgenologic readings were based on the interpretation of observations as outlined by Vaquez and Bordet.⁴

Study of the untreated syphilitic and presumably nonsyphilitic individuals under the age of 40 years indicates that syphilis in this period tends greatly to increase the frequency of manifestations of cardiovascular disease. It is to be noted that of 174 syphilitic individuals under 40 years, 25.3 per cent had definite manifestations of cardiovascular disease, as compared with 5.7 per cent of eighty-seven individuals in the same age group who were nonsyphilitic. A difference may still be noted in individuals over the age of 40, although this difference is not so pronounced. Of 225 untreated syphilitic patients over 40 years of age, 63.1 per cent had definite manifestations of cardiovascular disease as compared with 37.7 per cent among 114 nonsyphilitic individuals.

Perhaps the most interesting group of patients in the study, because of their potential amenability to treatment, are those who have presumptive evidence of uncomplicated aortitis. Because of the strictness of present-day criteria, these cases could not be definitely

diagnosed. Of the untreated syphilitic patients, 23.6 per cent had presumptive evidence of uncomplicated aortitis, while only 5 per cent of the nonsyphilitic patients presented such evidence. In the early years of adult life, especially among untreated syphilitic patients, it is more common to have either roentgenologic or clinical evidence of increased aortic width alone than it is to have a combination of the two. In later years, however, the corroborative evidence more frequently permits a definite diagnosis of uncomplicated aortitis. This fact is so striking that presumptive evidence of aortitis should be regarded as of great importance and patients giving such evidence should be subjected to long periods of observation and treatment. The exact interpretation of these manifestations awaits more definite proof, which it is hoped may be accumulated by following the untreated syphilitic individuals over a period of years, a number being ultimately brought to autopsy. Such an attempt is now being made with the assistance of a philanthropic organization. The purpose is to confirm

the presumptive manifestations of cardiovascular disease if possible and to corroborate the accuracy of clinical observations in general.

The incidence and character of syphilis of the central nervous system in the Negro has been a controversial issue for many years. Generally speaking, one group of observers believes that dementia paralytica and tabes dorsalis are not particularly common in the Negro race. A second group is of the opinion that parenchymatous neurosyphilis occurs almost as frequently as in the white race. In this study 26.1 per cent of 399 untreated syphilitic Negro males had either clinical or serologic evidence of central nervous system involvement. Only 2.5 per cent of the 201 nonsyphilitic Negroes, on the other hand, had any disease of the central nervous system.

Analyzing our data further, we find that of the 399 untreated syphilitic patients 7.8 per cent had definite clinical evidence of central nervous system syphilis, while in an additional 18.3 per cent the diagnosis of central nervous system involvement was based on serologic evidence only. The untreated syphilitic patients included 3 per cent of a relatively benign parenchymatous type and 4.8 per cent with all other forms of central nervous system involvement. In the latter group the most serious type was the vascular form.

With regard to the benign parenchymatous type, such patients did not appear to run the usual classic course of dementia paralytica or tabes dorsalis. The manifesta-

tations that were common included positive reactions in the spinal fluid, and changes in the pupillary reactions and tendon reflexes. No typical cases of dementia paralytica or tabes dorsalis were noted but one case of simple dementia was found. In order to be certain that there was no selection of patients through loss to institutions for the insane, it was learned that not a single male Negro over 25 years of age was confined with syphilis of the central nervous system in the Searcy Hospital at Mount Vernon, Ala., where the Negro insane in this state are hospitalized.

In the group of 399 untreated patients with syphilis, forty-six (11.5 per cent) gave evidence of late involvement of the bones, joints and skin. Of these, thirty-six patients (9 per cent) showed periostitis, osteitis or Charcot's joints. Two patients, or less than 1 per cent, presented late syphilis of the skin, and eight (2 per cent) had both a late skin and a bone or joint involvement.

EFFECT OF TREATMENT

All syphilologists recognize the great importance of the provision of treatment during the first two years of the syphilitic process, and all are likewise of the opinion that treatment during this period should be adequate. An accurate evaluation of the modern treatment of syphilis is, however, made difficult by many factors. First of all, adequate treatment has not been freely available to most indigent citizens for a period longer than a decade. Furthermore, not until about twenty years ago was the administration of the arsphenamines started in this country on a large scale. In comparing the results obtained by modern treatment with those in untreated patients, it is important that both groups be observed for a definite period. An observation period of at least twenty or more years is necessary to give a true picture of the value of therapy. The incompleteness of records of patients treated in the past often does not permit such a comparison. Final evaluation of treatment must await the accumulation of well kept records of patients treated and observed over a sufficiently long period.

In connection with the administration of adequate treatment, the tendency of all patients, whether white or colored, is to become dilatory in returning to the attending physician during the observation period. If the individual remains symptom free and the physician has assured him that adequate treatment has been administered, repeated return for observation soon becomes irksome. The consequent lapse tends to distort the results obtained with adequate treatment, since patients who suffer no relapse fail to return, while those presenting intractable manifestations are prone to return for long continued treatment.

In the following discussion more than twenty doses of an arsphenamine with an accompanying heavy metal preparation are arbitrarily classified as minimum adequate treatment. Less than this amount has been called inadequate. Among sixty-eight individuals who were adequately treated during the first two years of their infection, not a single one returned with any of the manifestations of late syphilis. The fact that none of these patients returned up to the fifteenth year of observation with a late syphilitic manifestation indicates that effective treatment has definite preventive value against the crippling manifestations of late syphilis. The degree of protection is even more manifest if a comparison is made with the patients with untreated syphilis during comparable periods.

Table 2 permits a comparison, at intervals of three, six and nine years after the syphilitic infection began, between untreated patients and those receiving inadequate treatment. Among eighty-six inadequately treated male Negroes whose infection was of three years' duration, as compared with twenty-six untreated patients in the same chronological period, 12 per cent of the former had evidence of a cardiovascular involvement as compared to 77 per cent of the latter. Syphilis of the central nervous system was present in 93 per cent of the inadequately treated patients in this period, as compared with 30.8 per cent of the untreated individuals. The preponderance of the late manifestations of syphilis in the untreated patients as compared with the inadequately treated continues throughout the years of observation. Nine years after the onset of the syphilitic infection the inadequately treated patients had 69 per cent cardiovascular involvement and 13.8 per cent central nervous system involvement, as contrasted with 41.9 per cent and 29.0 per cent respectively among the untreated syphilitic Negro males.

CONCLUSIONS

1 The clinical and laboratory observations in 399 adult male Negroes with untreated syphilis and 201 presumably nonsyphilitic adult male Negroes in comparable age groups permit a comparative determination of the extent of morbidity due to untreated late syphilis.

2 The results indicate that the cardiovascular system is the most commonly involved in the late syphilitic process and the aorta is the most commonly involved structure in so-called latent syphilis in the adult male Negro.

3 Morbidity in the male Negroes with untreated syphilis far exceeds that in a comparable presumably nonsyphilitic group.

4 Adequate antisyphilitic treatment prevented all forms of clinical relapse during the first fifteen years of the infection, whereas only one fourth of the Negroes with untreated syphilis were normal.

5 Cardiovascular and central nervous system involvements were from two to three times as common in the untreated syphilis group as in a comparable group receiving even inadequate treatment.

ABSTRACT OF DISCUSSION

DR. CHARLES C. DENNIE, Kansas City, Mo. Dr. Vonderlehr and his co-authors have some ideas concerning the involvement of the central nervous system in Negroes. It is a great deal higher than we have been led to expect. Central nervous system syphilis in the colored races is somewhat lower than it is in the white. It is believed by many authorities that the presence of malaria in countries inhabited by the colored or the Indian race is responsible for the comparative absence of central nervous system involvement. The second school states that it is the comparative resistance of the central nervous system to syphilis in the colored races that is responsible for the smaller number of involvements. It is known from the work of Peterson that the Negro who migrates to the North develops more tabes dorsalis and dementia paralytica, likewise that in the northern countries with a large Negro population, such as in Kansas City, with 50,000 Negroes, that there is a comparatively small number with involvement of the central nervous system. In Kansas City at present and for many years there has been practically no malaria, so that malaria as an influence cannot be considered. From observation in other places it must be concluded that the color of the skin has some effect on the smaller number of central nervous system involvements. I have observed in Brazil, during a short stay, not only the incidence of syphilis but also the incidence of malaria. The hydro-electric plant built for the city of São Paulo, a city

of some 1,200,000, one of the largest municipal hydro-electric plants in the world, was constructed in the midst of a malaria infested district. In an examination of 25,000 applicants for jobs on the construction only 8,000 were free from malaria. This figure may be taken as a fair indication that 75 per cent of the population are suffering from either chronic or acute malaria. It is stated by the Brazilian authorities that the incidence of syphilis in the city of Rio de Janeiro is about 35 per cent. The incidence of dementia paralytica and tabes dorsalis, however, is much lower than it is among the more northern countries. It must therefore be assumed that the comparative freedom of the colored races from central nervous system syphilis is due to two causes: first, a racial influence that modifies the action of the organism of syphilis on the central nervous system, a lessened threshold value for symptoms even where they do have the asymptomatic symptoms of the central nervous system, and, second, the presence of malaria in a comparatively large percentage of the population.

DR. HARRY M. ROBINSON, Baltimore. After all these years, since 1905, when progress in the knowledge of syphilis really started or was awakened, it is surprising to find how ignorant the average medical man is of the treatment of syphilis. Of course in every large clinic these figures which Dr. Vonderlehr and his co-workers have shown are known, they vary somewhat in the various clinics, we see probably a few more patients with dementia paralytica, still more optic atrophies in the Negroes than others have reported, but nevertheless the important thing is that we have noted the fact that syphilis is not merely a chancre and consequent secondary skin lesions, but a ravaging disease which destroys the organs of the body. It is a pity that not more emphasis is laid on this fact, because in visiting smaller towns I am struck with the fact that much ignorance is displayed on syphilotherapy. Many students write us that the competition in their communities is too great for them to insist on our outlined course of treatment. The average physician in their community advises a course of seven to ten injections of arsphenamine or a bismuth compound as a complete treatment for syphilis.

DR. ARTHUR SCHOCH, Dallas, Texas. It is gratifying to get some accurate figures with regard to the incidence of syphilis. It seems that most of these studies must originate in governmental departments rather than private clinics. In Dallas we have recently done a study in an attempt to find out the incidence of syphilis in the outpatient clinic at Baylor Hospital. We purposely selected the year of 1934 to go through 3,300 records, because during that year our clientele at the clinic was recruited from a slightly higher social level than usual. The general incidence of syphilis in the outpatient department was 17 per cent. The incidence in white patients was 9 per cent, in colored patients it was 31 per cent. We then subdivided these patients, trying to ascertain the approximate incidence of syphilis coming from the various departments, such as medicine, surgery, obstetrics and gynecology. Taking the department of medicine as a base line, we found that the incidence of syphilis coming in through the medical department in white patients was 12 per cent. We then compared the incidence of syphilis coming from the various specialties. Obstetrics gave the lowest percentage, 2. Interestingly enough, such narrow specialties as ophthalmology and otolaryngology showed an incidence of 8 per cent, as compared to 12 from internal medicine, only 1 per cent less of the general incidence of syphilis of all white patients who came to the outpatient department for various reasons.

DR. JAMES K. HOWLES, New Orleans. Several years ago a neurologist presented at a meeting in Kansas City a case of dementia paralytica in a Negro. I was surprised to find at New Orleans a clinic that was treating an enormous group of patients. We treat an average of 1,300 to 1,800 syphilitic patients a week in the antisyphilitic clinics of Charity Hospital, which gives an idea of how many colored patients we see. We are trying to systematize the treatment and the investigation so that our records will mean something. But the point I wish to stress is that central nervous system syphilis isn't rare in the colored, in fact, it is almost as prevalent in our clinics as in the white, but of course our white cases are far in the minority as compared with the colored cases. We have investigated why there

are so many complaints of a cardiovascular nature in the colored people. In analyzing some 1,400 cases with an internist, I find that the symptoms they give relative to cardiovascular syphilis vary so much that they have to be greatly discounted in the cases of the colored females. In analyzing some 1,400 cases and examining them thoroughly, with the aid of electrocardiograms and roentgenograms of the chest, we found that most of the complaints in the colored female are groundless, whereas the complaints in the colored males are not stressed enough. I bring up these two points to show that there is a lot to be learned in the classification of syphilis in the colored and I believe that with such studies as the author has presented, in the course of a few years we shall be able to get somewhere.

DR. R. A. VONDERLEHR, Washington, D. C. I wish to assure Dr. Howles that we had considerable difficulty in taking the histories of syphilitic Negro males. The average Negro is a most congenial person and he has a tendency to agree with almost anything that one wishes him to agree with. We spent an hour or more getting each one of these histories. Dr. Dennie brought up the question of the influence of malaria on the incidence of central nervous system syphilis. We inquired from each of these Negroes whether he had ever had malaria or typhoid. I believe around 25 or 30 per cent of the Negroes reported that they had had one or the other of these diseases. We have available this analysis, which we expect to report ultimately in a more detailed paper on syphilis of the central nervous system in the Negro. The incidence of syphilis was not more frequent in the group which had never been infected with either malaria or typhoid. In other words, there was no difference in the two groups after breaking down our figures.

Clinical Notes, Suggestions and New Instruments

A SUBTROCHANTERIC OSTEOTOMY

F. HAROLD DOWNING, M.D. AND ROBERT H. MORRIS, M.D.
BOSTON

Subtrochanteric osteotomy of the femur for flexion adduction deformity of an ankylosed hip is a common and widely used corrective operative procedure. It has been our experience that most methods commonly in use do not allow accurate control of the distal fragment. It is not uncommon for this fragment to slip following osteotomy during correction of the deformity and override the proximal fragment. This has also been known to occur during closure of the wound and even several days after operation even though a hip spica was used for fixation. Usually the affected leg is already too short and the additional shortening is anything but desirous. It is likewise not unusual to find on removal of the spica that there has been a gradual loss of the correction of abduction. When the extremity is placed in the abducted position it causes considerable tension on the adductors which have become shortened from contracture by adaptation to the adducted position. This constant tension has a tendency to rotate the pelvis within the spica and thus minimize the correction. It is our intention to report a method which, although both simple and easy, completely overcomes these difficulties.

Due credit must be given to Brackett for introducing the curved subtrochanteric osteotomy, which was designed to allow the distal fragment to rotate on the concave proximal end thus allowing the distal fragment to be rotated without danger of slipping. However, in performing a curved osteotomy with an osteotome alone there is always danger of a breaking off of the important medial tip of the proximal fragment which is extremely necessary. It is this portion which prevents the distal fragment from dislocating medially. By outlining the desired curve first with a series of one-fourth inch drill holes one fourth inch apart (A in illustration) and using an osteotome only for cutting the bone left between (B) it is possible to control accurately the exact place, curve and angle of the

osteotomy. When the osteotomy has been completed, one finds that the opposing surfaces resemble those of opposing gears and it is very easy to rotate the distal fragment into any desired position. One is sure of accurate fixation, for the "cogs" fit into each other in the new position (C) and prevent any immediate or future danger of slipping, thus avoiding overriding or rotation of the pelvis with the resultant loss of correction. We have found it best to make the proximal frag-

A the desired curve is first outlined with a series of one fourth inch drill holes one fourth inch apart. B the intervening bone is cut with a half inch osteotome. C the distal fragment is rotated on the concave proximal fragment till the desired correction is obtained.

ment as short as safely possible and plan to have the curve extend from the region of the lesser trochanter upward and outward to just below the greater trochanter. The operation is then performed chiefly in very vascular cancellous bone and union is very rapid. A hip spica is used for fixation, the plaster extending from the toes of the operated leg to the middle of the thorax.

REPORT OF CASE

A woman, aged 46, admitted to Brooks Hospital Oct 7, 1935, with a diagnosis of an old healed tuberculosis of the left hip, left knee and spine, had $4\frac{1}{2}$ inches shortening of the left leg. The left hip was ankylosed in 40 degrees flexion and 40 degrees adduction.

October 9, under general anesthesia, a 6 inch longitudinal incision was made on the anterior lateral aspect of the left thigh just below the region of the greater trochanter. The soft tissues were divided in the same plane and the region of the femur exposed extending from the lesser trochanter to just below the greater trochanter. A series of one-fourth inch drill holes one-fourth inch apart was then made in a curve from the lesser trochanter upward and outward to just below the greater trochanter, the drill being directed posteriorly and slightly upward. The intervening bone was cut with a half inch osteotome, the instrument being directed in the same plane. On completion of the osteotomy, the leg was rotated into 15 degrees abduction and full extension. The wound was then closed in layers and a single hip spica applied. The post-operative convalescence was uneventful. The spica was removed in ten weeks but the patient was allowed to remain in bed for another four weeks before being allowed up on crutches. By the end of six months union was firm and full weight bearing was painless. The correction had not changed.

COMMENT

We have reported and described an operation for flexion adduction deformity of an ankylosed hip which we believe to be much better than those in common use for the following reasons:

- 1 It is simple and easy to perform.
- 2 The location, extent and angle of the bone fracture can be accurately controlled.
- 3 There is no danger of unforeseen fracture.
- 4 One has perfect control of both fragments during the entire operative procedure.
- 5 Fixation is easy with no immediate or future danger of slipping.
- 6 The callus is abundant and union is rapid.
- 7 There is little or no operative shock and the postoperative convalescence should be uneventful.

253 Newbury Street

The use of drill holes for outlining the location for an osteotomy was first learned indirectly by one of the authors through Dr. J. K. Adams but we have recently discovered that a procedure closely resembling the one described has been used at the Massachusetts General Hospital. No published account could be found.

Special Articles

THE CHOICE OF OINTMENT VEHICLES IN DERMATOLOGY

BERNARD FANTUS, M.D.

Professor of Therapeutics University of Illinois College of Medicine
CHICAGO

This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned out developed through the cooperation of the U S Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—ED

Unless it be in the domain of surgery, there is no other department of therapeutics in which physical influences determine to so great an extent the success or failure of therapy as in dermatology, and it certainly behooves the physician to take special interest in dermatology, for nowhere else in medicine do errors in treatment manifest themselves so promptly as they do in skin disease.

Chief among the physical influences that govern the effect of remedies is solubility. In dermatology it determines whether the application will stick or not and, as with the postage stamp, the first requisite of a skin remedy is that it must stick. If it does not, the surface cannot be properly covered with the application and whatever remedy it is intended to carry cannot influence the affected area as it should. What is still worse, when a dense fatty ointment is applied to a surface from which it is lifted off by accumulating discharge, the latter serves as a culture medium for the ever present micro-organisms, and these, by the poisons they produce, may cause irritation, sometimes erroneously ascribed to "idiosyncrasy" of the patient.

The first division, therefore, of the ointment vehicles must be made on the basis of affinity into "lipotropic" and "hydrotropic" applications. The former, having fat affinity, include ointments and cerates, cling to the fatty surface of the skin, and are indicated as long as the surface is relatively intact and fatty. When the epithelial layer of the skin is lost, as in case of an ulcer or excoriation, or the surface is moist, as in "weeping eczema," a hydrotropic preparation—i. e., one with water affinity—to which the term "paste"¹ might be applied, is likely to be much superior to a lipotropic preparation.

Probably the next most important basis for division in case of the ointment vehicles rests on differences in melting point, and the dividing line must be the temperature of the skin of the covered parts of the body, say, 98 F. Fatty applications of a melting point above that of the surface of the skin are known as cerates, because the increase in melting point was formerly secured largely by the presence of wax (cera). Fatty applications with a melting point at or below the temperature of the skin are known as ointments.

CERATES

Of the three U S P cerates, two are suitable as vehicles for dermatologic applications, the third one, the Cantharides Cerate, being the basis for blistering plasters employed in counterirritation.

From the Laboratory of Pharmacology and Therapeutics University of Illinois College of Medicine

¹ While the use of the word "paste" in this sense is favored by leading pharmacists the National Formulary Committee has not yet had the courage to change the well established name for Lassar's paste (paste of zinc oxide) to a more distinctive ointment title.

Cerate (Ceratum), or Simple Cerate, a mixture of thirty parts of wax and seventy parts of benzoated lard, forms when spread on gauze or linen a bland protective dressing for surfaces the natural protective layer of which, the epidermis, is deficient or defective and that are secreting but little fluid. It has the advantage over a preparation which melts at the temperature of the skin that it does not liquefy and run through a dressing as an ointment would but stays in the place where it is wanted and keeps the dressings from sticking to the raw surface. Medicating such preparations with other than volatile material is largely delusional, because "substances do not act unless they are in solution," and a fatty material that does not melt effectually seals nonvolatile ingredients against access of solvent.

That volatile ingredients become active in spite of such a handicap is illustrated by the Rosin Cerate (Ceratum Resinae), which is somewhat irritative owing to a trace of turpentine that cannot be separated from the Rosin, of which the cerate contains 35 per cent. Rosin, be it remembered, is the residue left after distilling off the volatile oil (Oil of Turpentine) from the concrete oleoresin Turpentine. Such an irritative dressing is superior to a bland protectant when stimulation to healing is desired. As the cell proliferation induced by such irritants is nonspecific, it will favor the growth of connective tissue quite as much—indeed relatively more—than that of epithelium and thus lead to the development of exuberant granulations. Hence, when there is a tendency to the formation of proud flesh, nonspecific irritants of this kind are contraindicated.

OINTMENTS

Because ointments liquefy at the body temperature and are of a fatty nature, they are the most important vehicles for carrying medication to the skin.

Ointment (unguentum), also known as Simple Ointment, is petrolatum with 5 per cent each of Wool Fat and of White Wax, which additions permit the incorporation of a certain small amount of fluid in the otherwise "hydrophobe" petrolatum. This is a salve vehicle employed in most of the official medicated ointments and it is advisable for physicians to use it in their prescriptions instead of Benzoated Lard, which is objectionable on account of its tendency to rancidity.

PRESCRIPTION 1—Ointment Containing Ten per Cent of Pine Tar

| | |
|---------------|---------------|
| R Pine Tar | 30 Gm |
| Ointment | 300 Gm |
| Mix and label | Apply locally |

If, for instance, a physician desires to prescribe an ointment containing 10 per cent of Pine Tar, he might write prescription 1.

The official Pine Tar Ointment contains 50 per cent of Pine Tar, which proportion may be too irritative for a certain case of subacute dermatitis, while in another case the 10 per cent Tar Ointment might be too weak and the 50 per cent Tar Ointment might be required.

Differences in consistency are perhaps the chief reason for choice among the various official ointments that might be considered salve vehicles. These range from the fluffy softness of Rose Water Ointment and the emollescence of the Zinc Oxide Ointment to the relative denseness and great covering qualities of the Paste of Zinc Oxide of the National Formulary. To

bring out clearly the differences in the use of these, a detour into fundamental principles may be desirable.

As a general proposition, ointments are contraindicated in acute inflammatory conditions of the skin, because of their "heating" quality. This is due largely to the fact that, by inhibiting the evaporation of sweat, they check the cooling influence this would exert and, in consequence, induce hyperemia of the skin.

CREAM OINTMENTS

An exception to this general proposition regarding ointments occurs with the cream ointments, in which the "heating" qualities of fat are antagonized by the water

PRESCRIPTION 2—Ointment for Pruritus

| | | |
|-------------------------------------|---------------------|----------|
| R | Menthol | 0.03 Gm |
| | Phenol | 0.60 Gm |
| | Rose Water Ointment | 30.00 Gm |
| Mix and label Apply to itching skin | | |

incorporated in them by means of emulsification. The cooling sensation produced by the evaporation of the water, when such ointments are applied to the skin, has given them the name of "cold cream." These emulsions also have the advantage of making the application more suitable to relatively moist surfaces, as emulsified fat clings to them fairly well.

As the classic type of such cream ointments may be mentioned the official Rose Water Ointment (*Unguentum Aquae Rosae*), a preparation invented by Galen nearly 1,800 years ago. In its various modifications cold cream has become progressively more popular. Galen's method consisted of soaking rose buds in olive oil and, after straining, mixing it with melted wax, which—acting as an emulsifying agent—permitted the incorporating of water, a little at a time, until a white creamy ointment was secured. Today in the official formula the same principle is employed, but a better product is secured by modification of the ingredients. Diluted Rose Water is emulsified in Expressed Oil of Almond (56 per cent) by means of Spermaceti (12.5 per cent) and White Wax (12 per cent). Sodium Borate (5 per cent) is added, as it improves the keeping qualities and favors emulsification, and a tiny quantity (0.02 per cent) of oil of rose is added to strengthen the flavor.

Because of its cooling quality, rose water ointment is a good vehicle for ointments against itching. Thus, against pruritus with intact epidermis, prescription 2 may be prescribed.

PRESCRIPTION 3—Decongestive Application for Weeping Eczema

| | | |
|--|---------------------------------------|-----------|
| R | Solution of epinephrine hydrochloride | 15.00 cc. |
| | Wool Fat | 5.00 Gm |
| | White Petrolatum | 10.00 Gm. |
| Mix and label Apply to the affected skin | | |

Greatly overshadowing its therapeutic use in importance is the employment of cold cream as a cosmetic, and for its different uses, various modifications of its character are required, from "vanishing creams" to "emollient creams."

Vanishing cream is simply an emulsion of stearic acid in water containing soap. Very little of the stearic acid is required to produce the ointment-like consistency.

When "vanishing cream" is applied to the skin, it does not really vanish. After evaporation of the water

there is left a thin, practically invisible, nongreasy layer, which forms a good basis for the application of powder. When used for this purpose it is often spoken of as "foundation cream."

"Cleansing cream," used as a detergent, is nothing more or less than an extremely superfatted soap, possessing maximal cleansing with minimal irritative action. When all that can be said in favor of "vanishing cream" and "cleansing cream," it must be pointed out that they cannot be used for the purpose of soothing, for which the official Rose Water Ointment is largely employed, as they do have an irritative quality, even though a very slight one.

The beauty culturist sharply contrasts these from "emollient creams," which are soothing and chiefly intended for night use. These serve largely as restoratives, to replace the natural lubricant of the skin, which is removed excessively by the so frequent washing of the skin demanded by modern feminine hygiene.

The emollient creams fittingly contain Wool Fat, which in its chemical composition resembles the sebum closely and hence might be considered the ideal restorative for the sacrificed fat of the skin. Wool Fat is, in addition to this, an excellent emulsifying agent for water in fat or even in Petrolatum, which is—as is well known—not a true fat. When one melts together White Petrolatum and Wool Fat (say, equal parts or even three parts of the former and one part of the latter) one can incorporate in this mixture as much as an equal weight and even twice its weight of aqueous

PRESCRIPTION 4—Rose Water Ointment

| | | |
|---|---------------------|---------|
| R | Rose Water Ointment | 60.0 Gm |
| Label Use as a soothing application to the skin | | |

fluid. Thus, in "weeping eczema" the decongestive application given in prescription 3 may be useful, not only to decongest but also to relieve itching of the excoriated, therefore water absorbent, surface.

From what has been said, it is evident that it is inadmissible to employ glycerin instead of the rose water as has been proposed for cold cream, because of better keeping qualities, for glycerin is nonvolatile and, being hygroscopic, irritative by withdrawing water from the skin. It is also obvious that it is poor policy for the physician to tell his patient to get "any good cold cream" and apply it to the affected part, because there is no telling what kind of cold cream the patient would get. It is better to write a prescription for the official preparation.

ZINC OINTMENTS

The official Ointment of Zinc Oxide (*Unguentum Zinci Oxidi*) contains 20 per cent of the Zinc Oxide, which, one may visualize, might increase the soothing effect of the Simple Ointment, which is the vehicle, by the zinc combining with irritative acids produced at the seat of the disease. It is also possible that the opacity of this salve is of value by shutting out the irritative rays of sunshine.

After an ointment has been applied, something generally needs to be done to keep it in place. For soft ointments, some nonabsorbent material, such as oiled silk, rubber tissue or paraffin paper, or a wire gauze screen dressing is required, otherwise the coverings get more ointment than the skin.

With as dense a salve as the "Paste" of Zinc Oxide (Lassar's "Paste"), which contains 25 per cent each of

Zinc Oxide and Starch in White Petrolatum, keeping it in place is less of a problem. It is so firm that, after its application, liberal dusting with Talcum forms a crust which keeps it in place. On exposed surfaces, a "face powder" of suitable skin color may be used, which has the advantage of making the application less conspicuous.

The Paste of Zinc Oxide (Pasta Zinc Oxidi), formerly official in the National Formulary under this title, contained 2 per cent of salicylic acid. Owing to the fact that this addition occasionally produced irritation, it has been deleted from the formula now official under this name, and the preparation made according to the old formula must now be prescribed for under the title Paste of Zinc Oxide with Salicylic Acid (Pasta Zinc Oxidi cum Acido Salicylico). It is very probable that in most instances of subacute dermatitis, for which Lassar's Paste is a very useful and popular application, the presence of the salicylic acid is of value. It would be more rational, however, were the physician to prescribe the exact amount of salicylic acid he desires, which in one case of trichophytosis (ringworm, athlete's foot) may need as low as 1 per cent and in another as high as 10 per cent. The latter strength is needed when curative exfoliation is required, but it is certainly much too great in cases with an acute inflammatory reaction.

It is, indeed, a good general principle that the medicating ingredient should be added by the physician to meet the indications present rather than that a medicated ointment be ordered, for no set formula can take care of the needs of all the various conditions met in practice. By habitually prescribing fixed formulas, the physician never acquires the "sense of proportion" that should enable him to fit the remedy properly to the case. A 10 per cent salicylic acid ointment is simply ordered by writing prescription 5.

PRESCRIPTION 5—Ten per Cent Salicylic Acid Ointment

| | |
|---------------------|-------------------------|
| R Salicylic Acid | 30 cc. |
| Paste of Zinc Oxide | 300 Gm |
| Mix and label | Apply to affected parts |

As to their influence on absorption through the skin, of which so much was made in the past, recent studies point to the conclusion that the vehicle has little if any influence on absorption, excepting a retarding action. A volatile drug, such as methyl salicylate, which is absorbable through the skin will be absorbed regardless of the vehicle. Even with such volatile material, the quantity absorbed, when applied in ointment form to

PRESCRIPTION 6—One per Cent Gentian Violet Paste

| | |
|---|--|
| R Methylrosanilin | 0.5 Gm |
| Tragacanth | 3.5 Gm |
| Physiologic Solution of Sodium Chloride | 50.0 cc. |
| Mix and label | A thick layer of this paste on four or five thicknesses of gauze to be applied as a dressing |

the human skin, is so small as to indicate that the fatty ointment vehicles exert a retarding influence on absorption of drugs through the skin. Nonvolatile substances are practically not absorbed through the skin, unless they are lipotropic, as is, for example, cantharidin.

PASTES

For moist raw surfaces a paste, e. g., one containing tragacanth, is much more likely to meet the indications than an ointment. Thus, for the treatment of an acute burn of limited extent, after a preliminary application

of a compress of 25 per cent magnesium sulfate solution, a 1 per cent gentian violet paste may be ordered, as in prescription 6.

The Tannic Acid dressing, life saving in extensive burns, is not desirable for those of limited extent, as the surface layer of cells must be sacrificed to its coagulant action.

These examples might suffice to demonstrate that it does make a difference what ointment vehicle is chosen. It may make the difference between success and failure.

**EFFICIENT LABORATORY SERVICE IN
THE SYPHILIS CONTROL PROGRAM**

ARTHUR J. CASSELMAN, M.D.

CAMDEN, N. J.

NOTE—The article by Dr. Arthur J. Casselman and the articles by Drs. John H. Stokes and N. A. Nelson, which follow conclude the symposium on the control of syphilis, the other articles in which by Drs. R. A. Vonderlehr, Dudley C. Smith and Joseph Earle Moore, appeared last week.—Ed

The laboratory service to be discussed here is limited to the examination for spirochetes and serologic tests for syphilis. These are the important public health laboratory tests used during the most infectious period. It is beyond the scope of this discussion to include urinary tests for nephritis from treatment by heavy metals, icterus index tests for the extent of arsenical hepatitis, or even colloidal gold tests of the cerebrospinal fluid. Although attempts are being made to break down barriers and make no distinctions between public health laboratory work and the innumerable other laboratory tests useful in the private practice of medicine, present budgets will not permit the addition of these other examinations without the sacrifice of more necessary tests and without lowered efficiency.

The first opportunity to diagnose syphilis and the best time to treat it is in the primary stage. About ten or more days after the infecting contact, when the sore first appears, at which time the diagnosis usually can be made with certainty only with the microscope, is the first and best chance to eliminate a source of infection by means of accurate diagnosis and treatment.

The ordinary darkfield examination should supplant substitute diagnostic methods of less reliability, such as India ink preparations, or staining by silver or by various aniline dyes. The darkfield examination for syphilis is a technical procedure which needs to be done under the best of conditions to make it reliable. The sore should have been free of any local antiseptic for at least twenty-four hours before the examination is made, and no general antisyphilitic treatment should have been given. It is surprising however, to find that in many cases the most radical forms of local treatment have had no influence in causing a disappearance of the spirochetes of syphilis. On the other hand, it is usually a waste of time to look for spirochetes twenty-four hours after an adequate dose of neoarsphenamine.

The two most important factors in the examination are the use of a satisfactory instrument and a careful operator. At one time the market was flooded with poor instruments, such as supstage condensers in the form of a heavy glass slide, and certain types of

substage condensers which when adjusted were continually sliding or dropping out of correct optical position. Then there was the type with a tiny substage electric bulb as an entirely inadequate source of light. The operators were even worse than the instruments. Many persons were using the darkfield apparatus, usually an inadequate type of this instrument, without any training and without a careful study of the manufacturer's directions. The operator rarely was paid for his services, which also were more urgently required elsewhere. For these and other reasons, chiefly economic, syphilis being most common to the "on relief" type of person, the darkfield examination is a much neglected diagnostic procedure. Yet, under proper conditions, the darkfield examination can be made the most accurate and efficient diagnostic procedure for the control of syphilis.

This examination can be made more readily available to persons in distant rural communities by adopting the procedure of having specimens sent by mail to the central state laboratory, as long advocated by Harrison in England. This method of having darkfield examinations done by mail must always be considered as an inefficient substitute for the examination of the patient by an expert diagnostician. There are many errors that are likely to creep into the diagnosis made by mail. In the first place, the serum from the sore is removed by a novice, any one doing sufficient work to be an expert would have his own darkfield apparatus. The novice is not so likely to know or observe the rule that no antiseptic should be used on the sore for at least twenty-four hours before the examination, that no internal antisyphilitic drug, particularly intravenous arsphenamine, should be used before the darkfield examination, that the sore should be cleansed mechanically and the serum should be removed preferably from the edge of the ulcer, and that the specimen should contain not too many red blood cells. It is possible also for the expert to remove fluid from enlarged glands when the examination of the sore is unsatisfactory.

This examination is best made by an expert physician who can afford to give it the necessary time and care. These conditions can best be met by the physician who maintains a private diagnostic laboratory, or by the diagnostician in a syphilis clinic which is not too much rushed with other work. If there is a sufficient volume of work, the microscope should be set up permanently for darkfield examinations only. The cardioid type of substage condenser produces the best illumination, much better than the paraboloid type. Certain arc lamps produce the best light but usually they are expensive and troublesome. There are many satisfactory filament lamps producing as much light as the 100-watt projection bulb. Most of these, to be satisfactory, need a condensing lens. A satisfactory cheap type is the variety that utilizes a flask of water as a condensing lens between the light bulb and the microscope. It is a good plan to have the microscope and light source screwed fast in proper relation to each other on a board, to avoid time-consuming adjustments. Keeping a microscope out of general use in this manner may seem extravagant, but if the apparatus is not always ready for use the examinations are liable to be neglected. This is a costly examination and it will not be done properly unless the costs are met either by private or by public funds.

To encourage the use of this test all possible facilities must be encouraged. When it is apparently impossible for the patient to get transportation to an

expert, the examination of specimens sent by mail in capillary tubes to the state laboratory, as has been done notably in New York State, is the best substitute. I believe it would be better for the patient to travel a hundred miles or even more to get the more efficient examination, but, since few patients can be induced to travel the necessary distance in some rural communities, a substitute is necessary, such as the examination of mailed specimens.

A substitute for the darkfield examination of the primary lesion, which is widely used but is recommended only as a very poor substitute, is a sensitive flocculation or complement fixation blood test. If the serologic test used is very sensitive, many cases will be diagnosed by the third week, and most by the fourth week of the presence of the primary lesion. On account of the fact that at present patients usually delay for about two weeks before coming to a physician for an examination of a primary lesion, the substitution of a sensitive serologic test for an immediate darkfield examination results in a delay in diagnosis and the institution of treatment of only about two weeks. The public needs more education to induce them to have earlier examinations, and better darkfield facilities must be provided.

In New Jersey about ten years ago the state attempted to increase these facilities by supplying darkfield apparatus to those venereal disease clinics which were without any or had very poor equipment, and various other clinics have received similar aid in the past years. One large city laboratory, at the Newark City Hospital, without any state aid, has been providing free darkfield service to the citizens of Newark without any restrictions. This free service is much less used than would be expected in a city of 450,000 inhabitants. During 1935 only thirty-four darkfield examinations for syphilis were made in this laboratory. Some of the reasons for this lack of use are the competition of the large city clinic with its own darkfield service and the competition of many private laboratories. But this competition is an insufficient reason for the small number of examinations made in all these laboratories. The state should attempt to encourage the use of all these laboratory facilities and is doing so. The state medical society should be provided with an accurate list of all public and private facilities, and this list should be corrected annually and printed annually in the state medical journal and be distributed by other suitable means to all the physicians of the state. Technical information should always be available on application to the state venereal disease control officer. Proper standards should be maintained through the cooperation of the state department of health and the state medical society.

The serologic tests become tests of more importance about five weeks after the appearance of the primary lesion. Although the Wassermann test is still perhaps the most widely used test, the various flocculation tests cannot be ignored by any private or public health laboratory.

The Wassermann test has continually been modified in various details ever since it was devised. This test is somewhat complicated and therefore there are many steps, each of which through intensive research has many suggested improvements. The infinite number of possible combinations of these various improvements has brought out numerous named and unnamed modifications. The important improvements are few but so outstanding that about them there is almost unanimous opinion. It is generally believed that there should

be a fairly close titration of the hemolytic system, so that weak fixation is not obscured by the presence of an oversupply of complement, that better fixation is obtained by prolonged fixation at low temperatures (from 2 to 8 C) for from four to eighteen hours than by the old method of fixation at higher temperatures for shorter periods, and that a strong purified antigen such as the alcoholic extract of powdered heart muscle which has been thoroughly extracted with ether and fortified by the addition of cholesterol is preferable to a crude alcoholic extract of syphilitic liver or other whole tissue. These improvements have been devised largely to increase sensitivity. These refinements were necessary to avoid missing so many cases of syphilis, particularly those in the early primary stage and those in which much but still inadequate treatment has been given, and some cases of late syphilis. The test, however, is not qualitatively specific for syphilis, so that the more sensitive the test, the more likely it is to give some degree of reaction in various persons with a marked disturbance of metabolism, such as occurs in some pregnancies and in various febrile and other conditions. Thus, with careful technique sensitivity is largely an index of lack of specificity. For diagnostic purposes, therefore, it is necessary to relate the sensitivity to some more uniform standards than the names of various serologists.

Attempts at standardization have been made by various national and international committees and various individuals. Standardization has not been accomplished, probably because the attempt has been to standardize the constantly changing procedures rather than the results obtained. Various League of Nations conferences have established approximate comparative values to the various modifications of the Wassermann and flocculation tests, and recently a similar evaluation was sponsored by the United States Public Health Service¹ at the request of the American Society of Clinical Pathologists. These comparisons of the various modifications were made by the use of identical liquid samples of blood and spinal fluid by the participating serologists. The results showed which tests were the more sensitive in a general sense but did not establish any biologic standard as in the case of diphtheria antitoxin.

Standardization by dried syphilitic serum was suggested in 1926,² but this plan was complicated by the poor keeping qualities of serum dried by any simple method. In the meantime, the difficulty of preserving dried serum has been overcome by Flosdorf and Mudd,³ by the relatively simple method of freezing the serum and drying it in vacuo while still frozen. Such a method of standardization is being tried out in New Jersey with their cooperation in drying standardized serum. The results of this study will be published elsewhere. It is planned to supply all New Jersey laboratories, public or private, with ampules of this dried serum, so that they can check their tests from time to time. The basic standard used is a serum which is only strong enough in Wassermann-fixing substance to give practically complete fixation with a very sensitive Wassermann test. It is probable that serum in a dried state will be supplied also for checking the Kline and Kahn flocculation tests.

Wassermann tests should be done chiefly in laboratories in which the volume of tests is large, preferably not less than twenty-five per week, because of the much greater expense per test when only a few tests are made. The flocculation tests are better suited to the smaller laboratories, on account of the stability of the reagents and the rapidity with which the tests can be carried out, particularly the Kline slide test. The greater simplicity of the precipitation tests should not, however, lead to the error of having them done by untrained persons. The studies of the Committee for the Evaluation of Serodagnostic Tests for Syphilis in the United States showed that, of the tests used, the better varieties of flocculation tests apparently could replace the Wassermann tests. Most serologists seem reluctant to discard the more complicated and expensive but older and more familiar, Wassermann test.

Whether the Wassermann, Kline, Kahn or other sensitive test is used, the most important reagent in maintaining proper sensitivity is the antigen. The supplying of a reliable antigen by the state department of health to all laboratories would be the cheapest measure to bring all tests up to a satisfactory standard of sensitivity. In New Jersey, small quantities of antigen have been supplied in special cases to a few laboratories. It is hoped that budgetary limitations will not prevent the extension of this service in a systematic manner. It may be necessary, because of the expense, to limit supplies of antigen to small quantities which local laboratories could use merely for checking against their own antigens. But whatever plan develops, this cooperation should extend to all private as well as public health laboratories. If dry standardizing serum and antigens are supplied to local laboratories it may be well to ask them to cooperate and to report to the state all strongly positive serologic reactions. These reports would be used for checking against the reports of syphilis required by state law, as is done with reports from the state and certain other laboratories. Caution must be used in asking such cooperation of laboratories, as they are already overburdened with nonproductive clerical work, such as the making of too many duplicate reports.

There are some who object to state and municipal laboratories providing free diagnostic laboratory work for syphilis, on the ground that it is improper competition with privately operated laboratories. This diagnostic service was at first provided by private initiative and brought up to a high state of perfection. Theoretically it may be argued that if this diagnostic service is furnished by state or county or city laboratories its use should be restricted to the poor. Such restriction is difficult to put into practice. Usually this free competition with private laboratories takes away much of the work from the private laboratories except when it is evident that the tests are poorly done in the government laboratory. The government laboratory may be inefficient because of an attempt to run on an inadequate budget, but the budget is sometimes inadequate also in a private laboratory because of a small volume of work. "The possibility should be borne in mind that under certain circumstances local private laboratories may be subsidized to advantage for the performance of laboratory work."⁴

Syphilis is a disease of the poor, being present among the poor from two to four times as frequently as among the middle or richer classes. The poor are more commonly unwilling or unable to pay for the necessary diagnostic measures. These diagnostic measures would therefore be almost completely neglected among the largest class of syphilitic patients if they were not provided for by taxation or by private hospitals.

SUMMARY

Darkfield examinations are most efficient when the patient is sent to the laboratory of a diagnostician who has the proper equipment. If there are many localities too far distant from a darkfield expert, the state laboratory should examine specimens sent in capillary tubes.

Wassermann tests are usually best done in a laboratory doing at least twenty-five tests a week. Kline or Kahn tests may be done in a small laboratory immediately and checked by Wassermann tests in a central laboratory later.

The state laboratory should cooperate with local private and public health laboratories by supplying them with weak standardized and dried syphilitic serum, and also by supplying sensitive antigens for both Wassermann and flocculation tests.

301 North Second Street

EDUCATION OF THE PHYSICIAN AND THE MOVEMENT FOR VENEREAL DISEASE CONTROL

JOHN H. STOKES, M.D.
PHILADELPHIA

The health authority is vitally concerned with problems of education in general and with that of the physician in particular. The ideal health officer should himself be an exemplar of the educated physician—not only learned in his special field but a cultivated gentleman with a perspective on human life as well as human ills. In the ideal relationship between the health authority and the body of practitioners of medicine, he should deal with equals as cooperators rather than with pawns to be moved and governed. In such a relation the vital concern of both sides for each other's intellectual and professional equipment is evident without discussion. But there are special and cogent reasons why in the field of venereal disease control the health officer must give exceptional weight to his educational relations, contacts and obligations to physicians. At a time of planning and adjustment for health responsibility, it is particularly necessary that they be kept in the foreground.

The everyday doctor's cooperation is essential. I would emphasize to health officers from such perspective as I have on the field, first, that they cannot in a country such as ours, from the standpoint of tradition, of geography or of population distribution, dispense with the active and constant cooperation of the everyday doctor both in diagnosis and in treatment. No mechanism of state owned or subsidized clinics, no machine tactics, no pushing aside no effort to fence about and till the venereal disease field as an organizationally controlled public health problem will be wholly effective. The reasons have been discussed elsewhere and cannot

be reviewed here.¹ Few patients will travel a mile to a clinic, except under economic pressure, if they can travel a block to a fair doctor. Close the doctor's eyes, discourage his interest in diagnosis, discourage his activity in treatment, and not only does his concern for diagnosis lapse but the mere mechanics of number, distribution and accessibility of patients silently defeats an infection control program except in the most densely populated centers. Do not, therefore, as one public health enthusiast of my acquaintance did, believe that a fiat establishing of a few hundred or a few thousand clinics by executive manifesto in this country is all that is needed to stamp out syphilis and gonorrhea and their minor associates. The examples of Scandinavia and Great Britain, of which much will be heard, are special cases, comparable in a way to the metropolitan areas of our larger cities or to compact homogeneous and traditionally stable population units like the states of New York and Massachusetts. You who will travel everything from the corduroy trail and the gumbo road to the concrete streamlined boulevard highway and must meet the need of the crossroad and the slum cannot afford to neglect, even less to alienate, the everyday doctor. I proceed with my discussion in the belief that we should set out to enlist his cooperation and to equip him for the needs of the program by every educational device that can be conceived and applied.

SOME GENERAL PRINCIPLES

From general educational experience the lesson may be drawn that, the earlier educative processes are set in motion, the better the finished product and the faster it is turned out. Long range and intensive planning should begin, therefore, with the seedling doctor rather than with the aging oak. The older doctor has, to be sure, one great advantage over the embryo and the young one in the learning process—he realizes keenly what he has missed and yearns for it. In the field which the average doctor must serve in a venereal disease program, however, this is too often a tragically late and ineffective virtue. For alertness, for technical proficiency, for the energy to chase down and to put through, we should concentrate on the young. For the coordinative, the reflective and the experimental, we may then perhaps deal with the mature, but only if previously adequately grounded.

From the field of general education, too, come precious items of technic. Methods of education through eye, ear and hand, testing the relative effectiveness and proper fields of the didactic and the Socratic, individual and group presentations, demonstration versus case study and clerkship, the intelligent use of print, the picture both moving and still, the radio broadcast and short wave have as yet many untouched possibilities for the education of the physician. A health authority can therefore well afford to have an expert on teaching methods and an educational division bursting with ideas and schemes for the testing and utilization of the already known, and the development of the new and original in this field. I mean something immeasurably more serious thought out and purposeful than haphazard bursts of headlines and posterism, which are only the cap, bells, horn and megaphone of education. To meet the requirements of a new era we shall have to go far back into the childhood of the doctor into his common schooling, into his premedical years. We shall have to invade his leisure if such there is in his professionally active period, with new effort at more

Read before the Annual Conference of State and Territorial Health Officers with the Surgeon General of the U. S. Public Health Service, Washington, D. C., April 13, 1936.

intriguing informative reading We shall, perhaps, have to put journals beside the outhouse seat for studious and not substitute purposes We may even plan to reach under the car dash to install the short wave radio that keeps the first moving doctor constantly alert to the problems and control of disease as the police are informed of crime, giving him short wave broadcasts from medical research and public health centers and from state and national health authorities We shall have to make available not mere lecturers and exhorters but more and better individual consultant service—personal, telephonic spoken written On these, the merest scratching of the surface of education is the best that we can as yet show

THE "INFORMATIVE PROGRAM" AND LAY AGENCIES

There is a disposition these days to oppose as amateurish and presumptuous usurpation the lay organization's tendency to tell us, the medical profession, what to do, or to set about doing it for us Such reaction on our part is, to my mind at least, short sighted We have no monopoly of the brains that are applying themselves to problems of human health and welfare We cannot even reasonably seek a division with laymen along the line of body versus spirit for both are our concern and theirs We cannot claim the medical, demanding that they stick to the economic, for who that has practiced does not know that the two are inextricably and tragically one Let the health authority, then, begin with a cordial acceptance and furtherance of and eager cooperation with organized lay groups concerned with medical and medicosocial problems It extends our arm and weights our hammer, it steadies our plow in the furrow so to do It puts the power of money back of our ideas Of special moment to the venereal disease control officer is the furtherance of cooperation between physicians and groups that can educate for as well as act directly on the problem We should induce the special lay groups to 'take on a flier' in venereal disease education rather than discourage them The antituberculosis societies, the public health nursing, penologic and child hygiene organizations, health councils, social agencies, parent-teachers' and women's clubs are parts, not opponents, of the armament against venereal diseases Tell them frankly what is needed, what is lacking Do your best to induce the medical profession to lay aside its isolationism and join hands with them

Moreover, in three great blocks of business and professional activity the health authority has been much too backward in using its tact, its power and its prestige for an educationally and practically effective policy—the drug and pharmaceutical groups, the large-scale industries, and the life insurance organizations Through these three and the organized or socially employed nurses of this country, the whole face of the venereal disease situation could be changed as from behind a director's desk These groups, educated by us, have power in turn to educate personnel and clientele, and to extend education through patronage, the job, the purse

Education of the laymen who constitute the physician's clientele is an effective and permissible though not a preferred method of educating the physicians We as doctors are not and cannot all be leaders, all constantly and encyclopedically informed and effective all around our horizon How often are even the most alert among us first made sharply aware of an advance

in medical knowledge by a patient, who, in these days of spreading popular information, quotes us a clipping and sets us privately to looking up a journal number from which we have otherwise not yet ripped the wrapper? How many of us today learn from an alert medical reporter in *Time* or a syndicated column in a news sheet of the latest pronouncements and progress if not in our own, then in our next door neighbor's

field? The health authority is vitally concerned with the lay group's instruments and mechanism for the education of the doctor—quite as much concerned indeed as with the doctor's education of the lay instrument From the unintentional action of that mechanism we can learn and imitate

A SCHEME OF TEACHING METHOD

As I assembled my ideas for this presentation it occurred to me that a classification and summarization of the items and interrelations of educational mechanism in general might guide us in some applications to the venereal disease field Every agency, lay or professional, uses one or more of these education instruments on both the doctor and the everyday man I

therefore offer this tabulation as a vest-pocket tickler for thought rather than a finished product, and discuss it on the basis of thirty years of teaching experience

THE BASIS OF LEARNING

Human beings tend to be preponderantly either visually or auditorily minded, the former being substantially the more numerous group. Most people therefore learn from what they see better than from what they hear. Thinking is also a muscular and motor as well as a mental process. Association trains are therefore built up and fixed by conversion into action as rapidly as possible—by a laying on of hands, so to speak, familiar to us in the aphorism "We learn to do by doing!" What do these principles mean for educational method as applied to the physician? They mean that he usually learns least of all by listening to the didactic lecture. Aside from the fact that it deprives him of the mental exercise of synthesis, it requires all the devices of histrionic and rhetorical talent to make facts stick. More than half the effect is fogged by emotional content, with such primitive stuff as the appeal of sound to the ear and motion and gesture to the eye, rather than logic and intelligence to the mind. Reading of print outranks spoken teaching as an instrumentality because in making its appeal to the visual mind it acts more directly, with less emotional claptrap. Yet what is it that students, medical graduates and practitioners in their county, national or other societies are demanding today? They cry for and we offer them the lecture, the didactic discourse, the speaker, the "scientific communication" or paper, which, if it is not utterly muffed by being droned into the collar or spread as a musty soporific gas among the rows of weary sitters, must for effect be fired in a rat-a-tat-tat of staccato syllables accompanied by jerkings and jumpings, as wasteful of human effort as the two hundred or more rounds required to strike a significant target from a machine gun pill box compared with the solitary silent lethal bullet of the sniper in the tree crotch. Today's flood of printers' ink we so lament is as nothing to the deluge of wasted spoken words in which our educational effort flounders. I give it to you as an impression derived from many experiments in teaching method and the comments of many of my student cooperators and victims that good teaching is that which catches the eye and holds it, coordinates what is seen with touch and other senses and converts it into some form of muscular action, positive, investigative or consequential. Good teaching does one more thing as a final fillip: it arouses the learner with a prod or a challenge, which like the last turn of the screw press, imprints indelibly the image of the fact and its associations on the tables of the memory.

EXAMPLE AND CHALLENGE VS. PRECEPT

In teaching the doctor then example (visual) should outrank precept (audition). The graphic chart outweighs the words, the patient outweighs the chart, the personal performance of examination or treatment far outweighs in teaching power any mere visual device such as the witnessing of a demonstration. The demonstration outweighs the lecture because the witness sees things being done. If he is too far away to see and merely hears, he gets little or nothing—the explanation of the tedium and failure of the overcrowded society meeting and amphitheater clinic. Why cannot everything be done with the talking moving

picture then? you ask. Or cannot the visibility to accompany the spoken word be supplied by the silent film or the lantern slide? Because useful though their contribution to verisimilitude has been and can be, pictures do not live, and hence they do not give that challenge of which I just spoke. The difference is as between the synthesized protein and the living protein, so to speak—an as yet indefinable but essential something which involves the clash, the spark discharge that only the living draws from the living. Lacking the living challenge, by what other devices do we seek to inject the vital spark into teaching? Socrates, the father of education, laid the foundation of the dynamic technic of education in the Athenian groves by the use of the argumentative question. Across the otherwise dead body of the mere fact I, the teacher, challenge you, the student, to combat. By putting you on your mettle, I invoke a response from your emotional, your adrenal, mechanism—an abortive rage reaction to a challenge which makes the quiz discussion over the case, actual or hypothetical, the most effective teaching instrument in existence. It is effective because it is the method of life, which always questions rarely tells without a struggle.

Speech making and broadcast then is at its best when exhortative rather than informative. The most effective speech challenges rhetorically to action rather than coldly to reason. Great though the worth of exhortation is, all know how short is indeed the life of its message. A pure didacticism is in general, weak. When, therefore, lectures must be performed the chief instrument, let us carefully select the material for its ability to impress by throwing an actual or hypothetical problem at the learner in which he is challenged to performance. When does a student really begin to learn syphilology? Not when he reads a chapter on treatment but when the sweat drops from his perspiring brow onto the shaking hand that holds his first syringe. Until that moment, injection has been an unreality, given outline in his mind largely by the challenge of a feared examination, the caustic comment of his teacher. Even this much point to the spear is inevitably lacking in the didacticism of the average medical address, the society postgraduate course, the film, even the best written textbook. If my thesis has weight, it would be well then that the health authority should throw its influence into the educational scale in behalf of the visual and combined methods of the table over purely auditory teaching, that it encourage and develop clinic and case study and the fixing of knowledge by personal examination of the patient, manipulation, procedure technic, contact with the expert in a consultative capacity over the patient, rather than mere discourse, spoken or written.

RADIO, PICTURES, PRINT

Examined in the light of these considerations, then I would rate the standard radio broadcast as at once the weakest and the most diffuse of informative methods in our field suited to exhortation and arousal rather than instruction. As a didactic method with no eye appeal it demands of those who use it an exceptional command of challenge devices in voice, rhetoric and technic of material arrangement and presentation if their stuff is to stick. The mere ability to speak words would not then make a successful radio teacher. How often the actual demands are

met by the radiators from our field who address their collars or reading desks instead of the "mike" through a rattle of memorandum sheets and a barrage of "ums" and "uhs," you must yourself decide. Doctors, long suffering though they are in their eagerness for crumbs of knowledge, will turn from an attempt to teach them that denies them even the humor-arousing spectacle of the tortured speaker gasping in the dust cloud of his own remarks. Yet radio, I am convinced, can be made a useful instrument of postgraduate medical education, if only it is skilfully employed.

Of pictures, still and moving, I can only say that years of medical barnstorming and experiments performed in my own classes have convinced me that they are beguiling but comparatively ineffective. Audiences like them for the eye appeal and because they spare thought. I rate them today as suitable largely for addresses after dinner, to keep one part at least of the audience conscious, and to allow the other portion to sleep without annoying or too seriously disturbing the ego of the speaker, on which his delivery so largely depends. As teaching devices, slides have a comparatively small return in fact retention and utilization. A thousand dollar collection of my own now stands idle when I have intensive teaching to do. But these strictures apply less forcefully to the good textbook illustration or diagram, which can stand before one until one is forced to absorb its meaning.

In the matter of print, I believe that we should play up to the student and the doctor, inevitably largely dependent on it as they are, much more than we do particularly in the ingenious use of typography and systematized arrangement to set out and drive home the high points of factual matter. Thus I use one-two-three presentation, mnemonic devices, alliteration, sloganization, blocking, line set-offs, adequate face differentiation of title, content and special emphasis in all my teaching work. While emphasis may be overdone, the monotony and drabness of medical textual presentations is conspicuously wasteful of teaching energy. Text can be given some of the snap and emphasis of diction. The results of a lifetime of hard thinking and hot living need not be ironed down to the same dull gray of formless type as a count of the micrometer length of paramecium in a hay culture. There is no resultant benefit to the measurements or their significance, and there is a rape of emphasis and artistry in the former which seriously reduces its teaching value. Just as typography was used by the monks to convey beauty and spirit, so today it can be used to convey logic, system, cogency and power.

It should be accepted as a general teaching maxim that anything that can be merely said should as rapidly as possible be brought to print, for from that point teaching can move forward to the more vital discussion of the printed principle and its applications to real life. It is not for nothing that the unexpected discussor from the country who rises in the row of nonentities at the back of the room to drag back your paper to reality begins with "I had a case." In that remark lies the alpha and omega of medical education for the everyday doctor, for he thinks by the case. Let us then, in the "informative program," take this to heart and lean as heavily as we can toward the case lead or attack on our teaching problem, which means essentially demonstration, conference, consultation, clinic, rather than broadcast, lecture, picture, print.

EXAMINATION AND QUIZ

The examination and the quiz still to my mind stand in a place of their own among the major agents for the impression of knowledge. In this opinion I follow the men who have advanced Europe's venereal disease informative program among physicians well beyond our own. I grant you at once that there are certain persons who can pass certain kinds of examinations without evidencing thereby an atom of integrated knowledge or ability to apply it, and some that cannot pass an examination who none the less are intuitive wizards, exempt from the ordinary rules that govern logic-bound minds. But for the large majority, the questions that first our teachers, then state authority, then life itself puts to us are commanding challenges to the mastery of at least enough to pass. With the machinery of examination, therefore, the public health authority is inevitably deeply concerned. It cannot afford to leave to a sense of duty or self interest the physician's acquiring of a knowledge of the principles and technic of control of an infectious disease. Ipso facto the forward looking health authority, knowing that the practicing physician holds an essential place in his personnel for venereal disease control, will seek a contact first with the medical school, to secure adequate instruction in minimal essentials and adequate undergraduate examination by its faculty, and second with the state licensing authority to be sure that, if one fails to check or to stimulate the incompetent, the second will detect and stop him.

THE CURRICULAR OR FORMAL EDUCATION OF THE PHYSICIAN

The equipment of the physician for comprehension of the venereal disease problem should begin, allow me to insist, in the common schools, indeed, at his mother's knee. The unfitness for the demands that all sex-linked problems make on character and human insight, which one cannot but see in too many medical students and practitioners, can be dealt with only by a process of education in general and sex education in particular, which should begin in the early years of life and through such schooling as pioneers like Beatty of Westchester County, N. Y., have here and there developed against opposition and penurious educational policy. The health officer can be none other than a social hygienist. Inevitably, therefore, in behalf not only of the public but of his physician cooperators, present and to come, he must inquire into and concern himself with this phase of education. I make this statement the more emphatic because you as well as I can recall the day when the social background of syphilis and gonorrhea was considered a mere side issue, the affair of a tender-minded group of hush-hush pussyfooters preaching the unco guid of continence and the marriage vow a safe distance behind the hardy skirmishers and marchers of the public health syringe brigade. Today the mistaken social criteria still applied by physicians to venereal disease problems, the *noli me tangere* attitudes, the noncooperation, the refusal by the physician of the opportunity and duty of personal and public education, the ignorance of sex psychology and hygiene and the tacit acceptance or active advocacy of false public policies like legalization of prostitution, are dyed in the wool miscomprehensions and perversions of outlook remediable only through the general mechanism of education. For their persistence we shall be in part responsible.

PREMEDICAL EDUCATION FOR VENEREAL
DISEASE CONTROL

If it will take sex education as such, through the adequate human bodily hygiene course as well as a general biologic training in the common schools, to make the physician a comprehending human being, it may well take some decided changes of emphasis in his premedical education to make him an adequate counselor, a preventionist, a humanist, a leader, and a cooperative and intelligent student and participant in the program of the state with reference to health and disease. The public health authority can well afford then to study the equipment of the college-degreed medical school entrant, who must as a physician deal with and "inform" the candidate for medical examination before marriage, recognize the moron carrier and spreader of venereal disease, sympathetically grasp the juvenile sex problems of the school and the street, and cooperate and advise in the field of abnormal and normal psychology, sociology and educational method and principles. Is there not perhaps a little excess emphasis on languages, physics, chemistry and mathematics, and neglect of the studies that help to make the humanist? On just such forward looking thought as this with regard to the premedical collegiate years depends the sort of ground you will have to till in the public health campaigns of the 1940's and the furrow-driving capacity of your medical plowman.

MINIMAL ESSENTIAL MEDICAL INSTRUCTION

With the medical student as such begins the problem of the inculcation of minimal essential knowledge and the differentiation of education on the basis of the student physician's special interest in the field. It is time for the health authority to join actively with medical faculties in decisions and plans for a basic required course in venereology. Speaking for the syphilis side of it, in a recent plan for curricular revision the Department of Dermatology and Syphilology of the University of Pennsylvania proposed the division of the undergraduate work in syphilology into required and elective material, with time requirements and field coverage which I believe are fairly representative of the minimal teaching needs of the public health movement against syphilis as I see them. This contemplates two consecutive teaching hours (clinic) once a week for one semester and two two-hour sessions of practical work a week for six weeks, obligatory for each member of the third year class. The work of the fourth year is purely elective. This minimal essential or required course includes about 250 pages of text and from eighty to 100 actual patients, who are presented before the class by 160 student examiners. In the technical teaching sections the student personally witnesses the demonstration of *Spirocheta pallida* by darkfield, the collection of specimens for examination and mailing, the technic of precipitation and complement fixation tests, draws blood seers and mixes or prepares for injection the more common arsenical and heavy metal preparations and practices the technic of intravenous and intramuscular injection on specially devised manikins plus a patient or two for the more proficient. Two hours is devoted to a discussion of contact tracing, follow up and social aspects by the chief social service worker.

Such a program covers

1 The course of the disease. Most practitioners of today are grievously ignorant of its essential features and mechanisms.

2 The use of central facilities for performance, and the principles to be used in interpreting laboratory procedure and results in diagnosis and treatment.

3 The general principles of treatment.

4 The principles of control of infectiousness.

5 Technic, intravenous, intramuscular.

6 Reaction prevention and control.

7 A system for early syphilis and prenatal syphilis.

8 Practitioner's management of latent and late syphilis, with don'ts.

9 Social and state responsibility and control.

For the senior elective work, which in my experience will attract one in each four or five members of our classes, is reserved the actual mastery of darkfield technic, the differential diagnosis and intricacies of syphilis, consultation problems and treatment prescription.

It will be noticed that the average student is not taught the use of the darkfield or the performance of any test. The providing of the facilities for such laboratory procedures is your problem, just as with gonococcus smears and diptheria cultures, and the student is taught that it is your problem, or that of a laboratory specialist, and to demand such service of you. He merely learns to secure the material for examination. He is taught what to expect of you, how to check and control you, how to criticize you and himself, and how to interpret the result you report to him. You will notice, on the other hand, the emphasis on treatment technic and the prevention of trouble. Nothing is more important, for the whole structure of modern syphilis control rests on treatment technic. A schedule can be set down in black and white, but the patient is actually treated by adequate technic and skilful trouble-shooting. The emphasis on them is justifiable, for without them patients do not carry through to infection control and cure. Moreover, the intravenous and intramuscular technics used in syphilis treatment are essential to all medical procedure and the time spent on them is part of general medical education. Nowhere in the medical practice of today is ignorance more woful or the patient more abused than in commonplace procedure. The manikin is important, for the attempt to teach technic on the human subject wholesale in outpatient clinics and hospitals means wholesale default and lapse in treatment among patients who will not tolerate painful and reaction-producing mishandling by students.

Three other items deserve to be added to the field of the minimal essentials instruction in the strict following of advice from a consultant source, a hard thing for the medical individualist to learn, knowledge of where to find facts and how to distinguish fact from buncombe, and knowledge as to how to keep up to date. On all three we teachers would like to refer as sources to a well organized and effective state as well as national health authority and such now well established agencies as the Cooperative Clinical Group and the League of Nations Health Organization their personnel and publications.

Minimal essential knowledge for the student and physician being thus defined, the public health authority should everywhere extend cooperation and make every effort to make the material and teaching of such a course available to every graduate practicing physician who may diagnose or treat syphilis. As an example of what might be done I recall a winter course organized recently by two local medical groups in a large city. It followed an unwelcome but evident

challenging discussion by an outsider under the auspices of a council of social service agencies on the part physicians were not playing in venereal disease control. The course as presented was voluntarily organized by local medical groups and followed surprisingly closely the leads of this outline. It could be reduplicated today by many institutions and medical organizations under public health leadership. It could be offered by clinic and teaching hospital organizations, and it could be adapted to interns, whose conspicuously deficient instruction in syphilology has just been aired by Clarke and Eaner. It requires at most not over fifty-six hours of instruction, which under pressure might be reduced to forty or even less for smaller groups that can be brought closer to the patient and the equipment—two hours a day for less than six weeks, half time for two weeks, full time for one week, and two and a half hours a week from October to February or February to May. Such courses can be ideally given in large cities with medical and teaching centers.

THE CULTIVATION OF SPECIAL INTEREST

Since it is to be understood that there are those both in and out of school who will for lack of interest never master or employ even minimal knowledge in this field regardless of opportunity or pressure, we should reinforce ourselves against their indifference by the cultivation of special interest wherever possible. The specially interested student and doctor are the material of that large informal body of venereologists, from ten to fifteen thousand at least, which treats 60 per cent of the cases of syphilis and gonorrhea. They are, moreover, the recruiting ground of the health authority's own venereal disease personnel. It is time to do away with the uncomfortable undercurrent of opinion that when a man comes back from the war or can get no other job he goes into venereal disease work. Here I am sure the health authority has, then, an opportunity. It should seek to learn the names and intentions of those who, even by applying merely for a student elective in syphilology, show a leaning toward venereal disease problems. Hospital interns and men training themselves specially for venereal disease and associated fields should be objects of personal solicitude to health authorities who appreciate how much a trained and interested personnel contributes to accomplishment. A contact officer or a contact bureau or division in the national service at least, equipped with cards, maps and follow up, should be, as Becker once suggested to me, constantly on a still hunt for eligible men from students and interns to practitioners and clinicians, to be developed into local consultants, interested cooperators, clinic aides and chiefs. When these men enter the hospitals or settle in the towns of your states, give them welcome and substantial official encouragement and support from the start.

SUMMARY

One would wish, did time permit, to give some discussion to the training of the specially interested medical student by electives, the opportunities to be developed for the equipment of the semispecialist in whose hands is more than 60 per cent of the venereal disease treatment of this country, the specialist in venereology as distinguished from syphilology or urology, the worth, possibilities and as yet ill supplied need for authoritative consultant knowledge, available

under all the categories covered by this word in the table. One should critically consider too just what the education of the man now actually out in practice lacks in this field and how those lacks can best be met—whether by exhortations and “informative” addresses, by group meetings of already constituted societies, or of special institutes organized by the public health authority, or rather, as I feel, by the development of peripatetic but none the less adequate field teaching personnel, which, equipped with the stuff and the knowledge, goes to the doctor by auto, train or truck as he faces or bends over his problem and shows him, with the case before him, how and why. I could devote several more pages to special technics for “putting knowledge over,” such as the slogan, the sharp telling phrase that makes facts stick. And I could talk long and seriously about the impending dangerous influx of half-baked, undertrained men, neither adequate venereologists nor competent public health officers, who will besiege you and insinuate themselves into key positions as funds are allocated to venereal disease control by state and national governments. An adequately equipped man for your work can hardly be the product of less than a year of full time in an organized teaching clinic—and top positions carrying consultant responsibilities demand two or three years. I cannot urge you too strongly to be exacting and critical of the equipment and training of men to be taken into your organizations at this most important time. Mere personableness and connections will apply and, if accepted, set your clocks back a decade or two—and more.

But I believe that if I can induce you to look back over the principles I have set forth, and you find them acceptable, you will be able for yourselves to examine and select methods suited to special situations. You will then see that I lay emphasis on training the young rather than the old, on case teaching rather than lectures and slides, on socratic quiz and challenge rather than didactic teaching, whether before classes, in books or over the air, on a field teaching force which meets individuals in consultation over the patient, on the brush-up group working intensively at doing things in a teaching clinic rather than at merely hearing things anywhere else. Is it right or necessary that the “Voice of Experience” in the field of mental health (which by the way, uses the case method) should occupy almost acres of space in a great modern office building answering questions, when beyond an occasional query and answer column and a scattering of overdriven consultants there is no equivalent mechanism for helping the average doctor confronted with the greatest infectious disease problem of today directly out of his quandary over “the case”? What would it mean to you in such a situation, if without a sense of imposing on some one and as a legitimate function of the state's cooperation in your individual practice problems you could wire, ring a number or write, and get something personal and really helpful done within a few minutes or hours about a treatment schedule, a reaction you can't control, an infection being passed along while you stand helpless, a drug that won't do what the book says it will? If you will think thus, I am sure that you will think more clearly and in the end more economically, and more directly to the point, on medical cooperation and education in the problem of venereal disease control.

THE CIVILIAN EDUCATIONAL PROGRAM IN THE CONTROL OF SYPHILIS

N. A. NELSON, M.D.

Assistant Director, Division of Communicable Diseases, Massachusetts
Department of Public Health

BOSTON

Maimonides, the great Jewish philosopher and physician of the twelfth century, wrote that success is the synthesis of four elements—good material with which to work, a good plan according to which it may be fashioned, good technic in the execution of the plan and, finally, a good objective. Perhaps there may be found in this philosophy a formula for the development of a successful program of civilian education in the control of syphilis.

The objective has been identified. Is it a good one?

Syphilis, like gonorrhea, may have had its origin in antiquity. It is certain, however, that it has enjoyed universal prevalence since early in the sixteenth century. Unfortunately, its recognition as an almost epidemic disease came at a time when public morals were such as to facilitate its rapid spread and to fix attention almost exclusively on its relation to sexual promiscuity. It soon became the badge of loose morals. This acceptance of syphilis as invariably the offspring of iniquity remained unchallenged until a tidal wave of prudery made challenge futile by burying sex itself in the depths of its tabu.

So thorough was the burial and so potent the tabu that until recently few persons outside of medical or social hygiene circles dared say either sex or syphilis. The physician is still by no means rare who declines to treat the disease because of its moral implications. The health officer is unusual who does not resist the intrusion of the control of syphilis into his heretofore "uncontaminated" program. The employer promptly kicks into the street the employee whose "positive" blood makes him doubly undesirable as obviously immoral and disgustingly diseased. The educator is horrified to whom it is suggested that syphilis is worth study as an economic and social and health problem. The editor fatuously insists that he must "protect the newspaper-reading public from the indecent," and the Columbia Broadcasting System, rather than permit the mention of syphilis, puts the commissioner of health of the state of New York off the air.

Fortunately, however, there are always those in whom the urge to know the truth cannot be denied. Such ones distinguished between syphilis and gonorrhea in the nineteenth century. They discovered *Spirochaeta pallida*, developed the Wassermann test and synthesized arsphenamine all within a decade early in the present century. They have learned that among all communicable diseases syphilis is one of the most dangerous, most costly and most prevalent and that the majority of infections occur between the ages of 15 and 30 years. They know that if discovered in time the disease can be cured and its communicability quickly controlled, that the number of innocent infected women and congenitally infected children is legion and that innocent infections are avoidable and congenital syphilis utterly inexcusable. They are sorely burdened with the knowledge that the sum total of misunderstanding and misery and injustice which has arisen out of public

ignorance of syphilis is beyond imagination. They believe that it is high time that people were told the truth about this disease which so vitally concerns them.

The development of a good technic for the fashioning of a program of civilian education in the control of syphilis deserves serious consideration. A logical first step might be the education of ourselves who propose to be the teachers of the public. How well are we prepared to teach?

Have we added so much to our own knowledge of syphilis that our own attitudes toward the infected are any more wholesome or tolerant than the attitude of the public we would educate? Have we, as health officers, learned as much about syphilis, in proportion to the information available, as we have about smallpox, diphtheria, typhoid fever or tuberculosis? Are we so enlightened that we welcome the challenge of syphilis or do we secretly resent the appearance of this "immoral" intruder? Are we willing to fight for appropriations for the control of syphilis with the same vigor and persistence with which we have fought for appropriations for other health department functions?

Are we annoyed by the realization that in order to prevent innocent infections, we shall be obliged to spend time and money for the enlightenment and encouragement and decent treatment of the guilty? Are we inclined to rush to the police for assistance in returning a patient to treatment, thus making disease a crime, although we would resent the suggestion that we needed police assistance in the control of any other communicable disease?

Are we able to appreciate that, although sexual promiscuity is an epidemiologic factor in the spread of syphilis, it must not prejudice our approach to the problem of controlling a disease which is dangerous to the public health? Do we think of syphilis as a "venereal" disease? If we do, how do we propose to convince the public, to which venery is synonymous with lasciviousness, that syphilis is altogether too often not a venereal disease?

Have we pulled ourselves out of the mire of misunderstanding and ignorance and prejudice that we may lead others to more solid ground, in a higher and cleaner atmosphere? How otherwise can we declare, with any sincerity, that we propose to develop a program of civilian education in the control of syphilis? How otherwise can we believe that our technic will be good or that the objective is good?

It should not be necessary to worry much over the plan according to which the material may be fashioned into a program. Experience should have taught us by now, if it ever can, what the channels are for public information and education.

Attractive literature (with emphasis on its attractiveness), in abundance both as to quantity and variety, talks to public audiences whenever the opportunity presents itself, exhibits wherever they may suit the audience and whenever there is time for their study, moving pictures when the price permits and the returns are worth the cost, radio talks, dramatizations, press releases—these are the plan. We know them; we have used them; they are there to be used again. There is no magic or yet to be discovered channel through which the public may be taught to know syphilis.

It is evident of course that certain groups should have special attention in our plan. Syphilis is acquired largely by youth. It is transmitted by uncleaned groins to innocent brides. Congenital syphilis is the product of untreated syphilis in pregnant women. The ravage

of late syphilis are of the greatest economic importance in that part of the population which is over 30 years of age. The employer will not tolerate syphilis in the employee. School teachers labor under the misapprehension that congenital syphilis is forever communicable and invariably disgraceful, to the sorrow of the unfortunate child. Of these groups, therefore, a good plan will be particularly heedful but what program of health education does not need modification to meet the requirements of a specific problem?

It may not be safe to complain too bitterly that the radio and the newspaper are not freely open to discussions of syphilis. It is possible that if every radio station and every newspaper (or even one station and one newspaper) should call our bluff by opening its microphones and offering its pages to us tomorrow, we should be caught with nothing in our hands. Material is essential to a program of health education. The radio and the newspaper will become available with time, with proof that public condemnation does not follow, and with evidence that we have something sound and sensible to say. No educational program ever sprang into full-fledged being over night.

It would seem that, if Maimonides knew what he was talking about, success must be well within our grasp. Our objective is good. A good technic may be developed if we will but avail ourselves of knowledge that is ours for the taking. A good plan is in our hands. But what of material, if I may define material somewhat narrowly as that knowledge which has been put into form suitable for presentation to the public? There's the rub! There is no material!

The Massachusetts Department of Public Health has produced, reprinted or purchased a total of more than 800,000 copies of fifty brochures on gonorrhea and syphilis during the last seven years. Thirty of the fifty are of interest only to the physician or medical student. Fifteen are addressed to the nurse, social worker and health officer. Three are for the information and instruction of the patient. Only two are devoted to public education, and, as I wrote them myself, I can say that they are nothing to be particularly proud of.

Good medical papers are relatively easy to find. It is not too hard for a health officer who believes in his subject to prepare something of interest to other health officers. The idea, rather than the style, is of first importance in a technical paper. But few of us have the happy faculty of being able to write interestingly for the public, and fewer of us know enough about syphilis to write anything at all.

I have yet to discover the story of syphilis (or any part of it) written in such a way that it could be used by the health department and would arouse the interest of the man in the street. There may be such material somewhere, but neither have I been able to find it nor do I know of any agency that might have discovered it for me. I should like to buy some, since I cannot produce it. The average health officer will need all the assistance he can get from some central collection and production agency (such as the National Tuberculosis Association in its field) if he is to acquire material for public education in the control of syphilis.

If any one of us were granted an appropriation tomorrow for the employment of a single sane and unemotional lecturer who knew anything about syphilis, where would one be found? I would like to borrow half a dozen radio talks on syphilis which are not dry and uninteresting tables of statistics, or emotional

eruptions on sex, or too vivid descriptions of the anatomy involved or the too frank discussion of the unpleasant signs of the disease. Who has them to lend? There is neither material nor any one with both interest and ability to produce it.

Finally, some decision must be made as to the part which the health department is to play in the development of the broad social hygiene program. Whatever the decision, it will determine the content of the material to be produced.

The social hygienist would promptly repudiate the allegation that the primary object of the social hygiene program is the control of disease. He would define syphilis and gonorrhea quite simply as the more prevalent and identifiable signs of poor social hygiene. He would point to the unmarried mother, the prostitute, sexual promiscuity, family discord, separation, divorce, perversion, sex crime and a multitude of social ills as other symptoms of the misunderstanding and the misuse of sex. He would use legal measures and education for the control of the prostitute, protect the feeble-minded, lift the unfortunate out of miserable environments, provide ample and wholesome community recreation, prepare youth for marriage, give counsel to the married, and make sex character building as much a part of the education of every child as any other form of character building.

Obviously these objectives are so broadly social as to be far beyond the scope of a health department program. It is also evident that this is a long-range program, while there is much to be accomplished toward the control of syphilis by the immediate application of medical and epidemiologic procedures, which is a function of the health department.

However, preventive medicine is the keystone of the arch of public health. Case finding and treatment have accomplished wonders in the control and prevention of tuberculosis, for instance, but, in the long run, higher standards of living, better housing, good nutrition, more rest and recreation and more wholesome working conditions will not only help in the prevention of tuberculosis but make it easier to hold onto the gains that are made. The health department cannot be responsible for this long-range and broad program for the improvement of standards of living, but it can point to the relation between tuberculosis and poor standards of living, and it can encourage and support those who seek to improve those standards.

So it is with syphilis and the social hygiene program. It has been said that the difference between the European and American plans for the control of syphilis and gonorrhea lies in the fact that Europe puts the greater emphasis on disease control and America on social hygiene. There should be a happy middle ground.

Maimonides has defined the ingredients of success. There is not a good health officer anywhere who has not found them out for himself. To improve and protect the public health is every health officer's good objective. To learn what there is to know about a problem and to approach its solution without prejudice makes for expertness in technic. To use a well known and often tried plan, lacking a better one, is common sense. Good material is the product of knowledge and a desire to put knowledge to work. A program of civilian education in the control of syphilis is nothing more than a program in health education. Success in the control of syphilis will come to those who apply to the control of syphilis the age-old formula for success.

A minister was called on to substitute for another in a rural church. He took his small daughter with him. As they entered the door of the church he dropped a fifty-cent piece into the collection box. At the conclusion of the service, as he was about to leave, a vestryman approached him and said "It is the custom in this church to offer to any visiting pastor, as his remuneration, the day's collection. I regret that it is so small." He handed the minister fifty cents. Several minutes later, as, with his daughter, the pastor walked slowly out of town, the young lady broke the deep and gloomy silence with "Well, daddy, if you had only put more into it, you'd have got that much more out of it."

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
FRANKLIN C. BING, Secretary

THE NUTRITIONAL SIGNIFICANCE OF BRAN

Wheat bran consists of the outer coats of the wheat grain which can be separated from the germ and various grades of flour during the milling process. The commercial product usually contains some of the wheat embryo and a small amount of endosperm because of the difficulty of making a sharp separation. The bran amounts to approximately 12 to 15 per cent of the grain. It has come into prominence since the development of modern methods of milling, which date back to about 1870. At first it was used almost exclusively for feeding farm animals, but subsequently it was introduced as an item of the human dietary. From the standpoint of human nutrition, it should be mentioned that there are two principal varieties of bran on the market. Untreated bran is the mill product widely used for feeding animals and also, after cleaning, to some extent for incorporation into dough mixtures for making certain bakery products such as bran muffins. The prepared type of bran has been subjected to processes designed to improve its palatability, and it is distributed primarily as a so-called breakfast cereal food.

TABLE 1—Comparative Composition of a Crude and a Prepared Bran

| Component | Moisture-Free Basis | |
|--|---|---|
| | Crude Bran (Based on Report by Osborne and Mendel) per Cent | A Prepared Bran (Based on Report in THE JOURNAL, Feb. 9, 1935, p. 474) per Cent |
| Ash | 7.2 | 8.4 |
| Starch | 7.1 | 3.2 |
| Sucrose | 17.0 | 8.3 |
| Crude fiber | 1.6 | 14.3 |
| Carbohydrates other than crude fiber (by difference)* | 9.4 | 9.2 |
| | 69.3 | 7.9 |

* Osborne and Mendel found 27.6 per cent pentosan, 13.4 per cent starch and 4.2 per cent dextrin in crude bran, moisture free.

The processing may vary somewhat. The general procedure consists of washing the crude bran (sometimes with dilute acid, then with water) and mixing with malt syrup, sugar, salt and water. The mixture is cooked and finally dried and packaged. Frequently it is shredded or toasted before being packed in cartons.

The two varieties, crude and prepared bran, differ in their composition because certain soluble substances are lost during the washing of bran and other sub-

stances are added. A number of years ago Osborne and Mendel¹ reported an analysis of a crude bran product. Their figures, in table 1, are reported on the water-free basis. For comparison, published figures for a prepared bran product are also shown. They bring out a number of essential differences between the so-called breakfast food type of bran and the ordinary milled product. It may be noted that the amount of fiber which is present in the two products is somewhat less in the prepared bran than in the original material. Another difference not shown in the table between the commercial bran and the mill product is in the amount of phytin that is present. The washing process, especially if done with dilute acid, may remove considerable phytin from the original material. Phytin exists in bran as the potassium, calcium and magnesium salts of the hexaphosphoric acid ester of inositol. The significance of its loss can be appreciated when it is recalled that early investigators showed that cows fed on washed bran become constipated. However, Cowgill and Anderson² concluded from their work with men that the loss of phytin is of no significance as far as the laxative properties of bran are concerned.

Other differences between crude and prepared bran to which attention should be directed are the concentrations of sodium chloride and of iron. Salt is usually

TABLE 2—The Iron Content of Crude Bran and Prepared Bran

| Product | Moisture per Cent | Fe, Mg per 100 Gm |
|--------------------|----------------------|----------------------|
| Kellogg's All Bran | 6.4 | 15.3 |
| Post's Whole Bran | 8.8 | 16.4 |
| Crude bran | 9.8 | 9.5 |

added in the preparation of the breakfast foods and this accounts for the presence of about 2 to 3 per cent sodium chloride. The amount of iron in the prepared bran products is stated to be from about 17 to 25 mg per hundred grams.³ Crude bran ranks as a food rich in iron; it contains about 8 to 10 mg of iron per hundred grams of dried bran.⁴ Analyses performed in a university laboratory for the Council on Foods are reported in table 2. These figures show that the iron content of certain bran products as purchased on the open market is considerably higher than the amount of iron which is to be found in the mill product. Considering that there are few food products of vegetable origin which even approach the high iron content of crude bran, it is difficult to understand how the iron content of prepared bran can be almost double the iron content of the mill product. This raises the question of whether the iron content of wheat bran is exceedingly variable or whether iron is introduced in some manner during the processing treatment.

NUTRITIVE PROPERTIES OF BRAN

Interest in the dietary value of bran dates back at least to the days of Bunge. He showed that bread made from whole wheat contained about twice as much iron as ordinary white bread. These differences have been verified by subsequent analyses by other investigators and have been shown to be due to the presence of wheat embryo and bran in the whole wheat bread. Further evidence of the differential distribution of food sub-

stances in the wheat grain was afforded by the observations of Bell and Mendel⁵. They dissected wheat by hand and concluded from feeding experiments with mice that the vitamin B content of certain portions of the grain was higher than the concentration in the entire kernel. Later work has verified the observations that bran contains a higher concentration of certain food factors than does the entire grain. The discussion to follow will take up the available information regarding the nutritive value of the various components of bran as far as they have been studied.

(a) *Inorganic Salts*—Crude bran contains a relatively high percentage of ash. This ash is rich in phosphorus, which is present in the bran as phosphate esters of inositol and also as phospholipids and other compounds. Little significance has been attached to this fact, however, because phosphates can be obtained from many common articles of the human diet and there appears to be little possibility of a deficiency of this element occurring in the usual American diet. Moreover, washed bran may contain only one-tenth as much phosphorus as crude bran⁶.

The presence of approximately 3 per cent of sodium chloride in the prepared bran products has already been mentioned. This fact would have significance in the formulation of diets in which low salt intake is desired.

From the nutritional standpoint, the most important inorganic constituent of bran is iron. Attention has already been directed to the striking differences in the iron content of prepared bran products as compared with crude bran. Dr. Mary Swartz Rose, with her collaborators, has studied extensively the question of the utilization of the iron of bran as compared with other foods. Using a sample which contained 10 mg. of iron per hundred grams, Rose and Vahlteich⁷ found in assays with rats that the iron of bran was well utilized. Later Rose, Vahlteich and MacLeod⁸ showed that the iron of bran was somewhat more effective in the production of hemoglobin in anemic rats than iron-equivalent quantities of egg yolk and of liver. Good results were also obtained when anemic rats were fed whole wheat as compared with the results observed when a solution of the ash of the same amount of wheat was fed.

Subsequent experiments have shown further that the iron of bran is as well utilized as the iron of ferric chloride. In two subjects, both of whom were young women, Vahlteich, Funnell, MacLeod and Rose⁹ showed that the iron of bran was as well utilized as the iron of egg yolk. The amounts of egg yolk or of bran consumed by these experimental subjects furnished 3 mg. of iron daily. It required 58 Gm. of egg yolk and 15 Gm. of bran to furnish this amount of iron. It is apparent therefore that the bran used in these experiments contained approximately twice as much iron as the bran used in the earlier experiments with the rats.

(b) *Protein*—The protein content of bran averages about 17 per cent, which is about 50 per cent higher than whole wheat. Although the amino acid makeup of these proteins indicates a good nutritional value, Rubner early showed that the proteins of bran are

digested with difficulty. More recently Murphy and Jones¹⁰ studied the nutritive properties of the proteins of wheat bran. They found that young rats grew normally on dietary mixtures in which bran supplied all the protein.

Experiments on man were reported by Holmes¹¹ in 1919. He studied the protein digestibility of wheat bran when as much as 4 or 5 ounces was eaten. The coefficient of protein digestibility was low, being only 37 per cent when fine bran was eaten and 36 per cent when coarse bran was substituted. His experiments have been criticized because of the large amounts of bran consumed and also because the diets contained relatively small amounts of total protein. Funnell, Vahlteich, MacLeod and Rose¹² calculated from their experiments that the protein of bran was utilized by their subjects (young women) to the extent of about 50 per cent. It must be concluded that the proteins of bran are poorly utilized. Moreover, in the amounts that might ordinarily be consumed it is apparent that the proteins of bran can contribute but little to the daily protein requirements of man.

(c) *Vitamins*—The only vitamin known to occur to an appreciable extent in wheat bran is the vitamin B complex, and in particular vitamin B₁. As already described, Bell and Mendel⁵ showed that the vitamin B complex was differentially distributed in the wheat grain. In 1927 Plimmer, Rosedale, Raymond and Lowndes¹³ found that bran was about one fifth as rich in vitamin B as wheat germ. In 1932 Rose and her collaborators¹⁴ reported that a sample of commercial bran contained somewhat less vitamin B than an equal weight of whole wheat. They concluded "One ounce of whole wheat bread will furnish 63 vitamin units and 100 calories, one ounce of bran suitably prepared for human use such as has been used in this investigation will furnish at least 45 vitamin B units, but not more than 30 calories." The vitamin unit referred to was that of Chase and Sherman, in terms of international units of vitamin B₁, 1 ounce of the bran product investigated contains about 23 units. Thus it is apparent that although wheat bran contains vitamin B₁, it is not as good a source of this factor as whole wheat, wheat germ and many other food products.

(d) *Carbohydrates, Including Crude Fiber*—The most publicized components of bran are the carbohydrates, particularly the indigestible carbohydrates referred to as crude fiber. In the dried commercial product reported by Osborne and Mendel, there were approximately 17 per cent starch and dextrins, 27 per cent pentosans and 9 per cent fiber. As pointed out by Rose and her collaborators,¹⁵ true values for the carbohydrates are probably slightly higher than the figures reported.

About one third of the total carbohydrate, comprising the starch and dextrin, is digestible and therefore serves as a source of energy. The rôle of pentosans in nutrition has been reviewed by McCance and Lawrence¹⁶. These carbohydrates, chiefly arabans and

xylans, are of negligible food value because no enzymes of the alimentary tract are capable of hydrolyzing them. The same is true of cellulose, which makes up a considerable portion of the material called "crude fiber." However, bacterial action, which may convert considerable of the pentosans into volatile fatty acids, has less effect on cellulose. The latter when fed is recoverable to a large extent in the feces. Bran thus contributes bulk to the diet, and it was early recognized as having a laxative effect because of this fact. While the "bulk" is made up chiefly of indigestible carbohydrates, it is well known that substances other than "crude fiber" may contribute to the residues found in the stool.

LAXATIVE EFFECTS OF BRAN

The laxative effects of bran have been studied by several investigators. Only experiments on persons will be considered in this report. Cowgill and Anderson² compared the laxative effects of bran and washed bran in healthy young men. They found no differences in the two products when tested in fiber-equivalent quantities. The authors therefore concluded that the laxative effect of bran can be attributed to its fiber content rather than to substances, such as phytin or salts, which may be leached out in the manufacturing process. They found as a result of their feeding experiments that the ingestion of bran leads to an increase in the weight of the stools. When the diet was selected so as to be low in crude fiber content, the addition of bran resulted in an increased number of bowel movements daily. These authors describe as a condition of marked constipation one in which an average of about six bowel movements a week was produced. According to the review by Alvarez,¹ this statement might be questioned.

Cowgill and Anderson analyzed representative items of the control diets ingested by their subjects and compared the results of the fiber intake with the fiber content of the stools produced. It was shown that approximately 60 to 65 per cent of the crude fiber of mixed diets may disappear on passage through the alimentary tract. When bran was added, the weight of fiber that disappeared amounted to only 44 to 51 per cent. It is thus evident that the fiber of bran is more resistant to decomposition by bacteria in the intestinal tract than is the crude fiber of ordinary foods. It was concluded that normal men exhibit "satisfactory laxation" when their diet contains about 90 mg of fiber per kilogram of body weight daily. This amounts to a little over 6 Gm of fiber a day for an average sized man.

Later Cowgill and Sullivan¹⁸ reported further investigations on the use of wheat bran as a laxative in six men who were troubled with constipation. It was shown that in all but one of these cases the addition of bran was efficacious in overcoming the complaint. Fruits and vegetables as sources of bulk were found satisfactory in two subjects. Another subject, however, apparently presented the picture of "irritable colon." He was unable to tolerate coarse vegetables or bran but was successfully treated with agar. The authors pointed out that diets of common foods containing sufficient fiber to permit satisfactory movements in healthy persons may not do so in subjects troubled with constipation. They attributed this to the greater loss of fiber in traversing the alimentary tract of constipated subjects as compared to normal persons.

Experiments on men are not entirely conclusive as far as constipation studies are concerned. It is well known that women are more prone to become constipated than are men. It is interesting, therefore, to note that Rose and her co-workers⁹ have studied the influence of bran on the alimentary tract of healthy women. As a result of these studies it was shown that the addition of bran to a controlled diet produced marked increases in the total weight and dry weight of the stools.

In a recent paper by Parsons¹⁹ it is pointed out that the problem of fecal elimination is largely an individual one which is affected by many factors in addition to the amount of fiber in the diet. It is difficult to evaluate the results of her experiments as compared with other reports in the literature. The divergence of results indicates, however, the importance which subjective impressions may play in such experiments with persons.

It seems reasonable to conclude from the evidence available that the weight of the fecal material and the number of bowel movements daily are dependent largely on the bulk in the diet, and that in normal men and women and in some constipated subjects, both may be increased by the ingestion of suitable amounts of bran. It also appears to be demonstrated that the fiber of bran is more resistant to decomposition in the alimentary tract than the fiber of many ordinary foods. The number of daily bowel movements that can be considered normal, however, is still open for further investigation. There is evidence also that some foods, such as prunes and fruit juices, may exert an effect which cannot be attributed to fiber or bulk. It may also be pointed out that other components of the usual diet, such as carbohydrates and fats, may exert an effect on what Cowgill and Anderson have called "laxation." Finally it may be noted that there are no reports in the literature of controlled dietary studies showing the relation of bulk to constipation in children.

THE INFLUENCE OF BULK ON PROTEIN UTILIZATION AND MINERAL RETENTION

Indigestible carbohydrates in bran must be considered in relation to their effect on the digestibility of other proteins and on the retention of minerals. Mendel and Fine, for example, showed with dogs that the addition to the diet of indigestible material such as agar or bone ash resulted in an increase in the fecal nitrogen. This effect has been shown by others to occur in persons also. In explanation it has been suggested that the presence of bulk may retard proteolytic digestion, a greater amount of metabolic nitrogen from digestion juices, and so on, which escape reabsorption, is produced, the intestinal contents are propelled more rapidly and hence not as completely absorbed. Whatever the reason, it appears that the effect produced by moderate amounts of fiber on protein digestion, while definite, is slight.¹² With abnormally high amounts of roughage, such as might be found in certain Chinese diets, Adolph and Wu²⁰ observed a definite lowering of protein digestibility.

Whitacre, Willard and Blunt²¹ found that the addition of fiber in the form of vegetables had no effect on the utilization of dietary fat. Morgan²² studied the

effect of the ingestion of moderate amounts of a cellulose preparation on young women. She found a slightly increased excretion of fecal nitrogen and a definite increase in the excretion of phosphorus, calcium and fecal ash. She questions the wisdom of giving a high roughage diet to children or to older persons under conditions of a marginal intake of calcium.

DISADVANTAGES FROM THE USE OF BRAN

In addition to the effect of bran on calcium excretion, there are other possible disadvantages to its use which demand thoughtful consideration. To many individuals bran is irritating to the mucous lining of the intestinal tract. It is self evident that bran or other rough foods may do serious injury if included in the diet of patients who recently have undergone operation of the stomach or intestine or who suffer with ulcer, carcinoma or other organic disorders of the gastro-intestinal tract. Patients with such conditions occasionally develop constipation. Also at times patients with ulcerative colitis of amebic or bacterial origin develop constipation. If under any of these circumstances bran is resorted to as a means of relieving the constipation, the previously diseased tissue will be irritated with results that may be disastrous.

It generally is less well appreciated that the constipation of many otherwise healthy individuals results from spasticity of the colon and under these circumstances that bland diets are more effective in controlling the constipation than is any rough, mechanically irritating food like bran. In such cases bran may so intensify the spasticity that obstruction necessitating mechanical or even surgical removal may result from its use.²³

It is the experience of many physicians that otherwise normal persons who suffer from constipation due solely to inadequate bulkiness of their diets will develop irritable colons if bran is taken in excessive doses for a short time or in ordinary doses continuously for longer times.²⁴ Vague abdominal pains occur, associated with bloating, belching and excessive flatus, these symptoms promptly disappear when the ingestion of bran is discontinued.

Danger from the use of bran is greatest when constipated individuals eat bran, and, not obtaining relief with small portions, take larger quantities of this rough, mechanically irritating food. The indiscriminate use of bran without the supervision of physicians therefore is undesirable. While many constipated persons without any digestive disorders may be benefited by the addition to their diets of bran in doses that are not excessive, alternating the use of bran with agar and other allied products or the provision of diets containing an adequate amount of residue less coarse than bran is considered to be a more desirable therapeutic procedure.

GENERAL DECISION ON ALLOWABLE CLAIMS FOR WHEAT BRAN

On the basis of the evidence reviewed in the foregoing report, the Council on Foods has considered the place of wheat bran in the human diet and has adopted the following general decision:

1 Bran may be useful as a source of bulk in the diet. The position of the Council in regard to "Constipation Statements in Lay Advertising for Roughage Foods and Bran" (THE JOURNAL, Nov 5, 1932, p 1605) is reaffirmed. Any reference in labels or advertising directed to the public regarding the content of bulk or crude fiber cannot be permitted unless there is repro-

duced the complete statement in the Committee Decision referred to, regarding a permissible claim for a roughage food. This statement is reproduced as follows:

Constipation due to insufficient roughage in the diet should yield to eaten regularly. A competent physician should be consulted for cases not corrected in this simple manner.

It is not permissible to advertise the use of bran in the treatment of constipation "due to insufficient bulk." This statement by itself encourages self treatment, which may cause harm in those persons for whom bran is contraindicated.

2 The iron content of untreated bran is high. Special claims for bran as a source of iron in the diet cannot be recognized, however, until definite evidence is obtained and accepted by the Council to show that the iron of untreated bran is available to the human body and, in the amounts which might ordinarily be ingested, contributes an appreciable portion of the daily requirements.

If iron salts should be added in the preparation of bran for human consumption, the presence of added iron should be declared on the label, in accordance with present regulations of the Council requiring a complete list of ingredients and quantities thereof entering into the product in the case of food mixtures or compounds.

3 The amount of vitamin B₁ in bran is insufficient to permit any special claims therefor.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C BING Secretary

ADVERTISING LEAFLET "MILK FOR ALL"

Sponsor—Evaporated Milk Association, Chicago

A leaflet prepared for distribution by welfare agencies. It is proposed to print part of the run of pamphlets in Italian. The leaflet contains a statement of the nutritive value of evaporated milk, suggested food selections in planning low cost meals, and evaporated milk recipes.

DR. PHILLIPS PURE FLORIDA GRAPEFRUIT AND ORANGE JUICE

(WITH ADDED CANE SUGAR)

Manufacturer—Dr P Phillips Company, Doctor Phillips, Fla

Description—Canned Florida grapefruit juice (60 per cent) and canned orange juice (40 per cent) sweetened with sucrose and retaining in large measure the original natural vitamin content. The same as Dr P Phillips Pure Florida Orange Juice (With Added Cane Sugar) (THE JOURNAL Dec 3, 1932, p 1948) and Dr P Phillips Pure Florida Grapefruit Juice (With Added Cane Sugar) (THE JOURNAL, Jan 7, 1933, p 43).

GOLD-PAK BRAND GRAPEFRUIT JUICE (SUGAR ADDED)

Manufacturer—Ariz-Sweet Grapefruit Growers, Ltd., Peoria, Ariz

Description—Canned Arizona grapefruit juice, with added sucrose, retaining in high degree the original vitamin C content. Same as Ariz-Sweet Brand Grapefruit Juice (Sugar Added) (THE JOURNAL, July 25, 1936, p 283).

Claims of Manufacturer—Intended for all dietary and table uses of grapefruit juices. Practically equivalent to fresh juice in vitamin C.

"SUBENON" FOR ARTHRITIS AND THE AMERICAN CHEMICAL SOCIETY

For several years the annual sessions of the American Chemical Society have been accompanied by extraordinary publicity in the lay press concerning new chemical discoveries applicable in the field of medicine and particularly for the treatment of disease. Each year has seen several disappointments associated with the subsequent fate of the widely heralded remedies. Occasionally, of course, some of the preparations thus announced have found a certain field of usefulness. The medical profession has thus far refrained from criticizing this interference in its field. This year, however, even before the opening of the annual session of the American Chemical Society, newspapers throughout the United States carried a story, emanating apparently from the publicity department of the American Chemical Society, indicating that a new specific had been developed for the treatment of rheumatism and arthritis. Some press associations which have been consulting the headquarters of the American Medical Association relative to press items in the field of medicine immediately made contact with authorities in the headquarters office to determine whether or not these stories were well founded. The item submitted to the press stated that "a compound which curbs arthritis, economically the most devastating of all chronic diseases, was reported by Dr. Herman Seydel (President Seydel Chemical Co., Jersey City, N. J.)." It was said that "the new compound, involving the medicinal application of benzoates, has proved effective in clinical tests covering two years at the Jersey City Medical Centre." Furthermore, Herman Seydel, Ph.D., reported that "in this calcium double salt of benzyl succinic and benzoic acids we offer the solution of an age-old problem. It remains for the medical profession to adopt it and employ it properly." Thus the speaker to appear before the American Chemical Society put the medical profession of this country squarely "on the spot" with a demand that it use his proprietary remedy. The item was of course much more extensive, proceeding finally to the

rather humorous point at which "Dr." Seydel pointed out that his remedy worked "by treatment designed to better the body humors." He explained "humors" by pointing out that "some modernists in medical science substitute for the 'humors' the 'bacterial flora of the intestines'." If this is science, Heaven help the scientists!

The real explanation of the usefulness of his product seemed to be, according to "Dr." Seydel, "the role played by benzoic compounds in the detoxication processes of the body" since it successfully removes waste matters from the body humors and is itself eliminated as either hippuric acid or a hippuric acid derivative. Hence benzoic compounds should have a decided advantage over other compounds in the treatment of conditions that arise from, or are controlled by, the gastro-intestinal tract. The secret behind this is, of course, the fact that the Seydel Chemical Company is a manufacturing organization which specializes in the manufacture of "benzoic compounds."

Naturally this extraordinary announcement in the press stimulated a flood of inquiries addressed to the American Medical Association, the American Chemical Society and "Dr." Seydel personally as to where this new specific might be secured. At least one inquirer was told over the telephone that the product could be secured by calling for it under its proprietary name—Subenon¹—at any of the establishments of a widely known chain of drug stores.

In his statements "Dr." Seydel mentioned a favorable experience with the treatment at the New York Postgraduate Hospital. The superintendent of that institution, W. B. Talbot, telegraphs:

We protest reference to New York Postgraduate Hospital in newspaper report of Herman Seydel. Stop. We used experimentally his product subenon but found it useless in arthritis. Stop. No favorable reports given out from this hospital about subenon.

Had the publicity associated with "Dr." Seydel's exploitation of his product gone directly from the Seydel Manufacturing Company to any of the better press associations or newspapers of the United States it would promptly have found itself—as merely a sheet of advertising material seeking for free publicity—in the editorial wastebasket. As it came to newspapers with the sponsorship of the American Chemical Society, a well known organization presumed to be composed of scientific men subject to the usual ethics which control scientific workers, press associations and newspapers cannot be condemned if they failed to recognize the definitely commercial background and effect of this item. Neither can thousands of unfortunate sufferers from arthritis be condemned if in response to this

¹ Subenon is claimed to be a calcium double salt of benzyl succinic and benzoic acids. In November 1935 Seydel declared his intention to submit the product to the Council on Pharmacy and Chemistry. The product was already commercially available at that time. It is rather before either new or of established value—facts which the American Chemical Society might have taken into consideration before permitting widespread exploitation under its sponsorship. The product has not yet been submitted to the Council.

item they demand of their physicians that they be given opportunity to test this unestablished drug. But in these circumstances the sufferer from arthritis is the guinea-pig and "Dr" Seydel and his company are the financial gainers with the American Chemical Society as their unpaid agent.

When the item appeared in the newspapers a telegram was sent by the Director of the Division of Drugs, Foods and Physical Therapy of the American Medical Association and by the Editor of *THE JOURNAL* to the president of the American Chemical Society pointing out the circumstances involved in this case and protesting the use of the American Chemical Society for aiding the premature and unethical exploitation of this proprietary. It was suggested that proper officials remove the paper by "Dr" Seydel from the program of the American Chemical Society. This, as we go to press, the president of that society has refused to do. The American Chemical Society cannot dodge its responsibility in this case. It is neither within its province nor within its competence to give critical judgment on the treatment of disease. If it wishes to maintain the respect of the medical profession and the public, the American Chemical Society cannot permit itself to be used as an agent for unestablished proprietary remedies in the exploitation of the sick.

ACNE AND CARBOHYDRATES

Patients with acne vulgaris, it has long been thought, are usually intolerant to carbohydrates. However, much recent evidence does not support such a view. Whereas earlier observations indicated that in many cases of acne borderline hyperglycemia is present, the majority of the more recent reports show that the sugar content of the blood of these patients does not differ significantly from that of normal subjects and that they show no evidence of a lack of tolerance to dextrose. In fact, the observation that the incidence of skin disorders was considerably less in a large series of diabetic patients than in a similar series of normal subjects led one investigator¹ to treat patients with furunculosis with a high carbohydrate diet and dextrose injected intravenously. The results obtained were uniformly favorable.

The foregoing alleged beneficial effect of carbohydrate therapy on furunculosis suggests that this regimen might prove of value also in the treatment of the more pronounced and pustular types of acne. A study of this question has been recently reported.² Ten patients who had been troubled with the severe and predominantly pustular form of acne for from six months to ten years were hospitalized and given a high carbohydrate diet, containing 5 Gm of carbohydrate, 1 Gm of protein and 1 Gm of fat per kilogram of body

weight. In addition, 1,000 cc of a 5 per cent solution of dextrose in physiologic solution of sodium chloride was administered intravenously each day. This treatment was continued for the two weeks the patients remained in the hospital and the high carbohydrate diet was continued after dismissal during follow-up periods varying from six to fourteen months. Dextrose tolerance tests were made on each patient at the beginning of the period of treatment and all curves obtained were normal with the exception of two, which were of the flat type. Sugar was not found in the urine at any time during the two weeks period of intensive carbohydrate therapy and at the end of the period the sugar content of the blood after fasting was normal in all cases.

These data obviously give no indication of an intolerance to carbohydrate. The clinical results are interesting. In five of the ten patients there was definite improvement during the two weeks period, and this continued during the follow-up period until the skin cleared. Two patients showed questionable improvement, and the condition of three remained unchanged. In no instance did a patient become worse as a result of treatment. Three of the patients showed transient outbreaks of acne during the follow-up period. In one instance this was associated with menstruation, and in another with the eating of tomatoes. Thus, further evidence is presented in support of the contention that patients with acne do not show an intolerance to carbohydrate and, indeed, that a carbohydrate-rich diet is frequently of value in the treatment of this disease. Possibly other types of foods, or perhaps specific foods may be involved as etiologic agents in acne rather than the long suspected carbohydrates.

INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON GENERAL'S OFFICE

Under date of May 4, 1936, Major Edgar Erskine Hume, librarian of the Army Medical Library, announced to the Surgeon General the completion of the first volume of the fourth series of the *Index Catalogue* of the Library. Volume 10 of the third series appeared in 1932, and publication has been suspended in the intervening time. The history of the publication is briefly reviewed in the introduction to the new volume of the new series. When it first appeared, the *Index Catalogue* was unique as the only attempt to index the important medical literature of the world. As the Army Medical Library received a greater number of periodicals and more books, pamphlets and other medical publications than any other medical library capable of issuing such a publication, the *Index Catalogue* most nearly approximated a complete catalogue of medical literature.

The *Index Medicus* was founded in 1879 and, as our readers know, was subsequently taken over by the American Medical Association and is now issued as

¹ Tauber E. B. Hyperglycemia in Diseases of the Skin. *Arch Dermat. & Syph.* 27: 198 (Feb.) 1933.
² Crawford G. M. and Swartz J. H. Acne and the Carbohydrates. *Arch Dermat. & Syph.* 33: 1035 (June) 1936.

the *Quarterly Cumulative Index Medicus*. To some extent there is duplication of the work necessary for preparing the *Quarterly Cumulative Index Medicus* and the *Index Catalogue*, though the claim is made that the *Index Catalogue* is far more comprehensive than the *Index Medicus*. Incidentally, the cost of issuing 1,000 copies of one volume of the *Index Catalogue* is estimated to be \$33,000, or \$33 per individual volume.

In presenting this new volume, certain changes have been made which are improvements in presentation of the material. For example, volume numbers are in Arabic numerals instead of Roman, unnecessary punctuation has been avoided, and there has been a shortening of inclusive pagination. The same classification is followed as has been used since the beginning of the first series, although of course new knowledge has made necessary new subheadings. Nomenclature has been improved by avoiding eponyms, although in some instances, as in Addison's disease, this has not been possible. It has been estimated that the changes are sufficient to save approximately one fifth of the available space. The Army Medical Library receives 1,509 periodicals, the *Quarterly Cumulative Index Medicus* receives some 1,400. Users of the two indexes will readily be able to determine for themselves which method of indexing has the greater facility. By its very nature the *Index Catalogue* is invariably far behind the *Quarterly Cumulative Index Medicus* in making available references to current medical periodical literature. However, the *Index Catalogue* makes available in one volume all the material up to the time of its publication.

Users of the *Index Catalogue* should be under no illusion as to the extent of material covered. It is not possible, and certainly not worth while, to attempt to index every article appearing in every one of the 1,509 periodicals received by the Army Medical Library, and it is quite obvious by reference to the *Index* that the editors have not attempted a complete indexing of this material. This is the system that has been followed by the *Index Catalogue* and the *Quarterly Cumulative Index Medicus* as well as by the *Index Medicus* from the first. The compilers of the *Index Catalogue* are to be congratulated on their editorial judgment.

Notwithstanding the minor criticisms here offered, the *Index Catalogue* is one of the most useful works of reference available in the field of medical bibliography. The economically minded may estimate that the completion of the alphabet in this manner will require anywhere from ten to twenty years and will cost approximately \$400,000. During the same period the *Quarterly Cumulative Index Medicus* will also be making available an index of the periodical literature of medicine at a cost of approximately \$40,000 a year. There will be considerable duplication of work which might in some way be avoided. It remains for medical leadership both governmental and extra-governmental to work out some plan whereby this may be done.

Current Comment

CAUSES OF SICKNESS AND DEATH

It is not as easy to determine the really important causes of sickness and death at present as appears on first glance. There are many approaches to the problem, but the relative importance attached to a particular disease depends largely on the source of information. Britten¹ has recently reviewed some of the angles of approach and indicated the various pictures that are yielded. Thus, in one table, in which the mortality rate for the whole United States in 1933 was listed only by primary causes, it was obvious that some of the causes, notably influenza and pneumonia, diarrhea and enteritis, and diseases of the heart, would have been increased if contributory causes also had been listed. As compared, however, with morbidity statistics, the mortality rates and their interpretation are relatively simple. Diseases that appear at the top of any list based on records of illness depend almost wholly on the method of collection. In a morbidity table based on reported incidence of those diseases which are by law notifiable in various states and are hence all communicable diseases, largely epidemic and principally of children, chronic disease is virtually omitted and many mild contagious cases are not included. In judging the importance of a disease it is necessary to consider the fatality as well as the incidence. When based on reports to the Public Health Service and the Cleveland study, rabies and tetanus head the list for numbers of deaths per hundred cases. Neither of these diseases is included in the table of the first seventeen important reportable diseases of 1933. Periodic canvasses (about every three months) were made for a year in 9,000 families in eighteen states. The four leading diseases, as based on annual incidence per thousand, were colds and bronchitis, influenza and pneumonia, tonsillitis and gastritis, as compared with measles, influenza, syphilis and scarlet fever in the group of important recorded diseases in 1933. Reports of sick benefit associations in industry give still another image, since such reports usually cover disabling illness lasting eight days or longer. In such a study influenza and pneumonia come first, followed by rheumatism, tonsillitis and appendicitis. The prevalence of diseases at any one time must be sharply distinguished from the incidence of illness. Thus, chronic conditions such as rheumatism and hernia may be important with respect to the ill health of the population but not show up in any great number in a study of cases of illness, because they are overshadowed by acute recurring conditions. Diseases that are increasing in frequency merit special attention. Data are not available, however, to cover this point except from the mortality rates, which are unsatisfactory because of changes in case fatality of specific diseases. None of the approaches to the problem seem to throw light on the important aspect of the protection of the worker against disease arising out of his occupation. When Britten attempted to bring the various approaches into a more or less unified whole, the tentative conclusion was drawn that the principal diseases appear to be (1)

¹ Britten, R. H. Important Causes of Sickness and Death. *J. Health Rep.* 51: 247 (July 17) 1936.

influenza and pneumonia, tuberculosis, heart disease, (2) cancer, rheumatism, dementia praecox, (3) syphilis, appendicitis, mental defect and results of childbirth. Since the importance of having accurate knowledge of the frequency and severity of different diseases is obvious, it is strongly to be hoped not only that accuracy and increase in the factual data will continue to improve but also that the statistical methods of reaching conclusions may be developed to give reasonably accurate information

Medical Economics

MUTUAL TRUST BETWEEN PHYSICIAN AND PATIENT IN MEDICINE

The patient who distrusts his physician will not and cannot tell him the whole truth and nothing but the truth. The patient who subconsciously doubts his physician may censor facts at the expense of his recovery. The physician who lacks the confidence of a patient will try to fill the gaps in his knowledge with guesses and laboratory gadgets or else take refuge in a "look and a bottle." This has happened whenever government, contracts or other arrangements in the distribution of medical service have disturbed or destroyed continuous, confidential, personal relations between patient and physician. In some systems of insurance and workmen's compensation, medical associations—usually after years of struggle—have restored some sort of freedom of choice and mutual confidence. The result has always been an improvement in the service. Is it necessary to introduce systems that destroy these essential features of good medical service?

The medical profession has always held to the principle that change in medical service must have the single objective of better care for the health of those who need such service. Physicians are not interested in arguments for change based on the profits that might accrue to financial and industrial interests, on political expediency or even on their own apparent financial advantage, if the service is to suffer thereby.

Through the experience of centuries in many different forms of society the medical profession has learned that certain elements are essential to good medical service. One of these elements is mutual confidence, which springs from the freely chosen association of physician and patient. Compulsory association sows distrust.

Patients, not diseases, are the objects of medical treatment. Treatment rests on a meeting of two personalities, the patient and his physician. Successful, helpful relations must be between these two personalities and not between an institution, insurance system, laboratory or industry and a personality.

The patient who suspects that interests hostile to him may be influencing the physician will consciously or unconsciously describe his symptoms with a view to meeting the supposed or real antagonism. Modern psychiatry confirms this conclusion and emphasizes its importance. Laboratory technic has not displaced the necessity of confidence in diagnosis, nor has elaborate equipment made it unnecessary in treatment.

Free choice is an essential element in furthering medical progress. It is the most effective method yet discovered to insure the "survival of the fittest" in the medical profession. The selection is not always perfect, but it is more fair and impartial than selection influenced by financial or political considerations. Coercion of the decision distorts and corrupts the verdict of professional success. Professional progress has always rested on high standards of admission and then on free competition, within the limits of approved ethical regulations.

The individual choice may not always be wise, but a compulsory choice hampers the success of the best physician, while a free choice helps him to give the best service of which he is capable. Potential power of choice tends to hold all medical service to a high plane.

Economic compulsion of choice has the same evil effects that have always followed advertising and solicitation by the physician. In practice compulsory choice is almost always accompanied by advertising and solicitation, and the choice is

often made by some impersonal corporation or institution that is concerned more with other interests than with the health of the patient. This impersonal body selects a physician not for an individual patient but for a group.

Group selection usually involves mass treatment. This policy is being urged on the medical profession just as analogous fields are rejecting it. A generation ago crime and insanity were treated almost exclusively by mass confinement in asylums and prisons, mass education was glorified and mass treatment of poverty by alms and in poorhouses generally approved. Progress in criminology, psychiatry, education and social work has been measured largely by the extent to which individual personal relations have supplanted mass measures.

Nowhere else is this personal relation such a fundamental element of successful treatment as in medicine. Progress toward better treatment, unless all the teachings of the past are false, will be found in the introduction of methods making the choice of physician more intelligent and the personal relations more permanent and confidential.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Society News—At a meeting of the Craighead-Poinsett County Medical Society in Trumann, July 22, speakers were Drs Isaac G. Duncan, on diagnosis and treatment of most common kidney infections, John A. Hughes, headache, Matthew W. Searight, gynecology, Edward G. Campbell, peptic ulcer, and John L. McGehee, pilonidal sinus, all are from Memphis.

CALIFORNIA

University News—The University of California recently announced a gift of \$2,000 from Mrs. Paul Wegefert, Coronado, for support of studies on the common cold.—In a student registration of 14,418 at the University of California, Berkeley, only three students died from natural causes during the academic year 1935-1936. The total student mortality was eight deaths. Of the entire student population, 11,997 were given some treatment in the Cowell Memorial Hospital.

FLORIDA

Committee Enlarged—The committee on maternal welfare of the Florida Medical Association has changed its name to the committee on maternal welfare and child health and added the following physicians as members: Drs. Luther W. Holloway, Jacksonville, William W. McKibben, Miami, Council C. Rudolph, St. Petersburg, and William E. Sinclair, Orlando.

GEORGIA

Increase in Venereal Disease—A total of 12,771 cases of venereal disease was reported to the state department of health in 1935, which is 2,161 more cases than reported for a group of other diseases including malaria, tuberculosis, whooping cough, diphtheria, typhoid and pellagra. For this group of diseases, a total of 10,610 was reported. The number of cases of syphilis was 7,358, while those of gonorrhea totaled 5,413. The rate for syphilis per hundred thousand of population was 242.8.

ILLINOIS

Maternal Welfare Program—The state department of public welfare has announced a plan to promote better hygienic care for prospective mothers and infants. Efforts will at first be concentrated in ten counties of the state showing the highest maternal and infant mortality rates and for which statistical material has been assembled for eight years: Richland, Pulaski, Alexander, Coles, Crawford, Montgomery, Morgan, Saline, Boone and Effingham.

Chicago

Professor Edwin O. Jordan Dies—Edwin O. Jordan, Ph.D., emeritus professor of bacteriology, University of Chicago, died at the Central Maine General Hospital, Lewiston,

Maine, September 2, from cerebral thrombosis, aged 70. Dr. Jordan was a native of Thomaston, Maine. He received his degree of bachelor of science from the Massachusetts Institute of Technology in 1888, his degree of doctor of philosophy from Clark University in 1892 and an honorary degree of doctor of science from the University of Cincinnati in 1920. From 1888 to 1890 Dr. Jordan was chief assistant biologist to the Massachusetts Board of Health, lecturer on biology, Massachusetts Institute of Technology, 1889-1890, fellow in morphology, Clark University, 1890-1892. In the latter year he became affiliated with the University of Chicago as associate in anatomy, holding successively the titles instructor, assistant professor of bacteriology, associate professor and professor. In 1914, when the department of hygiene and bacteriology was formed, Dr. Jordan was appointed chairman. Although officially retired from the university in 1933, Dr. Jordan had been offering graduate courses and conducting research in the department of hygiene and bacteriology. He was at one time chief of the serum division of the Memorial Institute for Infectious Diseases, now known as the John McCormick Institute of Infectious Diseases, of which he was a trustee, editor of the *Journal of Preventive Medicine* until its discontinuance in 1932, and joint editor of the *Journal of Infectious Diseases*. The Andrew McLeish Distinguished Professorship at the University of Chicago was awarded to him in 1932. He was president of the Society of American Bacteriologists in 1905, of the Chicago Pathological Society in 1906, of the American Epidemiological Society from 1929 to 1931, and of the Institute of Medicine of Chicago in 1932. Other societies of which he was a member include the American Public Health Association, American Association of Pathologists and Bacteriologists, American Physiological Society, Society of Experimental Biology, American Society of Naturalists, American School Hygiene Association and American Water Works Association. He was a member of the International Health Board of the Rockefeller Foundation from 1920 to 1926 and a member of the board of scientific directors, International Health Division of the Foundation. He was also a member of the medical fellowship board of the National Research Council and a fellow of the American Association for the Advancement of Science. He was elected a member of the Council on Foods of the American Medical Association in 1933 and of the National Academy of Sciences in the spring of 1936. He was awarded the Sedgwick Memorial Medal of the American Public Health Association in 1934. This medal was named for W. T. Sedgwick, a biography of whom was written jointly by Dr. Jordan, Dr. George H. Whipple and Charles-Edward A. Winslow, Dr. P. H. An outstanding bacteriologist, Dr. Jordan has contributed extensively to the literature of his field, one of his best known volumes being "General Bacteriology," which in 1931 underwent its tenth revision.

INDIANA

New Chairman of Department of Gynecology—Dr. Carl Habich, Indianapolis, has been appointed chairman of the department of gynecology at the Indiana University School of Medicine, and Dr. Jackson T. Witherspoon has been placed in charge of research in the department. A graduate of the school of medicine, Dr. Habich has been a member of the staff of the department of gynecology for about twenty years. Dr. Witherspoon was formerly instructor in clinical gynecology at Tulane University of Louisiana School of Medicine, New Orleans.

State Medical Meeting in South Bend—The Indiana State Medical Association will convene at the Jefferson Plaza, South Bend, October 6-8, for its annual session. Speakers will include the following:

Dr. Byrl R. Kirklm Rochester, Minn. Roentgenologic Features of Acute Pulmonary Diseases
Dr. Lincoln F. Sise Boston Present Day Anesthesia
Dr. Russell L. Cecil New York Early Diagnosis and Treatment of Pneumonia
Dr. Frederick A. Collier Ann Arbor Water Metabolism
Dr. Fred L. Adair Chicago The Cervix Uteri
Dr. Lee Wallace Dean St. Louis Nasal Sinus Disease of Infants and Young Children
Dr. Francis E. Senechal Chicago Early Diagnosis of Syphilis and Its Treatment
Dr. Elmer L. Seeringhaus Madison Wis., Endocrine Therapy in General Practice
Dr. John A. Toomey Cleveland A Critical Evaluation of Recent Advances in the Prophylaxis and Treatment of Contagious Diseases

The annual banquet Wednesday evening will be addressed by Dr. John H. Upham Columbus Ohio President-Elect American Medical Association on Changing Times in Medicine and Gordon J. Lang Ph.D., Chicago Are Doctors Human? A certificate of merit will be presented posthu-

mously to Dr. Walter J. Leach, New Albany, president of the state society in 1935. For entertainment, many side trips have been planned in addition to the annual golf and trap shooting tournaments. A dinner for women physicians will be held Monday evening, and Dr. Agnes Beulah Cushman, Chicago will speak on "Experiences in India." The annual smoker and stag party will be held the same evening, when the golf and trap shooting prizes will be awarded. The women's auxiliary will meet, October 6-7. Dr. Charles P. Emerson, Indianapolis as guest speaker, will discuss "What Can the Woman's Auxiliary Contribute to the Practice of Medicine?"

IOWA

Clinical Meetings—Drs. Dean D. Lewis and Walter E. Dandy, professor of surgery and adjunct professor of neurologic surgery, Johns Hopkins University School of Medicine, Baltimore, addressed a special meeting of the Des Moines Academy of Medicine and Polk County Medical Society September 4, on "Diagnosis of Bone Lesions" and "Diagnosis and Treatment of Brain Tumors" respectively. The guests conducted clinics in the afternoon. They conducted a similar program before the Linn County Medical Society, Cedar Rapids, September 3. At the regular meeting of the Des Moines group, September 26, Dr. Oliver J. Fay, Des Moines will speak on the subject "Would the Practice of Medicine as Envisaged Through the Social Security Act Contribute to the Security of Either the Public or the Medical Profession." Dr. William G. MacCallum, Baltimore, will address the Linn County Medical Society, October 2, on "Characteristics of the Hypophysis."

MAINE

Society News—Drs. Frederick C. Holden, New York, and David Riesman, Philadelphia, addressed the Hancock County Medical Society, Bar Harbor, July 24, on "Pelvic Infections in Women" and "Diagnosis and Treatment of Heart Failure" respectively. At a recent meeting of the Washington County Medical Association in Eastport, Dr. Frederick J. C. Smith, Eastport, among others, spoke on the diagnosis of acute appendicitis.

Medicolegal Society Formed—At a recent conference of medical examiners in Rangeley, a state medicolegal society was established with the following officers: Drs. Herbert C. Scribner, Bangor, president, John G. Towne, Waterville, vice president, George L. Pratt, Farmington, secretary, and William Holt, Portland, treasurer. Eligible for membership are the medical examiners, the attorney general of the state and his assistants and the county attorneys. Meetings are to be held at the time of the annual meeting of the Maine Medical Association.

MASSACHUSETTS

Health Cabin Dedicated—A cabin, erected at a cost of \$1,200 by the Worcester Exchange Club, was presented to officers of the Southern Worcester County Health Association in a formal dedicatory program August 12. The cabin is on the site of the Sterling Health Camp which through the season now cares for about 500 children. The children are divided into groups and stay at the camp four weeks each. About 3,000 children have been cared for at the health camp since its establishment in 1924.

MICHIGAN

Joint Meeting—The University of Michigan and the Children's Fund of Michigan held a conference at Marquette August 19-20. The session opened with a symposium on "What Constitutes a Complete Health Service for the Community," presented by Dr. Hugo A. Freund, Detroit, president of the fund, Dr. John Sundwall, Ann Arbor, Louise Knapp, R.N., Detroit, Howard B. Lewis, Ph.D., and Paul H. Jeserich, D.D.S., Ann Arbor. Other speakers included:

Dr. Henry J. Vandenberg, Grand Rapids Present Knowledge of the Cause and Cure of Cancer
Howard J. McClusky, Ph.D., Ann Arbor Growing Up Mentally
C. H. Jamieson, D.D.S., Detroit Some Aspects of a Full Denture Practice
George E. Morgan, D.D.S., Milwaukee Practical Pediatrics for the General Practitioner
Dr. Arthur C. Curtis, Ann Arbor Etiology and Management of Chronic Arthritis
Dr. Norman F. Miller, Ann Arbor The Obstetrics Problem

The program concluded with a discussion of community health services among others by Dr. Clyde C. Slemmon, Lansing state health commissioner and Miss Marjorie Delavan, director bureau of education state department of health Lansing.

MINNESOTA

Personal—Dr Hugh Cabot, Rochester, gave two lectures at St Thomas's Hospital, London, August 24-25, on "Treatment of the Obstructing Prostate" and "Cryptorchidism, with Particular Reference to the Effect of Malposition on the Testis and Methods of Treatment"—Dr Ralph M. Tovell, assistant professor in anesthesia at the University of Minnesota (Mayo Foundation), Rochester, has resigned to become chief anesthetist at the Hartford Hospital, Hartford, Conn., effective September 1—Dr Melvin S. Henderson, Rochester, has been appointed a corresponding member of the Argentine Society of Orthopedic Surgery.

Chiropractor Leaves State—Goes to Iowa—The Minnesota State Board of Medical Examiners, July 14, filed a complaint against A. A. Nitzke, charging him with practicing healing without a basic science certificate at Windom. Before the warrant could be served Nitzke left the state and, according to the board, is practicing chiropractic at Storm Lake, Iowa. Investigation disclosed that while he was neither registered under the basic science law in Minnesota nor licensed to practice chiropractic in the state, he was placed in charge of the chiropractic office of M. E. Tegels, who left on a trip to be gone about six weeks. Evidence was obtained to show that Nitzke gave chiropractic treatments to a number of Tegels' patients during the week of July 6. Any one learning that Nitzke is practicing in the state is urged to communicate with the state board.

MISSOURI

Director of Rural Health Named—Dr John W. Williams Jr., Springfield, health officer of Greene County for the past eleven years, has been appointed director of rural health with the state board of health under the social security program. Dr Lynn M. Garner, health officer of Miller County, has succeeded Dr Williams in Greene County.

Fall Clinical Conference—The Kansas City Southwest Clinical Society will hold its fourteenth annual fall clinical conference at the new Municipal Auditorium, Kansas City, October 4-8. Guest speakers will include

- Dr George E. Bennett, Baltimore. Treatment of Fractures of the Neck of the Femur. Recent, Old and Recurrent Dislocations of the Shoulder.
- Dr Milton A. Bridges, New York. Evaluation of the Under Par Man. Present Status of Nutrition in Relation to Disease. Fads and Fallacies Regarding Food and Diet.
- Dr Joseph A. Capps, Chicago. A Follow Up Study of a Series of Cases of Bacterial Endocarditis. Air Embolism versus Pleural Reflex as a Cause of Syncope in Operative Procedures in the Thorax.
- Dr George W. Crile, Cleveland. The Genesis and Surgical Treatment of Essential Hypertension. A Critical Review of 26,219 Operations on the Thyroid Gland with Special Reference to the End Results.
- Dr Morris Fishbein, Chicago. Heart Disease—How to Live Long in Spite of It.
- Dr Albert C. Furstenberg, Ann Arbor. Acute Infections of the Pharynx, Mouth and Neck. A Clinical and Pathological Study of Tumors and Cysts of the Head and Neck.
- Dr Urban Maes, New Orleans. Infections of the Dangerous Areas of the Face—Their Pathology and Treatment. The Justification for Exploratory Laparotomy in the Absence of a Definite Diagnosis.
- Dr Jay Arthur Myers, Minneapolis. Research Advances in the Diagnosis and Treatment of Tuberculosis. Modern Methods in Tuberculosis Control. Driving Tuberculosis from Our Midst.
- Dr Benjamin Weems Turner, Houston. Texas. Urethral Stricture in the Male and in the Female—History. Etiology and Treatment. Urology in Children.
- Dr Derrick T. Vail Jr., Cincinnati. Optochiasmatic Arachnoiditis. Its Relation to Sinus Disease and Multiple Sclerosis. Posterior Sclerotomy in the Treatment of Expulsive (Subchoroidal) Hemorrhage.

Scientific papers will also be presented by members of the society. New features this year include clinicopathologic conferences and special clinics on the heart, chest, gastro-intestinal tract, orthopedics, cancer and obstetrics and gynecology. Round table luncheons will be held each day, with addresses by two guest speakers. A public health meeting will be held Monday evening October 5. Tuesday evening the session will be presented in conjunction with the Jackson County Medical Society. Wednesday evening will be devoted to entertainment and the alumni dinner will be on Thursday evening.

MONTANA

Plague-Infected Ground Hog—Surg. Clifford R. Eskey, U. S. Public Health Service, in charge of plague suppressive measures. San Francisco, has reported plague infection in fleas and lice from ground hogs killed in Small Horn Canyon, about twelve miles southwest of Dillon, Beaverhead County. According to Dr Eskey's report, this is the first direct evidence that plague exists among marmots in America and demonstrates that the infection may be recovered from lice as well as from fleas taken from these rodents. Surgeon Eskey later reported that

plague had been identified in a sick ground hog. This hog, killed July 31 in Indian Creek Canyon, fourteen miles north-east of Beaver, Beaver County, Utah, is believed to be the first plague-infected marmot reported in the United States, according to *Public Health Reports*.

NEW YORK

Laboratory Head Honored—Dr Morris Maslon, Glens Falls, was honored at a testimonial dinner at the Fort William Henry Hotel, Lake George, August 5, celebrating his twenty-fifth anniversary as head of the Warren County Laboratory. Among the speakers were Drs Burke Diefendorf, Glens Falls, and Thomas Ordway, dean and professor of medicine, Albany Medical College. Dr Leonard H. Hulsebosch, Glens Falls, president of the Warren County Medical Society, and Miss Rose Q. Strait, superintendent, Glens Falls Hospital, arranged the dinner.

Personal—Harry Hamilton Laughlin, Sc D, assistant director of the Carnegie Institution, Cold Spring Harbor, received the honorary degree of doctor of medicine from the University of Heidelberg at the recent celebration of the five hundred and fiftieth anniversary of the university.

New York City

Tuberculosis Conference—The seventh clinical session on chronic pulmonary diseases held under the auspices of the Tuberculosis Sanatorium Conference of Metropolitan New York will be at Cornell University Medical College October 7. Dr Foster Murray, chairman of the clinical section of the conference, will preside, and a symposium on "Occurrence of Fluid in the Course of Artificial Pneumothorax" will be presented by Drs Hazel McLeod Riggins, Edgar Mayer, David Ulmar, John M. Nicklas, Valhalla, and William J. Ryan, Pomona.

NORTH CAROLINA

Graduate Assembly—The Medical Society of the State of North Carolina sponsored a graduate assembly at Banners Elk, August 20-21. The first day was devoted to a scientific program and the second to clinics conducted by Dr John H. Musser, professor of medicine, Tulane University of Louisiana School of Medicine, New Orleans. On the program were

- Dr Verne S. Caviness, Raleigh. Pneumonia.
- Dr Clyde M. Gilmore, Greensboro. Rheumatic Heart Disease.
- Dr Charles H. Cocke, Asheville. Evolution of Modern Treatment of Tuberculosis.
- Dr Duncan W. Holt, Greensboro. Backache.
- Dr William Allen Charlotte. Inheritance of Shaking Palsy.

Dr Musser made the principal address at a banquet at Pinnacle Inn Thursday evening. Dr Cocke was toastmaster. The clinics were held at Grace Hospital.

Changes at Wake Forest College—Dr Coy C. Carpenter, who has been acting dean at Wake Forest College of Medicine, Wake Forest, has been elected dean to succeed Dr Thurman D. Kitchin who was made president of the college in 1930. A new biochemistry laboratory has been equipped and the former space assigned for research, which is to be financed by a grant from G. Layton Grier, D.D.S., president of the L. D. Caulk Company, Milford, Del. Herbert C. Tidwell, Ph.D., recently in the department of biochemistry at Duke University, Durham, has been appointed Grier professor of biochemistry and will devote most of his time to research. A new laboratory for embryology and microscopic anatomy has been provided, the departments of gross and microscopic anatomy and those of pathology and bacteriology have been combined with added facilities and staff. Dr Edward S. King, professor of physiologic chemistry and bacteriology, is on leave of absence to spend the current semester at Harvard University Medical School, Boston, and Dr George C. Mackie, professor of physiology and pharmacology, at the University of Edinburgh.

OHIO

Hospital News—The Oxford Retreat, Oxford, a sanatorium for nervous and mental patients founded in 1882, was closed July 16 and its building leased to Miami University.—Dr Neal N. Wood, formerly director of Hillman Hospital, Birmingham, Ala., has been appointed director of Stirling-Loving University Hospital, Columbus.

Graduate Course in Ophthalmology—The Cleveland Ophthalmological Club announces that its annual graduate course in ophthalmology will be given December 7-9 and requests that those interested make early application for enrollment. The fee is \$15. Application should be made to Dr Albert D. Ruedemann, Cleveland Clinic, Cleveland, chairman of the program committee.

PENNSYLVANIA

Society News—Dr Bernard J Alpers, Philadelphia will address the Harrisburg Academy of Medicine, September 15, on "Common Nervous Complications Encountered in General Practice"—The Lehigh County Medical Society held its annual outing August 11 at the Lehigh Country Club

State Program for Crippled Children—With the aid of funds allotted by the Social Security Board, a plan for rehabilitation of crippled children has been launched by the state department of health. The state has been divided into twelve districts, in which a local orthopedic surgeon will have charge of the work. Children will be located, their disability diagnosed and recommendation made for treatment. Four clinics will be held in each district every year. Braces and appliances will be bought with social security funds and hospitals will be paid \$4 a day per patient for necessary services. The first clinic was held at Geisinger Hospital, Danville, August 20, under the direction of Dr Royal L Simon, Williamsport. Seventy children were examined.

SOUTH DAKOTA

Personal—Dr Clarence E Sherwood, Madison, has been appointed health officer of Lake County to succeed the late Dr Emerson W Goldman, it is reported—Dr Raymond P Frink, Wagner, has been appointed physician to the Yankton Sioux Indian reservation, succeeding Dr Gregory R. Waters

TEXAS

Society News—Drs Paul C Williams and Harold A O'Brien addressed the Dallas County Medical Society, September 10, on "Hypertrophic Arthritis" and "Tumors of the Testicle" respectively—Drs Walter R Russell, Purdon, and William C Tenery, Waxahachie, addressed the Navarro County Medical Society in Corsicana, August 1, on "Handicaps Overcome by a Country Doctor" and "Emergency Treatment of Burns" respectively

Division of Industrial Hygiene—The Texas State Department of Health has created a division of industrial hygiene financed by social security funds, with Dr Carl A. Nau, formerly professor of physiology at the University of Oklahoma School of Medicine, as director. Preliminary surveys are now in progress for location of potential health hazards in industry, which will be studied in detail in the laboratory now being equipped.

WEST VIRGINIA

Industrial Hygiene Unit Formed—A bureau of industrial hygiene has been established in the state department of health with Dr Otto J Swisher Jr, Berkeley Springs, as director. The bureau is financed by federal funds, under the provisions of the Social Security Act, matched by state appropriations. Among its first activities will be a survey of the silicosis hazard in the state. At a meeting of the state health commissioner with the advisory compensation committee of the West Virginia Medical Association it was agreed that x-ray plates made by the bureau in suspected cases would be used for no other than the survey purposes and that all persons suspected of having the disease would be advised to see their personal physicians.

Society News—Drs Russel Kessel and Andrew E. Amick, Charleston, addressed the Central West Virginia Medical Society in Webster Springs, July 25 on "Conservative Management of Pelvic Inflammatory Diseases" and "Practical Factors in the Management of the Acute Diarrheas in Infants and Children" respectively—The annual social outing of the Cabell County Medical Society was held at the Guyan Country Club Huntington, August 20 with a golf tournament followed by a dinner—Dr William B Scherr, Morgantown, addressed the Monongalia County Medical Society, August 4, on gynecologic subjects—The annual conference of health officers and meeting of the West Virginia Public Health Association will be held in Wheeling October 12-14

WISCONSIN

Personal—Dr Robert S Vivian has resigned as health officer of Beloit to devote his time to private practice—Dr John W Lowe Merrillan has been appointed health supervisor of the district including Ashland Bayfield Burnett Douglas Iron Sawyer and Washburn counties with headquarters at Ashland

Society News—The medical societies of Walworth, Kenosha and Racine counties held a joint meeting at Lake Geneva July 1, dedicated to Dr Benjamin J Bill, Genoa City, one of the oldest practicing physicians in the state. Speakers on the scientific program were Drs John C. Docter, Racine, on breast feeding, Francis D Murphy, Milwaukee, diagnosis and treatment of heart disease, Robert M Grier, Evanston, Ill., breech presentation, and Lathan A Crandall Jr, Chicago, practical aspects of liver function—Drs Lawrence V Liting and Lester McGary, Madison, addressed the Sauk County Medical Society, Baraboo, July 29, on "Skin Cancer and Its Treatment" and "Hay Fever and Asthma" respectively

PHILIPPINE ISLANDS

New Leprosariums Planned—A special committee of the bureau of health has selected sites for three regional treatment stations for lepers in Luzon Enrie, Cagayan, Bangued, Abra and Norzagaray, Bulacan. The president of the islands advocates establishment of these stations, according to the *Journal of the Philippine Islands Medical Association*, believing that it is unwise to segregate all lepers in Culion.

GENERAL

Study of Deaths from Excessive Heat—The North Central states had the highest death rate from excessive heat during the years 1931 to 1933, according to a study recently published by the Metropolitan Life Insurance Company in its *Statistical Bulletin*. Of nine groups of states, the East North Central states, including Ohio, Indiana, Illinois, Michigan and Wisconsin, and the West North Central group, including Minnesota, Iowa, Missouri, North and South Dakota, Nebraska and Kansas, had the highest group rates, each 2.2 per hundred thousand. Within these groups were the highest rates for individual states except Arizona and Nevada. They were Wisconsin 3.9, Iowa 3.2, and Illinois 3.1. The rate for Arizona was .97 and for Nevada .86. The rate for two groups of Southern states was .08 and for the Western Southern states of Oklahoma, Arkansas and Louisiana it was .09. When the rates for white and colored persons were separated, however, the rates for Negroes in the South were about twice as high as those for the white population.

Tuberculosis Meeting—The Mississippi Valley Conference on Tuberculosis and Mississippi Valley Sanatorium Association will convene at the Pere Marquette Hotel, Peoria, Ill., September 24-26. The preliminary program includes the following speakers:

Mr Murray A. Auerbach, Indianapolis, Training Workers in the Field of Practical Tuberculosis Activities.
Dr Hoyt E. P., "Evaluating Our Work in Terms of Improved Tuberculosis."
Dr David O., "Finding the Case: An Evaluation of Methods."
Mr Theodore J. Werle, Lansing, Mich., A Study of Tuberculosis in the Law.
Dr Amelia T. Wood, Muncie, Ind., What Should Our High Schools Teach About Health?
Dr Jay Arthur Myers, Minneapolis, Tuberculosis in a Health Teaching Program.
Miss Fannie B. Shaw, National Tuberculosis Association, The Objectives of School Health Education.
Dr Warren Wadsworth, Detroit, Bronchoscopic Observations of Tracheobronchial Obstructions in Tuberculosis.
Dr Sumner S. Cohen, Oak Terrace, Minn., and Kenneth A. Phelps, Minneapolis, Bronchiectasis Associated with Tuberculosis.
Dr Carl V. Weller, Ann Arbor, Mich., Pathologic Features of Bronchogenic Carcinoma.

There will be a symposium on nontuberculous pulmonary lesions Thursday afternoon with the following speakers: Drs. Ferris Smith, Grand Rapids; Jacob J. Singer, St. Louis; Cameron Haight, Ann Arbor, and Oscar A. Sander, Milwaukee. A joint session of the sanatorium association and the tuberculosis conference will be held Friday morning. Speakers will be Dr Arthur A. Pleyte and Metta Bean Milwaukee on "Opportunities for Finding Tuberculosis in Relief Families"; Dr Robinson Bosworth, Rockford, Ill., "The Role of the Sanatorium in the Control Program"; Dr Myers, Minneapolis, "Latent Period Between Infection and So-Called Adult Disease as Occurring in Childhood up to Adolescence," and Dr Allen K. Krause, Tucson, Ariz., "Pulmonary Tuberculosis in Childhood." An x-ray clinic will be conducted Friday evening by Drs Henry Kennon Dunham and Vera V. Norton Cincinnati.

Academy of Ophthalmology and Otolaryngology—The forty-first annual convention of the American Academy of Ophthalmology and Otolaryngology will be held at the Waldorf Astoria Hotel, New York, September 26 to October 3 under the presidency of Dr Frank E. Burch, St. Paul. Sir John Herbert Parsons, London, the guest of honor will speak at the opening joint session Monday morning on Ophthalmology.

and Research." At this session Dr Burch will give the presidential address, and a symposium will be presented on "Manifestations of Diseases Affecting Cerebral Nerves Supplying Eye, Ear, Nose and Throat Due to Involvement of the Central Nervous System" by Drs Donald J Lyle, Cincinnati Marvin F Jones and Henry A Riley, New York. The succeeding mornings will be devoted to conferences and the afternoons to addresses by the following speakers, among others

- Dr Lee W Dean St Louis, Fundamental Principles in the Treatment of Allergic Rhinitis with Special Reference to Iontophoresis (Ionization)
- Dr Robert H Ivy Philadelphia Tumors and Cysts of the Mouth and Jaws of Interest to Otolaryngologists
- Dr Alan C Woods Baltimore Allergy in Clinical Ophthalmology
- Dr Samuel Hanford McKee Montreal, Canada Sarcoma of the Uveal Tract—Malignant Melanoma
- Dr Arthur J Bedell Albany N Y Pigmentation of the Fundus
- Dr John J Shea Memphis, Tenn Indications for Blood Transfusion in Otolaryngologic Work
- Dr Joel J Pressman Los Angeles A New Method of Radium Application in Cancer of the Bronchus
- Dr Parker Heath, Detroit Visual Sequelae from Meningococcus Meningitis
- Dr Karl L Stoll Cincinnati Glaucoma and Nevus Flammeus

The section on instruction is sponsoring a special symposium Tuesday evening on "Lymphatic Drainage of the Head," presented by Dr Oscar V Batson Philadelphia, Dr Augustus G Pohlman, Omaha, and Olof Larzell, Ph D, Portland, Ore. The committee on deafness prevention and amelioration will present a symposium Tuesday afternoon on progress in this field, with the following speakers. Drs Horace Newhart, Minneapolis, Austin A Hayden, Chicago Burt R Shurly, Detroit, and Miss Betty C Wright, executive director American Society for the Hard of Hearing, Washington, D C. Monday evening there will be a dinner meeting at which a panel discussion on graduate medical education will be presented. Dr Willard C Rappave, dean Columbia University College of Physicians and Surgeons, will introduce the discussion, and participants will be Drs Ralph A Fenton Portland, Ore Dean M Lierle, Iowa City, Harris P Mosher, Boston, Cecil S O'Brien, Iowa City Harry S Gradle, Chicago, Walter B Lancaster, Boston, and William D Cutter secretary, Council on Medical Education and Hospitals, American Medical Association, Chicago. For the first time the academy will have a scientific exhibit. Friday and Saturday will be given over to clinics at various hospitals, with a dinner at the New York Academy of Medicine Friday evening for those participating.

Deaths in Other Countries

Lord Moynihan of Leeds, emeritus professor of surgery, University of Leeds and chairman of the Army Medical Advisory Board, died in Leeds, September 7, aged 70.

Government Services

Closing Date for Applications Changed

The U S Civil Service Commission announces that the closing date for receiving applications for examinations for medical officers announced in THE JOURNAL August 29 has been changed from September 8 to September 15.

Forty-First State Free from Bovine Tuberculosis

Rhode Island is the forty-first state to be designated a modified accredited area, practically free from bovine tuberculosis. The term modified accredited area means that there is less than one half of 1 per cent of tuberculosis among cattle as shown by official testing. Tuberculosis eradication was undertaken in Rhode Island about twenty years ago and has been greatly increased in the last five years.

Medicomilitary Inactive Training

The eighth annual training course for medical department reservists of the U S Army and Navy will be held at the Mayo Foundation, Rochester, Minn, October 4-17. Morning hours will be devoted to professional work in special clinics and study groups, while the afternoons and evenings will be given over to a medicomilitary program under the direction of the surgeon of the seventh corps area and the surgeon of the ninth naval district. Enrollment, limited to 200, is open to all army and navy reservists of the medical departments in good standing. Applications should be submitted to the surgeon of the seventh corps area, Omaha, Neb, or the surgeon ninth naval district Great Lakes, Ill.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 25, 1936

The Annual Meeting of the British Medical Association

The 104th annual meeting of the British Medical Association was held at Oxford. At the representative meeting a discussion took place on the important subject of the space occupied in the *British Medical Journal* by the publication in extenso of the proceedings of the scientific sections at the annual meeting. It was moved (1) that it be left to the discretion of the editor as to how fully they be published and (2) that in consequence of the curtailment thus entailed a special edition of the *Journal* be devoted to papers of the sections. From the last annual meeting these ran to 244 pages of the *Journal* over a period of twenty-five weeks. While allowed discretion as to the occasional papers, the editor must publish the opening papers of every section. This year there were twenty sections with thirty-eight meetings. The papers to be published might run to 190,000 words or more. There was an objection to the bulkiness of the material and also to the fact that some of it might be out of date at the time of publication.

Dr R G Gordon, chairman of the *Journal Committee*, said that this matter had exercised the committee. A great proportion of the *Journal* was occupied by these papers, which were of unequal value. No one would like to go back to the publication of all the papers read at the annual meeting, which had been abandoned. The opening papers were now published and the committee had decided that in future the authors would be asked to cut them down to 3,000 words, leaving it to the discretion of the editor to allow a little excess should the paper so demand. The separate publication of the proceedings of the annual meeting would be expensive, running to \$7,500. This was done at the London clinical meeting of 1919. It was thought that the contributions—the result of four years of war—would be of special interest, but the sales were negligible. There were difficulties in the proposal that the opening papers should be submitted to the editor like other articles. Unless the opener was assured of publication, he might not take the trouble to prepare his paper. Also extreme pressure on the editorial staff would be involved. The first part of the resolution was carried and the second part lost by a large majority.

In his report on *Journal* policy, Dr Gordon stated that 1,008 original articles were received last year and 544 published. The latter had to be closely edited. The editorial department received 12,972 letters and sent out 8,722. Books received for review amounted to 908, of which 595 were reviewed, a large proportion, in view of the average value of the books now published. It has been decided to adopt a new typography and a new type face for the *Journal* and to contract with a printing firm for the whole production instead of doing the composition and setting in the Association's House, as at present.

ANNOUNCEMENTS IN NEWSPAPERS

The following recommendation of the council was moved: "That in the opinion of the association the lay press should never be utilized by a practitioner to publish his change of address, to announce his movements, or to announce his surgery (office) or consulting hours. There is no objection to such matters being issued by a circular letter to patients of the practice. Such circulars should be issued in sealed envelopes and be confined to those whose names have been on the books of the practice during the last two years and who are not

known to have transferred themselves to another practitioner" The recommendation, amended by omitting the word "sealed" and substituting "are on the books of the practice" for "have been during the last two years," was carried

THE FUTURE OF MEDICINE HEALTH CENTERS

In his presidential address Sir Farquhar Buzzard, regius professor of medicine in the University of Oxford, said that the day had passed when any doctor, whether in general or consulting practice, could legitimately carry on as an isolated and independent unit ready to meet all the requirements of his patients. He must be part of a team. Modern means of communication made possible the establishment of health centers where the personnel and equipment necessary for skilled diagnosis and treatment can serve large areas. Every physician in the area should belong to the service and be part of the team, of which each member had his own specific functions. For two reasons general practitioners should become more intimately associated with such health centers. The voluntary hospitals were understaffed and therefore the standard of efficiency was not as high as it would be if general practitioners participated in the work. In the second place they would benefit if they could devote even two or three hours a week to hospital work, thus keeping in touch with colleagues and abreast of contemporary advances. Sir Farquhar envisaged a central board, based on the chief hospital, but representative of all interests and institutions concerned with the health of the district. Where a medical school was included it would send delegates of the more academic departments. The board would coordinate all the preservative, preventive and curative services within the district.

The whole system of voluntary hospitals was threatened by the establishment of municipal hospitals all over the country, which in the future would be equally well equipped and afford the same opportunities for clinical study and, unlike the former, would pay for full time or part time study. Thus, with the increasing demand of well-to-do patients for treatment in hospitals, must lead to the disappearance of the purely honorary position of the staff in voluntary hospitals to some system of payment for their part time services.

General practice was disturbed and still threatened by recent changes. Insidiously but steadily it had been lopped of many of its branches. This was partly in response to the demand of the public, for economic or other reasons that various services, not limited to the field of public health, should be controlled by local authorities. But he failed to see why general practice should not assume a more important role in the future. The saving of life had become the job of institutional team work, the saving of health and the prevention of illness, in the long run more important, must be initiated by the general practitioner in the home. But to perform this work efficiently he must help to staff those medical services, preventive and curative which have been diverted to the control of public health authorities.

TREATMENT OF FRACTURE OF NECK OF FEMUR

Opening a discussion in the Section of Surgery, Royal Whitman stated that fracture of the neck of the femur was amenable to the rules that govern the treatment of other fractures. By the abduction method deformity could be corrected and displaced fragments apposed with ease and certainty. In former years the proportion of union obtained in complete medial fractures was very low. 6 per cent in one series, 11.6 in another. The lowest percentage of union reported for the abduction method was over 53. Henderson of the Mayo Clinic estimated the prospect of repair at 90 per cent in patients under 60 and at 65 per cent beyond that age.

Smith-Petersen based his spiking operation on the capacity for repair demonstrated by the abduction method. To reduce the percentage of failure he exposed the fractured surfaces, adjusted by direct manipulation and fixed his flanged nail. In his first series of twenty-four cases union was attained in 75 per cent, in a second series of twenty six, in 70 per cent. Several deaths occurred, but not directly from the operation. The experiences of others had been less fortunate. Another operation was apposition of the fragments by the abduction method and fixing them by the Smith-Petersen nail. Whitman suggested that the insertion of the nail impaired the capacity for repair by injuring the cancellous tissue. The early resumption of activity claimed was a doubtful advantage. The fragile cortex of elderly patients might give way.

THE NEW SECTION OF NUTRITION

Sir Robert McCarrison opened a discussion at the new Section of Nutrition, which was inaugurated at this meeting, on "Nutrition in Health and Disease." He said that last among the sections it was not the least and the day was not far distant when, instead of one morning being devoted to its work, it would rank with the Section of Medicine as a three-day fixture. It was becoming apparent that the science of nutrition was the foundation of a more rational medicine. He hoped that in the future the work of the section would not be limited to physiologic, biochemical, pathologic and medical aspects of the subject but would include veterinary and agricultural topics. The foods now called "protective" were discovered centuries ago by certain races of northern India whose physique and health were unsurpassed. Such foods must be produced on soils that were not depleted of essential plant nutrients, such as iodine, which was needed for the normal nutrition of man. Poverty was not the only cause of malnutrition. Education of the people and better education of ourselves were urgent necessities. It might be said that the medical curriculum was already overloaded. If so, let it be pruned, let us teach the student less about disease and drugs and more about health, more about nutrition, which is the very basis of health.

THE POLLUTION OF SHELLFISH

In the Section of Public Health Dr. R. W. Dogson, director of shellfish services, Ministry of Agriculture, said that had we set out to ensure the continued existence of typhoid in this country we could have hardly found a better plan than that of turning out the crude sewage from the large centers of population on to a shellfish bed and then distributing the shellfish all over the country. Success might be doubly assured by importing, as we did, shellfish from countries in which the incidence of typhoid was much greater than our own. The disposal of sewage by discharge into the sea was described as "purification by dilution." In the presence of shellfish it might be described as "purification by concentration." An oyster could filter out and retain for a considerable period all the suspended matter from at least 10 gallons of water in the twenty-four hours. Attempts to grapple with the situation had been ineffective. The deviation of sewers was impracticable owing to its cost. So was the purification of sewage. Closure of polluted fisheries had been done on a considerable scale. Two thirds of the mussel beds in England and Wales had been closed. The only practicable form of purification was one that was carried out under artificial conditions in tanks. The alternative was that all molluscan shellfish would have to be banned.

THE USE AND ABUSE OF MANIPULATIVE SURGERY

In the Section of Orthopedics Mr. Blundell Bankart said that the great majority of civilized people had acquired restriction of the natural mobility of their feet, so that it

could not flatten without meeting with resistance of the soft parts, producing pain. But the completely flat foot was painless. The medical profession and the public were obsessed with supporting the arch of the foot. In theory this was ridiculous, for the foot was meant to be an active supple member not rigid like a block of wood, and in practice this had proved a failure. On the other hand the bonesetter smashed the arch of the foot, or, to put it less crudely, he restored its mobility, so that it could flatten without resistance and therefore without pain, and he cured his patients. Foot strain (not flat foot) was one of the commonest ailments and might be postural or traumatic in origin. It could be cured by manipulation and in no other way.

As for the other side of the picture, a physician brought his son with an obviously tuberculous elbow. He had taken him to a bone setter, who had violently manipulated the joint and it had flared. As the bone setter had no medical training it might be said that he never should manipulate a joint. But what about flat foot and other cases cured by bone setters after failure to get relief elsewhere? Mr. Bankart still heard of orthopedic surgeons of repute who treated so-called flat foot with arch supports, who did not recognize sacro iliac strain, the commonest cause of pain in the back, and who professed to be familiar with manipulative surgery but seldom practiced it. To dispense with bone setters, surgeons should be willing to undertake all the manipulative work that was previously done by these.

Osteopathy Mr. Bankart described as an American stunt based on the unsupported assertion that almost all diseases are caused by imaginary displacements of the spine. It had been investigated up to the hilt and found wanting. It was up to all orthopedic surgeons to see that these confidence tricks were exposed and to ensure that manipulative surgery was practiced and taught in all medical schools.

EXHIBITION OF MEDICAL BOOKS AND MANUSCRIPTS

The famous Bodleian library arranged an interesting exhibition of medical books and manuscripts, such as would be possible nowhere else. The earliest manuscript was an English missal of A. D. 970 containing a magical device for discovering whether a sick man will live or die, a matter in those days important to the clergy in the administration of extreme unction. There was a manuscript written about 1290, giving the first known representation of dissection, an English herbal of about 1100 in which many of the plants were drawn from living specimens, and another of somewhat later date in which is depicted a mad dog and a bitten man in a hydrophobic seizure. But the exhibition was chiefly concerned with the study of medicine at Oxford, and especially with the famous group of Oxford men who adorned the medical profession in the seventeenth century. The statutes of the Faculty of Medicine, written before 1350, were shown. There were manuscripts of some of the medical authors studied at Oxford in the Middle Ages—Hippocrates, Galen, Isaac Judaeus and Nicolaus Praepositus. The earliest record of a medical degree is in the Register of Congregation, where it is recorded that Thomas Edmonds was allowed to proceed to the degree of D.M. in 1450. There was also a manuscript of the "Rosa Anglica" by John of Gaddesden (who died in 1361), the earliest account of phototherapy. He treated a son of Edward I. of smallpox by wrapping him in scarlet cloth. The greatest name in Oxford medical history of the sixteenth century is that of Thomas Linacre, founder of readerships in both Oxford and Cambridge. His translation of Galen's "De Temperamentis" on vellum was shown. The books of the seventeenth century began with Harvey's "De Motu Cordis" (1628), in which he first published his discovery of the circulation of the blood.

Two-Stage Lobectomy

The advantages and disadvantages of two-stage lobectomy was the subject of a paper read by Robert Monod at the May 15 meeting of the Société de chirurgie of Paris. In a paper read at the July 14, 1934, meeting Monod had defended the principle of a one-stage lobectomy, when no pleural adhesions exist, for bronchopulmonary suppuration. At that time, however, he called attention to the fact that such a one-stage operation is always undertaken with some degree of anxiety as to the result. A lobectomy, when no pleural adhesions exist, can be followed by immediate cardiopulmonary accidents as well as certain later ones, such as extension of infection to the mediastinum, to other lobes or to the pleural cavity. To avoid such complications, the most important measures employed at present are baronarcosis, bronchorespiration and irreversible drainage. In spite of these additions to the technic, two potential dangers must be faced: (a) cardiopulmonary accidents during the operation and (b) extension of infection to the pleura after operation. The patient is often a poor operative risk because of his bad cardiac condition and because of the long standing infection. An empyema is especially to be feared owing to the fact that the lobectomy stump may open and allow pus to escape into the pleural cavity, giving rise to a very virulent and rapidly spreading infection.

The two-stage operation has certain advantages according to Monod. The first stage is one of preparation of the pleura: i.e. adhesion of the noninvolved lobe (left) or lobes (right) to the parietal pleura. Another advantage of the two stage operation is that it places less of a burden on the heart. Finally, liberation of the involved lobe during the first stage enables it to discharge much of its purulent contents through its main bronchus. The disadvantages of the two stage operation are that the risks due to the anesthesia are twice as great as in the one-stage operation, one is less able to take care of the pedicle following the lobectomy, fistula formation occurs more frequently, and removal of the lobe itself is more difficult. A two-stage lobectomy ought to be performed when no pleural adhesions are present, as follows. During the first stage the involved lobe is mobilized with or without preparation of the pleura to aid the noninvolved lobe or lobes to become adherent to the chest wall, while during the second stage, after immediate lobectomy and care of the pedicle, the chest wall is hermetically closed followed by irreversible drainage.

In younger patients with a normal heart, with little infection or fever, without expectoration, and with only slight adhesions, the one-stage operation is indicated, but in patients with fever, evidences of toxemia and a doubtful cardiac condition, a two stage operation is safer. Monod reported a case of lobectomy for bronchiectasis of the left lower lobe in a boy 18 years of age, in which a two-stage operation had been followed by an excellent result.

In the discussion, Maurer stated that the question of infection of the pleural cavity was the most important one. When there is little secretion, lobectomy for bronchiectasis is successful in from 80 to 90 per cent of the cases.

Sequelae of Acute Respiratory Disorders

The Société d'hydrologie et de climatologie médicale de Paris chose the subject of sequelae of acute disorders of the respiratory viscera for discussion at its March 16 meeting.

The first paper was by Professor Rist, who stated that a certain number of acute disorders of the respiratory organs, although apparently cured can be followed by cicatricial lesions giving rise to functional disturbances in some patients, or at least such lesions constitute areas of diminished resistance which

favor some other pathologic condition. As examples of sequelae of a healed pneumonia, Rist cited interlobar adhesions and of a pneumococcal (diffuse) pleural exudate, obliteration of the free pleural space, i. e., adhesions between the costal and visceral pleurae. Such sequelae complicate greatly the artificial pneumothorax treatment, if a pulmonary tuberculosis develops later. It is of no importance when one is confronted later with these sequelae whether the primary infection is pneumococcal or streptococcal, because it bears no relation to the obliterating adhesions. The same held true for bronchiectases. The original causative organism has disappeared at the period when the sequelae are encountered clinically. Attention was directed to the mistakes in diagnosis, especially from the roentgenologic point of view. A thickened pleura, although it offers resistance to the needle employed for an exploration, does not yield an abnormal shadow on the film. No pathognomonic sign of an obliteration of the pleural cavity exists. All one knows is that the establishment of an artificial pneumothorax is impossible, even though the needle is introduced at a number of places on the chest wall. A sclerosis of the pulmonary parenchyma following an acute frank pneumonia is always very complex, both in adults and in children. It is accompanied by an emphysema the characteristics of which both as to etiology and to tissue changes are quite distinct from those of the sclerosis. The use of the latter term has been greatly abused, especially as applied to sclerosis of the apexes and to that accompanying an emphysema. At present there is a tendency to ascribe all sorts of roentgenographic changes to sclerosis which really bear no relation to it. Bands, foci and thickenings of the parenchyma are all ascribed to sclerosis. The latter is of no clinical importance unless complicated by bronchiectasis. The latter never exists in the sense of the classic interpretation of the term unless there is an accompanying infection of the epithelial lining and wall of the bronchi as well as of the adjacent pulmonary parenchyma.

From the period at which the lesions of the primary pneumopathy, instead of disappearing by resolution, persist and sclerosis results, the infection establishes itself in the contiguous areas. The infection persists and often is latent. The physiologic mechanisms that are responsible for the spontaneous disinfection of the previously normal respiratory tract do not function in a portion of the parenchyma the structure of which is seriously altered. The various acute pneumopathies are the principal factor in the etiology of bronchiectasis, other factors such as tuberculosis, hereditary syphilis and recurrent rhinobronchitis being of only limited etiologic importance. Even if there exists a congenital predisposition to bronchiectasis, one cannot deny the necessity of a sclerogenous infection in transforming such a predisposition into a real bronchiectasis.

Rist emphasized the value of bronchography with iodized oil as a diagnostic and prognostic measure. The treatment of choice for bronchiectasis is artificial pneumothorax for the early cases and lobectomy for those in which such a method of treatment is not successful.

In the discussion Sergeant expressed the belief that there are many different causes of a bronchiectasis. Some are of congenital origin, but these constitute the minority. The non-congenital type can follow an acute bronchopneumonia and persist for a long time, or it can develop on the basis of a bronchopulmonary sclerosis and have as a sequel marked dilations which are not improved either by phrenicectomy or by collapsotherapy.

Lereboullet stated that in a large number of cases of bronchiectasis in children the initial role of bronchopneumonias was not very apparent and that they seemed to act as a factor aggravating already existent lesions. Phrenicectomy had been successful in some cases. This was equally true of placing the children in bed with the head lower than the feet. In children the prognosis of bronchiectasis is relatively favorable.

Leon-Kindberg thought that, although a congenital origin of bronchiectasis could not be denied, such a cause was very rare. Collapsotherapy was of little value in case of infection. In fact, disastrous results might follow its use.

July 16, 1936

The Society for Research on the Circulation

The Society for Research on the Circulation recently convened jointly with the Medical Committee of the German Society for Industrial Protection. Professor Reiter, president of the National Health Bureau, acted as chairman of the joint meeting. The common topic of discussion proposed was 'Circulatory Disorders from the Standpoint of Social and Industrial Hygiene.'

W. Weitz of Hamburg spoke first on the hereditability of circulatory diseases. When this type of defect appears among members of one family it is more frequently to be encountered in a group of siblings or in a collateral branch and less likely to appear as a directly inherited trait. Heart disease probably follows the dominant as well as the recessive hereditary transmission. The high familial incidence of inherited cardiac defects, as has been verified by observation, depends in particular on hereditary predisposition to angina and articular rheumatism, wherein a special susceptibility of the cardiac valves may also play a part. Manifestly inherited, as research on twins and families has established, are those constitutional cardiac disorders which frequently accompany infantilism, asthenia, endocrine dysfunction, unstable sympathetic nervous conditions, excessive susceptibility to fatigue, and nervous and psychopathic disturbances. In many such cases a dominant hereditary transmission could be detected. Dominant heritability is an important etiologic factor in high arterial pressure. External influences such as might be exerted by alcohol, nicotine, psychic excitement and hard physical labor probably serve to make manifest a disease already present in a latent form.

S. Koller of Bad Nauheim demonstrated with statistics that circulatory diseases have become shockingly important in recent years. Group examinations show a circulatory disturbance present in every thirteenth person, and circulatory disease is responsible for every fourth fatality. Aortic sclerosis is found in the middle decades of life in nearly every one. Certain it is that the aging of the population and the improvement in diagnostic accuracy have increased the incidence of circulatory disease as represented statistically. Whether, in addition, an actual increase has taken place cannot be stated with certitude. In medical statistics a frequently unavoidable bias may influence both the individual observation and the compiled material, and this constitutes a source of error.

A further report was submitted by Koelsch, occupational hygienist, of Munich, on 'Circulatory Impairment by Occupational Intoxication.' The usual occupational intoxications are caused by partial impairment of the cardiac muscle and of the vascular system, some encroach on the nutrition of the cardiac muscle as toxins of the blood, others affect the autonomic nervous system. Irritant gases can lead, by means of vagus shock, to complete arrest of cardiac action. An endocarditis produced by inhalation of poisonous gas must be considered out of the question. A specific cardiac reaction to lead poisoning is not recognizable, although impairments of the heart muscle were observed in forced animal experiments. Acute saturnism in man is accompanied by many dyspneic manifestations which are perhaps due to spasms in the coronary vessels. Severe cardiac disturbances in chronic lead poisoning are to be regarded as secondary phenomena. Functional disturbances of cardiac action may be due to the effect on the vagus and the sympathetic combined with endocrine dysfunction. Nicotine assumes a pathologic occupational role in the tobacco industry.

New workers have been known to suffer attacks of cardiac palpitation, tachycardia, increased blood pressure and so on

Hanns Lohr of Kiel then spoke on "Mechanical Impairment of the Circulation" In the most severe contusions of the thorax, external lesions are not necessarily present, although the heart itself may suffer the most serious damage Lacerations of the valves and tendinous fibers are seldom found in completely healthy hearts In "commotio cordis" one finds with regularity pronounced, characteristic changes in the electrocardiogram, posttraumatic decline in the arterial blood pressure, and acute dilatation of the heart Disturbances in cardiac rhythm are entirely independent of the vagus It is essential to correct diagnosis of the commotional manifestations that all cardiac symptoms should appear immediately after the accident, for heart and vascular disorders that appear later on may also be elicited by the cerebral system

Hermann Schriddle of Dortmund discussed the effect of electrical trauma on the circulatory system Animal experimentation is to be interpreted with the utmost caution, since man is capable of reactions to the electric current quite unlike the reactions of animals In cases of burns caused by an electric arc with its heat of about 3,000 C., complete necrosis in the walls of the blood vessels in the burned area is to be observed Impairment from an electric current produces a contraction of the blood vessels, the severity of which is in proportion to the current's strength Symptoms of cardiac dysfunction in such cases are due to blood perfusion disturbances in the coronary vessels, which lead at length to heart failure In 48 per cent of fatalities from electric currents, arrest of respiration is the cause of death, the cardiac death observed in 52 per cent is not in every case related to ventricular fibrillation Although alternating and direct currents exercise a similar effect on both respiration and circulation, the alternating current is from three to four times more powerful than the direct current In case of electrical trauma it is therefore necessary that any attempted resuscitation be directed to the circulatory as well as to the respiratory apparatus Despite years of research, no explanation of the exact cause of death in these cases has been forthcoming But one thing is certain impairment caused by electricity will chiefly involve the circulatory system

T Fürst of Munich has made a study of the circulation of young male workers with regard to occupational selection He was therefore able to furnish his audience an insight into the postwar biologic changes in the constitution of the average youth of trade apprenticeship age Chronologically, the first phase of the change, chiefly characterized by impaired nutrition, coincides with the period directly following the war In the second period, external constitutional impairments became particularly numerous The third phase (covering the period from 1930 to 1936) was marked by an increase in functional disturbances of the circulatory and nervous systems The number of these functional anomalies of the circulation is nearly double what it was in prewar years

As A Weber of Bad Nauheim pointed out, the great increase in fatal cases of circulatory disease, observed in all civilized countries, must be ascribed to a certain wear and tear on the organism Heredity is a prominent pathogenic factor in hypertension but coronary sclerosis may be traced to the most disparate environmental factors as well By suitable adaptation of living habits the progress of hypertension may be retarded, but it is questionable whether a hypertension once established can be reduced again to its latent stage The hypertonic patient will ultimately die of renal insufficiency, apoplexy or progressive cardiac insufficiency unless death should take place earlier from an intercurrent illness The cardiac insufficiency manifests itself gradually If this condition receives timely treatment working capacity and the life span can be prolonged for many years

The Third International Congress on Air Service in Medical Emergencies

The medical air service association (l'Aviation sanitaire) met at Brussels to examine a series of problems relating to the organization of medical emergency air service in the colonies and to the cooperation of private and public agencies in the event of a disaster

The third International Congress on Air Service in Medical Emergencies approved the recommendations of the International Committee for Research (which reflect the opinion of all students of the subject) with regard to the coordination of effort and the establishment of permanent collaboration between aeronautic and sanitary organizations

The congress went on record as desirous that collaboration be established among all countries and that favorable progress in this direction be brought to the attention of the various national committees on emergency aviation by the International Committee of Research

To hasten assistance in emergency cases in regions lacking transport facilities the congress recommended that international agreements guarantee a practical system of liaison between aircraft and the ground, also that arrangements be made to assure persons carried in aircraft the necessary medical attention both aloft and on the ground To this end special instruction should be given the staffs of all aircraft and a permanently organized ground first aid service should be instituted at all flying fields The third congress reiterates the recommendation of the first congress that any aircraft actually engaged in medical emergency flight should be subjected to a minimum of red tape incident to international travel (customs examinations, taxes and so on) and should be accorded priority in landing The congress further recommends that special removable international insignia be adopted for the exclusive use of aircraft actually engaged in the fulfillment of an errand of mercy yet not qualified to display the insignia of the Red Cross

Problems to be discussed by the fourth congress are (1) instruction in the utilization of aircraft in medical emergencies in the colonies, (2) safety aboard aircraft on medical missions, (3) respective duties of the aeronautic and of the medical personnel in event of evacuation by aircraft

The Injurious Effects of Heliogravure

Dr Glibert's monograph recently appearing in the *Bruxelles medical* warns against a variety of occupational poisonings, including serious intoxications that occur among the employees of printing establishments engaged in the relatively new process of heliogravure The noxious substances involved are hydrocarbons of the aromatic series that bear collectively the proprietary name of "Xylois" The most visible sign of trouble manifested by the employee is a slightly olivaceous pallor The symptoms, during the static stage of the intoxication, are caused by the strong destructive action of the noxious substance on the patients' blood (aplastic anemia) The syndrome consists of intermittent attacks of vertigo, epistaxis and, what is more characteristic, gingival hemorrhage, "bruises" without any history of trauma, "spots" on the skin, abnormal and persistent pallor, and a feeling of depleted vitality The exhibition of all or some of these symptoms by a worker in heliogravure should serve as an adequate warning and calls for a thorough hematologic examination Therapeutic measures are in these cases thus far purely symptomatic and are identical with those used in aplastic anemias of any sort It is impossible for the workers to take prophylactic precautions, a worker can hope to avoid the intoxication only by discontinuing his work Prophylactic measures are possible, however, but it will be necessary to recommend their adoption through official channels

Medical Service for Colonial Natives

The Queen Elizabeth foundation for providing the colonial native population with medical attention (*Fondation Reine-Elisabeth d'assistance medicale aux indigenes* [Foream]) created in 1930, has received from the Belgian government and the government of the Belgian Congo an endowment of 200,000,000 Belgian francs. In addition the foundation has benefited by numerous voluntary donations, notable among which is the personal gift of Queen Mother Elizabeth herself.

The organization has as its objective the improvement of health and hygiene among the indigenous population in the Belgian Congo as differentiated from the European colonials. At present the Foream in addition to caring for the sick in hospitals, dispensaries and ambulant units is taking a demographic census of the native population. The society also does social welfare work such as the care of mothers and children. To carry on, the foundation employs, in addition to native personnel, twenty-nine physicians, twenty-one white health officers, all graduates of the Institute for Tropical Medicine at Antwerp, and 125 white graduate women nurses.

Industrial Medicine

A government edict has reorganized the Industrial Inspection Service. As a unit of the general occupational protection authority a special corps of physicians has been assigned to protect the health of workers. This corps is formed from those members of the industrial medical service who hold a doctor's degree in medicine, surgery and obstetrics. The mission of the reorganized medical service is (a) to supervise and control the organization by industrial employers of instruction in hygiene for apprentices, the details of procedure to be established by edict, (b) to assist in effecting the proper occupational orientation of apprentices, (c) to make a detailed study of occupational physiology and pathology, (d) so to coordinate the information accumulated in this field that it may prove useful to all branches of welfare work, (e) to undertake at least once each month a medical examination of all those persons practicing occupations (in industrial plants or elsewhere) in which a recognized risk of contracting an occupational disease is present and further, to maintain an up-to-date record of the health of each worker examined, (f) to preach the fundamentals of occupational prophylaxis to the workers and to promote practical sanitary measures among them, (g) to supervise the enforcement of legally prescribed regulations of a medical nature.

The Tenth Congress of the International Association of Physicians

The convention of the International Association of Physicians was held at Brussels. The president of the Belgian Medical Federation, Dr Mattlet, before welcoming the foreign delegates, paid tribute, while the assembly stood to the memory of Queen Astrid. Dr Tornel, delegate from Spain and president of the tenth convention, likewise honored the memory of the queen of the Belgians, who had so well understood her role of sovereign and of mother. Dr Tornel then gave his address of welcome. He commented on the questions appearing in the order of the day and took occasion to refute the opinion prevalent in some quarters, that professional medical groups are exclusively concerned with the material interests of physicians. The speaker stressed present-day medicosocial trends. It is not necessary, he said "that the social concepts of the present should destroy those secular principles and he further affirmed that 'if those principles are respected the medical profession far from opposing progress will cooperate loyally in the best interests of the sick and of society'."

Final Homage to Father Damien

The mortal remains of Joseph Veuster known in religion by the name of Father Damien the priest who sacrificed himself for the lepers of the Island of Hawaii have finally forty-

seven years after his death, been returned to his native land. The king, the highest dignitaries of church and state and a crowd numbering thousands were all on hand to await the arrival of the training ship *Mercator*, which bore the body homeward. Father Damien was born at Tremeloo in 1840. In 1873 he sailed away to take up his voluntary exile at the leper colony on the island of Molokai. In 1876 he became aware that he himself had become infected with the disease and thus he revealed in his daily discourse, no longer referring to the sick as "my brothers" but as "we who are afflicted with leprosy." He died in 1889. The casket was borne to the cathedral with great solemnity, 300 members of the obscure hero's family marched in the cortege. Later, passing by way of the little village of Tremeloo, the remains were brought to Louvain, where the interment took place.

BUENOS AIRES

(From Our Regular Correspondent)

July 2, 1936.

The Adrenals and Diabetes Mellitus

According to Houssay and Biasotti, adrenalectomy diminishes pancreatic diabetes in toads as much as hypophysectomy does. The effect produced by the removal of the hypophysis and both adrenals is not greater than that produced by the removal of only one of these glands. Adrenal cortex extract given to the animals with pancreatic diabetes, attenuated by adrenalectomy or hypophysectomy, fails to intensify the condition, which is intensified by administration of the anterior lobe of the hypophysis. This fact proves the veracity of the statement given by the authors in 1933 and 1935, according to which the hypophysis has a diabetogenic action in which the adrenals play no part. The reason of the attenuation of pancreatic diabetes after adrenalectomy is unknown. Probably the attenuation is due either to suppression of still unknown adrenal hormones or to inhibition of the hypophysis, but the problem is still unsolved.

Honors Conferred on Foreigners

The Academia Nacional de Medicina has appointed the following persons honorary fellows: Drs George Marmescu, Harvev Cushing, J B Morelli, W B Cannon, A Austre gisilo, Lucas Sierra and Carlos Charlin.

Medical Lectures

Dr J B Morelli of Montevideo lectured recently in Buenos Aires on polycystic lung and on giant emphysema, associated with a lesion of the pulmonary artery, in several members of a family.

Prof G Mouriquand of Paris will give, in the near future a series of lectures on pediatrics and medical climatology. Dr Fred H Albee is expected soon to visit the several medical centers of Buenos Aires for a week.

Effects of Acetylcholine

Drs Battro and Lanari performed intra-arterial injections of 0.04 Gm of acetylcholine in human subjects. The injection at the femoral artery caused the following symptoms in the area supplied by the artery: intense redness, slight pain, perspiration, pilar erection and increase of the amplitude of the pulse wave. These modifications differentiate the presence of the spastic from that of the organic factor in diseases of the peripheral arteries because they appear in cases of arterial spasm but not in cases in which there are organic arterial lesions. Aside from the symptoms mentioned the injection made at the humoral artery produces a contracture of the muscles of the injected forearm and hand which lasts from thirty seconds to a minute in patients suffering from myotonia and is absent normally. The injection made at the carotid artery in normal persons produces redness, perspiration and miosis of the pupils.

the face corresponding to the side on which the injection is performed and salivation, and, as general symptoms, motor agitation and sometimes conjugate deviation of ocular movements, nausea, bradycardia and irregularities of the cardiac rhythm with auricular fibrillation. There are no accidents complicating the injection, the effects of which rapidly disappear.

Deaths

Dr Telemaco Susini, formerly professor of pathologic anatomy, who introduced bacteriology in Argentina, honorary member of the Academia Nacional de Medicina, has died, aged 83.

Dr Arturo Zabala, head of the Hospital Rivadavia, ex president of the Sociedad de Cirugia and an honorary member of the Academia Nacional de Medicina, is dead.

Granulocytopenia and Aminopyrine

The *Nederlandsch tijdschrift voor geneeskunde* has published a series of monographs by Vries, Groen and Gelderman on angina agranulocytotica—granulocytopenia. Over a three year period thirteen cases, several of them fatal were observed in which the principal etiologic factor was the use of some medication. In two of these cases the disorder followed an injection of arsphenamine, in nine absorption of aminopyrine or antipyrine was inculpated. In two doubtful cases the possibility of the use of barbitol or its derivatives was not excluded. In five additional cases the manifestation followed precisely after the use of aminopyrine. The latter are reminiscent of similar cases described by American and Danish authors. A checking by the leukocytic formula should be regularly a part of any therapy that involves the use of antipyrine and aminopyrine.

Since the publication of these articles, numerous others have appeared in different countries. The foregoing authors themselves have recently made first hand observations of four new cases two of these were fatal and one (that of a physician) was extremely grave. A Polak Daniels and Heybroek have just described two other fatal domestic cases.

The arguments already advanced in support of an etiologic relationship between the use of aminopyrine and subsequent disturbances are substantiated by the established fact that in Denmark, where the medical profession has been induced to refrain from the prescription of the drug, not a single case of angina agranulocytotica has appeared. On the other hand, Madison and Squiers and Plum and von Bonnsdorff have observed several recovered cases in which a recurrence of manifestations (shivering, decrease in the number of white corpuscles) took place when the use of aminopyrine was renewed. The Council on Pharmacy and Chemistry in America and Adams in England have warned against its use.

In case of necessity, aminopyrine might be administered without detriment to the hospitalized patient who is under regular hematologic control. But the Dutch authors consider that in many cases the administration of this substance could be advantageously superseded by other procedures. In any event the unrestricted and frequently protracted use of aminopyrine by so many persons and for such a diversity of ailments should be prohibited. Furthermore, these authors are unanimously agreed that angina agranulocytotica is not an aminopyrine intoxication but rather an idiosyncratic manifestation in certain subjects. This hypersensitivity may be congenital or may erupt only after the addiction has lasted for a period of months or of years without apparent ill effect.

Experimental studies such as those undertaken by Miller and by Climenko perhaps offer something of an insight into the influence of aminopyrine on the bone marrow. But it would

be foolish to expect the publication of such data to effect any substantial curtailment of the current abuses. This is a difficult problem all the more so as the manufacturers of pharmaceutical 'specialties' are wont to conceal the true nature of their products behind a varied and fantastic nomenclature.

Regulation of Medical Service for Aviation

New legislation (of Oct 26, 1935) to govern the medical supervision of aerial navigation has just been made public. The following points are worthy of attention.

The physician attached to an airport has the right before the taking off or after the landing of an aircraft to make a medical examination of the passengers and crew whenever circumstances justify such a procedure. This examination must entail no expense to the person examined and it must take place at the same time as the usual police and customs inspections in order to obviate all delay and not to hamper the continuation of a journey.

The official in charge of an airport shall see to it that, excepting in case of the transportation of sick persons in a craft especially set aside for them, no person who presents the symptoms of any one of the contagious diseases mentioned in article I of the statute, on the suppression of contagious disease, shall be permitted to embark without the favorable recommendation of the physician attached to the airport. If the physician is momentarily absent, the authorities of the airport can defer the departure of the sick person pending the required recommendation of either the medical officer or some other physician. The contagious diseases in question are plague, cholera, yellow fever, exanthematous typhus and smallpox.

The competent authority of the airport will see to it that on arrival of an aircraft which is subject to inspection by the medical officer the craft shall remain in isolation until the examination has been concluded. Similarly, no aircraft will be permitted to leave an airport until the compulsory medical inspection has been carried out.

The members of the ground personnel at the field are allowed to furnish all such assistance as may be necessary to assure the safety of the craft and of the airport, but they must do their utmost to avoid contact with the crew or passengers.

If an aircraft liable to medical inspection should land elsewhere than at an airport, its commanding officer is compelled to communicate immediately with the burgomaster of the commune in which he finds himself. The commanding officer must see to it that his craft remains as isolated as the necessary assistance of third parties in the landing will permit.

Marriages

JAMES BRECKINRIDGE LOUNSBURY, Ann Arbor, Mich., to Miss Beatrice Thomen of St George, S I, New York, July 11.

HAVELOCK FRANK FRASER, Bellingham, Wash., to Miss Dorothy Bishop Cassel of Decatur, Ga., recently.

JOHN ALEXANDER, Ann Arbor, Mich., to Miss Emma Woolfolk of Detroit at Canandaigua, N Y, July 11.

THOMAS LOWRY, Minneapolis, to DR. ELIZABETH PANET CHITTENDEN of New York, July 3.

BERNARD A FLESCH, Lake City, Minn., to Miss Kathleen Cecile Dohan of St Paul, July 9.

LOUIS J HIRSCHMAN, Detroit, to Mrs Hanna C Kellogg of Battle Creek, Mich., August 15.

CARL OSCAR LUNGERHAUSER of Newton, Ga., to Miss Helen Jones of Bainbridge, recently.

RICHARD P STRONG to Miss Grace Nichols, both of Boston in London, England, July 23.

VICTOR ANDRE DIGILIO to Miss Elizabeth Leedes, both of Philadelphia, recently.

JOSEPH B WOLFFE to Miss Evelyn Leedes, both of Philadelphia, August 9.

Deaths

Mayer Harris Lebensohn ☉ Chicago, Hahnemann Medical College and Hospital, Chicago, 1895, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, formerly vice president and counselor of the Chicago Ophthalmological Society, instructor in ophthalmology at the University of Illinois College of Medicine, Chicago, from 1907 to 1914, for many years attending ophthalmologist to the Illinois Charitable Eye and Ear Infirmary, Mount Sinai Hospital, Orthodox Jewish Home for the Aged and the Marks Nathan Jewish Orphan Home, aged 71, died, June 26, at the Mayo Clinic, Rochester, Minn., of embolism following a minor surgical operation

James Franklin Ackerman ☉ Asbury Park, N. J., New York Homeopathic Medical College and Hospital, 1890, past president of the Monmouth County Medical Society, formerly president of the board of education and library association served in the secret service during the World War, fellow of the American College of Physicians, was chairman of the board of governors of the Marlboro (N. J.) State Hospital and member of the board of governors of the Allenwood (N. J.) Sanatorium and Monmouth County Hospital for Tuberculosis, aged 71, president of the board of governors of the Fifth Memorial Hospital, Neptune, where he died, August 5

Richard Olding Beard ☉ Minneapolis, Chicago Medical College, 1882, secretary from 1888 to 1903 and from 1906 to 1925 of the University of Minnesota Medical School, and director of the department of physiology from 1888 to 1912 and professor from 1888 to 1925, when he became emeritus professor, from 1925 to 1932 executive secretary of the health council of Minneapolis and Hennepin County, honorary fellow, formerly secretary, vice president and president of the Minnesota Academy of Medicine, aged 79, died, August 14

James Burnside Wands Lansing, Tenafly, N. J., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, member of the Medical Society of New Jersey, past president of the Bergen County Medical Society, for many years member of the local board of health and medical inspector of the public school system, on the consulting staff of the Englewood (N. J.) Hospital, aged 78, died June 9, in Paramus, of carcinoma of the sacrum and prostate

Charles Everett MacDonald ☉ Major, U. S. Army, retired, Woodstock, Vt., New York University Medical College, 1896, served in the medical reserve corps of the U. S. Army for many years, veteran of the Spanish-American and World wars entered the medical corps of the regular army as a major in 1920 and was retired in 1930 for disability in line of duty, aged 62, died, June 20, in St. Elizabeth's Hospital, New York, of pneumonia, following an operation for gastric ulcer

Edward Daniel Hurley ☉ Boston, Harvard University Medical School, Boston, 1904, member of the American Academy of Ophthalmology and Oto-Laryngology and the New England Ophthalmological Society fellow of the American College of Surgeons, aged 54, consulting ophthalmologist to the Choate Memorial Hospital, Woburn, and St. Mary's Infant Asylum, ophthalmic surgeon-in-chief to the Carney Hospital, where he died June 8 of coronary sclerosis

Arthur Brown Chase ☉ Oklahoma City, Harvard University Medical School, Boston 1892 professor of clinical medicine, University of Oklahoma School of Medicine past president of the Oklahoma County Medical Society, counselor of the Fourth District of the Oklahoma State Medical Association fellow of the American College of Physicians, aged 66 on the staff of St. Anthony's Hospital where he died, July 20 of subarachnoid hemorrhage due to a fall

Richard N. W. K. Horner ☉ Watkins Glen, N. Y., University of the City of New York Medical Department, 1887 health officer of the consolidated health district comprising the towns of Dry, Reading and the village of Watkins Glen aged 73, died, June 17, in the Robert Packer Hospital Sayre, Pa. of carcinoma of the esophagus and arteriosclerotic cardiovascular disease

Titian J. Coffey, Los Angeles, University of Southern California College of Medicine, Los Angeles 1898 University of Pennsylvania Department of Medicine, Philadelphia 1899 fellow of the American College of Surgeons at one time assistant professor of obstetrics at the University of California Medical Department aged 62 died July 31

Philip Ball Moss ☉ Selma Ala. Johns Hopkins University School of Medicine Baltimore, 1909 past president of the Dallas County Medical Society recording secretary of the

Y. M. C. A., board of directors, for many years state bacteriologist, on the staff of the King Memorial Hospital, aged 52, died, June 4, of heart disease

Richard H. Edmondson, Morgantown, W. Va. Hahnemann Medical College and Hospital of Philadelphia, 1890 member of the West Virginia State Medical Association, formerly city and county health officer, served during the World War aged 69 formerly on the staff of the Monongalia County Hospital, where he died, June 20

John Bunting Haines, Philadelphia, Jefferson Medical College of Philadelphia, 1916, member of the American Urological Association, on the staffs of the Hospital of the Protestant Episcopal Church, Philadelphia and the Delaware County Hospital, Drexel Hill, aged 46, died, June 28, of cerebral hemorrhage and hypertension

Walter Henry Mytinger ☉ La Fayette, Ind., Ohio-Miami Medical College of the University of Cincinnati 1912, served during the World War, medical officer of the Veterans Administration in Indianapolis, superintendent of the William Ross Sanatorium, aged 51, died suddenly, June 13, of cerebral hemorrhage

Omer Atherton Newhouse ☉ Major, U. S. Army, retired, San Antonio, Texas, Rush Medical College, Chicago, 1900 served during the World War, entered the medical corps of the U. S. Army in 1920 as a major, was retired in 1934 for disability in line of duty, aged 59, died, June 5, in the Station Hospital

Thomas W. Lauterborn, Montclair, N. J., University of the City of New York Medical Department, 1880, at one time on the staffs of the Essex County Isolation Hospital for Contagious Diseases, Belleville and the Essex Mountain Sanatorium, Verona, aged 77, died June 13, of pulmonary tuberculosis

William Thomas McKinney, Cave Spring, Ga., Vanderbilt University School of Medicine, Nashville, Tenn., 1893, member of the Medical Association of Georgia, for many years on the staff of the Georgia State School for the Deaf, aged 71, died, June 3, in a hospital at Rome

George Rustedt, Rutland, Vt., University of Vermont College of Medicine, Burlington, 1876, member of the Vermont State Medical Society, formerly city health officer, aged 84, for many years on the staff of the Rutland Hospital, where he died, June 18, of uremia

Attilio Francis Galasso ☉ Morristown, N. J., Columbia University College of Physicians and Surgeons, New York, 1930, secretary of the Morris County Medical Society clinical pathologist to the Morristown Hospital, aged 31, died, June 29, of coronary embolism

Marietta Haslep, Indianapolis University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883, at one time a medical missionary in China formerly member of the school board, aged 70, died, June 2, in the City Hospital, of a fractured humerus due to a fall, and hypostatic pneumonia

Carl Gilbert Lundquist ☉ Leola S. D. Rush Medical College Chicago, 1919, past president of the Aberdeen District Medical Society, aged 52, died, June 26, in St. Luke's Hospital, Aberdeen, as the result of injuries received in an automobile accident

Drayton Margart Crosson, Leesville S. C., University of Tennessee Medical Department, Nashville, 1883, member and past president of the South Carolina Medical Association, formerly state senator and mayor of Leesville, aged 77, died July 16

E. Earl Houck ☉ Du Bois, Pa. Baltimore Medical College 1906, fellow of the American College of Surgeons, on the staff of the Du Bois Hospital and the Maple Avenue Hospital aged 55, died, June 27, of coronary occlusion and arteriosclerosis

William Haight Madison, Silva, N. C., Tulane University of Louisiana School of Medicine New Orleans, 1929 member of the Medical Society of the State of North Carolina aged 33, died, June 16, of a self-inflicted bullet wound

George Harold Jamieson Oshkosh, Wis. Marquette University School of Medicine Milwaukee, 1927 member of the State Medical Society of Wisconsin aged 36, died June 15 of carcinoma of the lumbar vertebrae and bladder

Emanuel Bernard Fink ☉ Chicago, Rush Medical College Chicago 1920 professor of pathology and bacteriology at the Chicago College of Dental Surgery on the staff of the Cook County Hospital aged 46, hanged himself, June 16

Edward Joseph Novotny, Lorain Ohio St. Louis University School of Medicine 1921 member of the Ohio State Medical Association on the staff of St. Joseph's Hospital, aged 41, died suddenly June 17 while playing golf

Juniattus A Fisher, St Louis St Louis College of Physicians and Surgeons, 1899, member of the Missouri State Medical Association, aged 63, died, June 16, in the Missouri Baptist Hospital of carcinoma of the lung

Dewey Aday, Bartlesville, Okla., University of Arkansas School of Medicine, Little Rock, 1930, member of the Oklahoma State Medical Association, aged 37, died, June 9, of an accidental overdose of procaine hydrochloride

Clayce Remine De Forest, Clarksburg, W Va University of Maryland School of Medicine, Baltimore 1920 aged 44 died, June 15, in the Hillview Farms Sanitarium Washington, Pa, of pneumonia and chronic nephritis

Henry S Wahl, Wausau, Wis., Chicago Medical College, 1884 member of the State Medical Society of Wisconsin aged 75, died, June 12 in a hospital at Kansas City, Kan, as a result of hypertrophy of the prostate gland

Lucius Henry Hayman Pasadena, Calif Rush Medical College, Chicago, 1878, member of the State Medical Society of Wisconsin, formerly a practitioner in Boscobel Wis., Civil War veteran, aged 90, died, June 3

William Gardner Gabie, Seattle, McGill University Faculty of Medicine Montreal, Que., Canada, 1907, member of the Washington State Medical Association, aged 57, died June 25, of coronary thrombosis

John Elmore Bailey, Middletown Conn., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, member of the Connecticut State Medical Society, aged 73, died, June 5

Arthur Leo Curtis, Washington, D C Howard University College of Medicine, Washington, 1912 aged 46 died June 28 in Castle Point, N Y, of chronic pulmonary tuberculosis and tuberculous laryngitis

Harvey Peter Hess, Pine Grove, Pa Hahnemann Medical College and Hospital of Philadelphia, 1896 formerly bank president, and member of the school board, aged 64, died, June 22, of cerebral hemorrhage.

Charles M. Headrick, Plattsmouth, Neb., College of Physicians and Surgeons, Keokuk, Iowa, 1876 College of Physicians and Surgeons of Chicago, 1896 aged 82, died June 4, of hypostatic pneumonia

Joseph M. Parker, Oron Hill, Md College of Physicians and Surgeons, Baltimore, 1878, aged 82, died, June 9 in the Providence Hospital, Washington, D C, of congestive heart disease and mitral stenosis

James Ellsworth Holmes, Columbus, Ohio, Starling Medical College, Columbus, 1892, member of the Ohio State Medical Association, on the staff of the Grant Hospital, aged 72, died, June 19, of heart disease.

Andrew Douglas Carter Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1895 aged 64, died June 21, in Ocean City, N J, of hypertension and arteriosclerosis

S Dugan Graves, Bastrop, La., Louisville (Ky) Medical College, 1904, member of the Louisiana State Medical Society, for many years deputy coroner, aged 51, died, June 28, of angina pectoris

Samuel Blair, Apache, Okla., Hospital College of Medicine, Louisville, (Ky) 1887, member of the Oklahoma State Medical Association, aged 85, died, June 13, in a hospital at Lawton of heart disease.

Charles P Bacon Evansville, Ind., University of Pennsylvania Medical Department, Philadelphia, 1861, aged 99, died, June 18, of acute dilatation of the heart and hypostatic pneumonia.

William Edgar Williams, McBee, S C, Medical College of Virginia, Richmond 1916, served during the World War aged 46, died May 24, in a hospital at Hartsville, of toxic hepatitis

William Preston Haynes Washington D C George Washington University School of Medicine, 1924, aged 36, died, June 29, of a ruptured esophageal varix and cirrhosis of the liver

Ezra Leslie Meads, Loose Creek, Mo Bennett Medical College, Chicago, 1914, served during the World War, at one time county coroner, aged 43, died June 11, of angina pectoris

George E Clements Crawfordsville, Ind., Rush Medical College, Chicago, 1900, served in the Canadian Army during the World War, aged 65, died, June 17, of cerebral hemorrhage.

Charles Albert Fisher, Los Angeles, College of Physicians and Surgeons, Los Angeles 1913, member of the California Medical Association, aged 58, died, June 19, of heart disease

Murdock Lloyd Davis, Allenton, Mich., Trinity Medical College, Toronto, Ont., Canada, 1877, aged 86, died, June 3, in the University Hospital, Ann Arbor, of duodenal ulcer

Frank Cramer Wright Grove City, Ohio, Starling Medical College, Columbus, 1897, on the staff of the Mount Carmel Hospital, Columbus, aged 60, died, June 23, of heart disease

Jacob Ritter Esterly, Reading, Pa., Jefferson Medical College of Philadelphia, 1891, aged 62 died June 21, in the Wernersville (Pa.) State Hospital, of chronic endocarditis

John Isaac Green, Bath S C University of Georgia Medical Department, Augusta, 1891, aged 66 died, June 3, in a hospital at Asheville, N C, of tuberculosis of the lungs

William Moody Hunt, Murdo S D Cleveland Medical College 1894, served during the World War, aged 70, died, June 18, of coronary thrombosis and cerebral embolism

Frank Leslie Gilbert North Stratford, N H Tufts College Medical School, Boston, 1898, served during the World War aged 62, died June 24, of cerebral hemorrhage

Frank D Gray, Long Beach, Calif., Medical College of Ohio, Cincinnati, 1880, formerly a practitioner in Fort Worth Texas aged 77, died, June 8, of chronic myocarditis

John Wesley Nixon, Kansas City, Mo Marion-Sims College of Medicine, St. Louis, 1896, served during the World War, aged 65, died, June 13, in Excelsior Springs

Ivory Campbell, Norene, Tenn (licensed by Tennessee State Board of Medical Examiners in 1889), Civil War veteran, aged 91, died, June 6, of bronchopneumonia

George Heller, Baltimore, Baltimore Medical College, 1897 aged 61, died, June 10, in the Johns Hopkins Hospital, of injuries received in an automobile accident.

Giovanni Grana, Rochester, N Y Regia Università di Palermo degli studi Facoltà di Medicina e Chirurgia, Italy, 1894, aged 70, died, June 26, of myocarditis

William Pancoast Blanton, Bowie, Texas, University of Louisville (Ky) Medical Department, 1893, aged 63, died, June 10, of chronic myocarditis and nephritis

Frank D Fleury Omro, Wis Ensworth Medical College, St. Joseph, Mo, 1908, veteran of the Spanish-American War, aged 60, died, June 16, of coronary disease

Jesse H King, Worthington, Pa., Western Pennsylvania Medical College, Pittsburgh, 1887, aged 75, died, June 26, of chronic nephritis and cerebral hemorrhage

Louis Canepa, New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1903, aged 55, died, June 20, of cerebral hemorrhage and myocarditis

Jerome L Artz, Camden, N J, Hahnemann Medical College of Philadelphia, 1881, aged 75, died, June 12 of chronic myocarditis and coronary thrombosis

Emma Warner Demaree, Lincoln, Neb., Northwestern University Woman's Medical School, Chicago, 1895, aged 84, died, June 14, of arteriosclerosis

William Davis, Woodbridge, N J Hahnemann Medical College and Hospital of Philadelphia, 1893, aged 70, died, June 2, of cerebral hemorrhage.

Pinkney Alexander Teat, Jackson, Miss (licensed in Mississippi in 1906), aged 58, died, May 27, in a local hospital, of pneumonia.

John P Blakely, Fort Smith, Ark Arkansas Industrial University Medical Department, Little Rock, 1893, aged 78, died, May 9

Ernest L Battelle, South Gate, Calif., Chicago Homeopathic Medical College, 1886, aged 83, died June 25, in a local sanatorium

Lewis Nye Bump, Somerville, Mass Albany (N Y) Medical College, 1893, aged 68, died, June 5, of coronary thrombosis

Francis J Drake, Wellston Ohio, Ohio Medical University, Columbus, 1894, aged 78, died, June 1, of arteriosclerosis

Ora F Thomas, Chillicothe, Ill., Chicago Medical College 1878, aged 81, died, May 27, of cholelithiasis and chronic pancreatitis

James Thomas Gallagher, Boston (licensed in Massachusetts by years of practice), aged 83, died, June 30, of myocarditis

Robert H Miles, Lyndon Kan., College of Physicians and Surgeons of Chicago 1885, aged 81, died, June 19, of senility

Charles P Taylor, Clarksburg, W Va Baltimore University School of Medicine, 1893, aged 66, died, May 24

Bureau of Investigation

RU-MARI

An "Arthritis Cure"—Essentially a Solution of
Washing Soda

Recently many inquiries have been received by the Bureau of Investigation requesting information on a product that is sold in England and the United States under the trade name "Ru-Mari"

The following letters are typical

From Los Angeles a physician writes

I am enclosing some literature on Ru-Mari and would appreciate any information you may have on the product. Can you tell me whether a chemical analysis has been made on the product?

"I Was Attacked by Arthritis—"**MR. HUGH WALPOLE**

Famous English Author of *VANESSA* and other important novels called to Hollywood from London to adapt *DAVID COPPERFIELD* to the screen tells in this unsolicited letter how

Genuine

RU-MARI

(from the United Kingdom)

relieved his suffering and saved his writing career

"When I was working at the Metro-Goldwyn Mayer studios, I was attacked by Arthritis. I was ill for some weeks in Hollywood, then went to New York and was in a hospital there getting worse all the time. I was so bad that I was taken on a stretcher aboard the *Benagaria* and attended by a doctor and nurse. When I arrived in London I was taken again on a stretcher to a nursing home. I had some fifteen doctors. Nothing gave me relief. It was told there was little if any chance I should ever be able to write again. The prospect was hopeless and dreary indeed, and the mental torture continued night and day. Shortly thereafter a friend of mine introduced a bottle of liquid which he said had worked quite successfully with numbers of people. I took a dose that night and the next morning felt much better. Then I began taking RU-MARI in earnest. Within two weeks the swelling had gone down so amazingly that the specialists were astonished. That was a year ago and I have had no touch of rheumatism at any time during the year. This is an exact true account of how RU-MARI helped me."

H. J. Walpole

HUGH WALPOLE

● IF YOU SUFFER FROM ARTHRITIS,
SCIATICA, NEURITIS

or similar ailments when caused by acid conditions DO NOT DELAY another day before trying this new scientific formula developed by a physician in Ireland and used extensively by the medical profession in Great Britain.

MR. LIONEL BARRYMORE

of stage and screen says of RU-MARI "NOTHING IN SO HELPFUL." Stricken with Barrymore found that RU-MARI is. This remarkable prescription is offered in America duty prepaid.

Send \$5.00 today for this amazing scientific preparation or \$2.00 C.O.D. plus a few cents postal charges.

Act Now to Relieve Torture!

Also from Los Angeles a hospital superintendent writes

My attention was called to a new proprietary preparation which is being marketed in California at the present time. The advertising matter supplied by the company contains testimonials from prominent members of the movie colony here.

An inquiry from New York reads in part

Can you give me any information about a preparation called Ru-Mari (alleged cure for arthritis)? I have just received the enclosed circular in regard to it from Los Angeles which you will note contains recent testimonials from Lionel Barrymore, Hugh Walpole and others.

From Columbus, Ga., a physician inquires

I am writing to you regarding Ru-Mari which is advertised to cure arthritis. It is made in England. Do you know anything about this? I should greatly appreciate any information you can give me regarding this product.

Ru-Mari is one of a list of products with the "Ru" prefix sold by Ru-Mari, Ltd., First Avenue House, High Holborn London, W.C.1. Other Ru-Mari products advertised in England include "Ru-Mex," described as a "pain relieving lotion for external application, including headaches, sprains, strains, sunburn, open wounds, bruises, etc." "Ru-Malax—a pleasant liquid Cascara preparation," and "Ru-Mol—Vitamin Capsules (A & D)"

A booklet entitled "The Treatment and Cure of Rheumatoid Arthritis, Rheumatism and Allied Ailments," bearing the London company address, describes Ru-Mari as "strongly antacid in character and capable of destroying every disease germ in the body." In the same booklet appears the statement "It cannot be too strongly emphasized that Ru-Mari is a cure and not merely a relieving agent."

The American version, "A Treatise on Arthritis and Allied Conditions," emanating from 3149 Wilshire Blvd., Los Angeles considerably modifies the curative claims. The United States postal laws prohibit promoting through the mails schemes to obtain money by means of false and fraudulent pretenses. This booklet claims that "Ru-Mari is not the product of a mass-production laboratory. It is personally and carefully compounded by its discoverer, the thoughtful, gentle, kindly Irish practitioner, Dr. William Beggs, who dedicated himself to its formulation and perfection."

According to report, one Don Eddy of Los Angeles filed the original American trade style, and later was joined by Leslie Harris, Frank W. Wead, Joseph C. Chene, Felix F. Preeg, Mark B. Speer, Isabel Hopkins and S. V. Goldfarb as partners to form the American Ru-Mari Company of 3149 Wilshire Blvd., Los Angeles.

Don Eddy is reported to have been for several years a columnist on the Los Angeles *Examiner* and later general manager of Harry Langdon Productions. He was employed (1929-1935) by the Metro-Goldwyn-Mayer Studios as a writer. The Metro-Goldwyn-Mayer stationery is prominently featured in the Ru-Mari testimonial letter of cinema actor Lionel Barrymore ("Ars Gratia Artis"). Another testimonial letter widely circulated by the promoters in furthering the sale of their product is from the pen of Hugh Walpole, prominent English fiction writer.

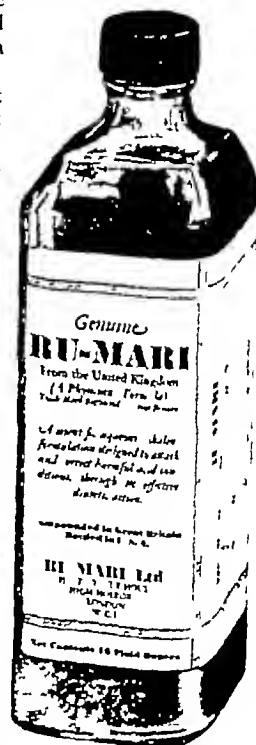

The trade package of Ru-Mari, bottled in the U.S.A., modestly claims the nostrum to be "a scientific aqueous alkaline formulation designated to attack and correct harmful acid conditions through its effective diuretic action."

Three original packages of Ru-Mari purchased direct from the American Ru-Mari Company were submitted to the A.M.A. Chemical Laboratory for examination at the request of the Bureau of Investigation. The Laboratory report follows:

LABORATORY REPORT

Each bottle contained about 475 cc. of an amber-colored liquid with a slight aromatic odor, saline and bitter taste, basic reaction to litmus and with a specific gravity of 1.006 (25°C.). The liquid was clear with a few particles of suspended flaky material.

Qualitative tests indicated the presence of the following: Chlorides, sodium, potassium, carbonates and small traces of

tartrates, sulfates, nitrogen, and phosphates. Bromides, iodides, salicylates, acetates, heavy metals, nitrates, magnesium, calcium, neocinchophen, cinchophen, emodin bearing (laxative) drugs, uva ursi, antipyrine, colchicine, cimicifuga, salophen, aminopyrine, capsaicin and pinene were not found.

"Quantitative determinations yielded the following

| | Per Cent |
|--|----------|
| "Total solids (100 cc) | 1.14 |
| Ash | 1.06 |
| Sulfated ash | 1.52 |
| Alkaline chloroform extract | 0.0 |
| Acid ether extract | 0.07 |
| Titrateable alkalinity (calculated as OH ⁻) | 0.18 |
| Titrateable carbonates (calculated as CO ₃ ⁻) | 0.28 |
| Sodium | 0.37 |
| Potassium | 0.11 |
| Organic material | 0.04 |

"From the foregoing, it may be calculated that the product contains approximately 0.65 per cent sodium carbonate (Na₂CO₃, anhydrous) equivalent to 1.76 per cent hydrated sodium carbonate (washing soda) and 0.30 per cent potassium hydroxide (lye) with a trace of organic material.

"A product essentially similar may be prepared by dissolving 1.76 Gm. of washing soda and 0.3 Gm. of pure lye in water to make 100 cc of solution."

Thus Ru-Mari is a typical nostrum, essentially an alkaline solution, advanced as specific for conditions in which it could not possibly have specific effects, and supported by testimonials from persons better known for artistic attainment than for medical knowledge or scientific judgment.

Correspondence

ELIMINATING ODOR OF GARLIC

To the Editor—M. A. Blankenhorn and C. E. Richards (*THE JOURNAL*, August 8, p. 409) present the results of certain experiments which they interpret—quite erroneously—into a sweeping refutation of work previously reported by L. A. Greenberg and me (*THE JOURNAL*, June 16, 1935, p. 2160) demonstrating that the odor on the breath after eating onions or garlic arises from material retained in the mouth. Blankenhorn and Richards believe that the odor comes wholly from essential oil passed into the blood stream during digestion and aerated out in the lungs.

Their experiments were ingenious if incomplete. They gave garlic soup and garlic oil by stomach to a patient with stenosis of the esophagus and three hours later observed by sense of smell a garlic odor on the breath. To one of two patients with occlusion of the larynx they fed garlic salad and garlic oil, again some three hours later they noticed a fouling of the breath as it came out of the tracheal opening. These would appear to be conclusive demonstrations of their thesis that garlic odor reaches the breath wholly by way of the blood stream, but in reality Blankenhorn and Richards, in their eagerness to prove their point, have intentionally or unintentionally failed to quote a statement made in our paper thereby casting an entirely false interpretation on our work.

Our statement concerns the previous investigation of F. A. Lehmann (*Untersuchungen über Allium sativum* [Knoblauch], *Arch f exper Path* 147:245, 1930), who gave garlic extract by stomach tube to rabbits and determined, by chemical analysis, the amount of the oil reaching the expired air from the blood stream. Concerning this work we said: "The doses of oil he used were enormous, from 4 to 5 cc. of the juice pressed from garlic and containing from 8 to 10 mg. of essential oil. This amount would be equivalent to 6 to 8 Gm. of the vegetable. Such a dose, given to a rabbit weighing 1.5 Kg., would correspond to 300 or 400 Gm. of garlic given to a man. The amount of oil appearing in the expired air was so slight as to fall within the limits of the error of the method of analysis definitely less than 1 per cent of the oil appearing in the

breath in spite of the massive dose that had been given. Lehmann's work really offers no support to the belief that the odor on the breath after eating ordinary amounts of onion or garlic comes from the blood by way of the lungs."

Blankenhorn and Richards (carefully avoiding quantitative methods) give no indication of the amount of garlic administered but only of the oil. They gave 400 mg. to their subjects before they could detect the odor on the breath after a lapse of three hours. They simply repeated Lehmann's old experiment, on which we had commented: "400 mg. of oil is the yield from one-half to 1½ pounds of garlic. We are willing, indeed anxious, to concede that any one eating a pound of garlic at one sitting may have the odor in the blood as well as in the mouth, but our point was, and still is, that no one eats a pound of raw garlic. Our experiments were carried out with amounts within reason and with such no appreciable amount of oil appears in the blood stream. We proved this point by administering to our subjects garlic sealed in gelatin capsules, the breath was not tainted and no oil could be found in it by chemical analysis."

The significant point, however, is the time elapsing between the ingestion of the garlic and the appearance of the odor. If the smell comes from the blood following digestion, minutes or hours must pass before the breath is tainted. This delay is contrary to common experience in eating onions: the characteristic odor appears immediately. In the experiments of Blankenhorn and Richards, some three hours elapsed even after the massive doses of garlic oil before the odor was detected on the breath.

Blankenhorn and Richards, with every facility at hand, did not carry out the obvious experiment—really a control for their experiments—of having their patient with esophageal stricture chew garlic and then spit it out. None of the essential oil could reach the blood stream but I can assure them that their patient's breath would nevertheless have smelled so strong that it would be unnecessary to call in disinterested witnesses to prove fouling—the whole hospital ward would have testified to it. I cannot understand why Blankenhorn and Richards failed to carry out this procedure unless they were more anxious to throw discredit on our work than to discover the facts. It is fortunately an experiment that any one can perform to prove to himself that the odor comes from the mouth and comes from there, not after a delay of three hours, but immediately.

Blankenhorn and Richards, scrupulously avoiding quantitative methods, depending wholly on the uncertain criterion of faint smell, and recording no observations as to whether or not their subjects' breaths were foul before the tests, have made no attempt to duplicate our perfectly simple experiments. Yet they have no hesitation in saying that the chloramine solution we find effective in destroying mouth odor merely "masked" the garlic smell. This they attempt to show by using a chloramine mouth wash eighteen hours after feeding an unstated amount of garlic.

Since publishing our work we have tested for deodorizing properties numerous mouth washes and find a diluted solution of sodium hypochlorite to be somewhat more effective than the chloramine we originally recommended. The hypochlorites destroy garlic oil in a test tube as well as in the mouth, but they have no persistent odor that would disguise the smell of garlic. Only those substances which actually break down chemically the odoriferous substance are effective deodorants. And this is not our conception of "masking" an odor. The hypochlorites have no effect whatever on the breath odor from alcohol, which definitely emanates from the blood stream.

HOWARD W. HAGGARD, M.D., New Haven, Conn.

Yale University

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ARSPHENAMINE REACTIONS

To the Editor—I have been treating a recently acquired case of syphilis in a healthy Negro weighing about 150 pounds (68 Kg.) I started him on 0.6 Gm of neoarsphenamine and he became a bit nauseated. During the following week I repeated the dose and he had to go to bed with extreme joint pains and nausea and vomiting. This lasted several days and I had to discontinue its use. I then commenced a series of six injections of bismuth salicylate in oil with no untoward consequences. On their completion his strongly positive reaction became negative Kolmer and plus minus Kahn. I then tried to give him a series of bismuth arsphenamine sulfonate but ten minutes after the first injection (intramuscularly) he became nauseated and ill. This lasted for almost one hour. I immediately discontinued all arsenic and merely gave him a weekly injection of bismuth salicylate associated with 0.65 Gm of potassium iodide three times a day. Is there any other arsenical I might safely try in this case or must I stick to bismuth? I see no advantage in adding mercury since I feel that bismuth supplants it. Also if I make him blood and spinal fluid negative under my regimen when shall I quit and what shall be his further care? Also if on subsequent examinations he again becomes positive, what should be my procedure? In a nutshell my patient has been unable to withstand a small dose of neoarsphenamine and also bismuth arsphenamine sulfonate intramuscularly. However three doses of neoarsphenamine brought him down from 4 plus to plus Kahn. After about fifteen doses of bismuth salicylate in oil, his blood test shows 1 plus instead of \pm his Kolmer showing moderately positive against negative after the three doses of neoarsphenamine. In other words continued treatment with bismuth salicylate alone shows a gradually returning positive blood test. That means he cannot tolerate small doses of arsenic, and bismuth alone apparently is doing him no good. I am wondering whether mercury injections would help him and if so, what procedure I should follow. Please omit name. M D Maryland

ANSWER.—It is difficult to identify the type of arsphenamine reaction from the description given. Only two types of arsenical reactions signify definite sensitization to the drug, namely, dermatitis and the blood dyscrasias. While there is no evidence of dermatitis in this case, it is possible that the extreme joint pains, nausea and vomiting lasting for several days may signify a blood dyscrasia. It is essential to be sure of this point because, if it is at all possible to do so the patient's treatment must be continued with an arsphenamine.

The only other type of immediate reaction that tends to recur after repeated injections of the drug is the angioneurotic symptom complex usually manifested by the so-called nitritoid crisis. This reaction may be avoided by very slow administration of the drug or by the preliminary administration of epinephrine or atropine. The description given does not sound like the nitritoid crisis.

Mild gastro-intestinal reactions, lasting from a few hours to as long as twenty-four hours, may occur in approximately 50 per cent of patients treated with the arsenical drugs. They may be in part eliminated by regulation of the bowels, by omission of a meal immediately preceding treatment and by a light meal after treatment. Such mild gastro-intestinal reactions that do not depend on an underlying cause, such as hepatitis, a blood dyscrasia or the angioneurotic symptom complex, should be disregarded in the treatment of a patient with early syphilis. It is so important to administer the arsenical drugs from the standpoint both of the public health and of the patient's ultimate outcome that the patient should be urged to put up with the minor inconvenience of such reactions.

Mapharsen recently introduced into the treatment of syphilis, is a drug that probably does not cause the angioneurotic type of immediate reaction and causes gastro-intestinal reactions in a somewhat lower proportion of cases than the arsphenamines. It is suggested that this patient's treatment be recommenced with mapharsen. In order to rule out the possibility of a blood dyscrasia it would be wise to start with a very small dose, i. e. 10 mg., following which a white and differential count should be done at twenty-four hour intervals for the next three days. If the white count is significantly reduced, i. e., below 4000 and if this reduction is particularly at the expense of the granulocytes this should be taken as an indication that further administration of any of the arsenical drugs might produce agranulocytosis or aplastic anemia. If also there is any sign of bleeding from the gums or of cutaneous purpura it

may be assumed that the blood platelets have been damaged and that further arsenical treatment may cause a genuine and serious thrombocytopenic purpura. If, however, there is no change in the blood count and no bleeding, the dose should be cautiously increased by 10 mg increments until the average therapeutic dose of 60 mg is reached. If this can be done without producing serious reaction, further treatment should proceed by the method suggested by the Cooperative Clinical Group, with mapharsen substituted for arsphenamine, for example, courses of ten injections of mapharsen alternating with courses of from six to eight injections of bismuth salicylate treatment being given continuously for a minimum period of eighteen months.

The present tendency of the blood serologic test to relapse to positive may be due to asymptomatic neurosyphilis, and the patient's spinal fluid should be tested promptly.

If the patient is really intolerant to the arsenical drugs and cannot take them because of dermatitis or a blood dyscrasia, and if the spinal fluid is negative, treatment must be continued with bismuth compounds and mercury alone. In view of the small amount of arsenical treatment so far given, the total duration of treatment should be from three to five years and during this period it should so far as possible be continuous with courses of intramuscular bismuth compounds alternating with courses of mercury by injection. This amount of treatment should be given arbitrarily, regardless of when the patient's blood serologic test becomes negative.

If the spinal fluid is positive and if actually intolerant to trivalent arsenical drugs, it probably will be possible to use tryparsamide, a pentavalent compound, without difficulty.

Mercury by injection, if properly used by the patient, is both safer and better than mercury by injection.

SYPHILIS IN CHILD AND MOTHER

To the Editor—A young couple with their first born came to me about the baby because of what they termed running ears. They had consulted three other doctors and the child had been given local treatment for the condition of the ears. The baby was 3 months old January 24. The child presented a picture of a feebly developed body shriveled countenance, fissures about the angles of the mouth and the anus bulging and eczematoid scales on the forehead and scalp. Snuffles was present and an otopyorrhea on both sides. The voice was harsh when crying. The child nursed poorly had sores in the mouth whined and fretted. Intermittent strabismus was present. The child was restless to sleep and fretful when awake. Occasional bleeding from the nose occurred. The blood Wassermann of the father was negative of the mother 4 plus. The father gave a history of a soft chancre on the penis ten years previously. He was treated and reported cured by his doctor at that time. The mother gave no history of an infection that she knew of. Three reports from blood specimens for the father were negative. I began treatment of the infant with intramuscular sulfarsphenamine 0.1 Gm. twice weekly for two weeks then weekly and shall continue so for eight doses. Since treatment of the baby was begun many symptoms have cleared and it is improving in weight and appearance. I also began treatment of the mother with sulfarsphenamine intramuscularly 3 Gm weekly. Under the circumstances found would I be justified in treating the father with three negative Wassermann tests for syphilis? What can I do more to test for positive syphilis in the father so as to get to treatment at the earliest possible moment? Would a spinal puncture be justifiable as a further test? Please speak about the virtues of the various preparations that might be indicated in these cases other than what I am now using. Any other information bearing on these cases will be greatly appreciated. Please omit name.

M D., Alabama.

ANSWER.—This inquiry deals with two fundamental problems first the treatment of congenital syphilis, second the status of the father. In a new-born baby with syphilis considerable caution must be used in the administration of an arsphenamine, because not infrequently these infants have an overwhelming spirochetemia involving particularly the liver. Under such circumstances the use of an arsphenamine preparation may result in a Hertzheimer reaction severe enough to prove fatal. As this child is apparently tolerating the arsphenamine satisfactorily its continued cautious use intramuscularly is warranted. When the sulfarsphenamine course is completed the addition of mercury to the therapeutic program in the form of mercury rubs, 2 Gm under the abdominal binder may be used. The alternate use of the sulfarsphenamine and the mercury should be continued for at least eighteen months. Sulfarsphenamine has produced blood dyscrasias and so the patient must be watched for such a complication. Bismuth arsphenamine sulfonate is another antisyphilitic remedy that may be used intramuscularly in infants and it has the advantage of combining the heavy metal bismuth with the arsenical. The subsequent treatment program is dependent on the child's reaction to the treatment and later manifestations of syphilis.

The status of the father raises two points for discussion. Has he had syphilis and been cured of it? Did the mother acquire syphilis previous to marriage and he not become infected? To settle the first issue an examination of the spinal fluid is essential, if it is found to be negative in the presence of the repeatedly negative serologic tests, treatment is not necessary. He should, however, be placed on observation and be reexamined from time to time at yearly intervals to note whether or not he subsequently develops any evidence of the disease. In regard to the second phase of this question, if the mother had acquired her infection some time previous to her marriage she might have a syphilitic child and her husband not acquire the disease from her. This seems the least probable of the two hypotheses in view of the history of the father's having had a penile lesion some years before. In either instance, treatment of the father is not warranted now unless the spinal fluid is found to be positive. However, he should have annual reexaminations both clinical and serologic.

MILKY SERUM WITH LIPEMIA

To the Editor—I have what seems to me to be a most unusual case of a girl aged 11 whose blood when removed into a test tube appears normal for the first three minutes of exposure and then begins to separate into a normal clot and an opaque milky serum which when standing separates in turn into a lower watery layer taking up about five sixths of the total volume and an upper layer of pure white taking up the remaining sixth of the volume. I have been unable to find any cellular elements in either of these layers. The blood picture is as follows: red blood cells 4 250 000 per cubic millimeter, white blood cells 9 200 per cubic millimeter, hemoglobin 75 per cent (Sahi) differential count polymorphonuclears 65 per cent, small lymphocytes 25 per cent, large lymphocytes, 5 per cent, monocytes and transitionals 5 per cent. The white cells appear normal and none were found suggesting a hyperplasia of the bone marrow or of other blood forming organs. The child weighed 51 pounds (23 Kg.). There was a small psoriasis over the upper parts of the extremities and the lower portion of the abdomen. Also there were numerous small depigmented areas on the legs which were said to be the sites of former ulcers. The tonsils were moderately enlarged and appeared to be chronically infected. The cervical glands were moderately enlarged. These were the only lymph glandular structures in the body that were palpable. The heart and lungs were clear. The spleen was enlarged about 3 cm. below the costal margin and was tender. The liver was enlarged to about the same distance below the costal margin and showed also a slight enlargement upward. There were two intractable ulcers on the shin of the right leg and these were not punched out in appearance but rather seemed to have a hyperplasia of granulations. These ulcers were said to be of the same type from which the child had suffered frequently on previous occasions. The child had scarlet fever at the age of 5, complicated by bowel obstruction and acute pancreatitis requiring operation and drainage. Her mother says that her undernourishment, poor development and chronic ulcers dated from that time. The mother and father appear healthy. Their blood shows a negative Kahn test. There are four other children in the family all of whom are in an average state of health. One of them has a congenital heart lesion possibly a patent foramen ovale which seems to be adequately compensated. Considering the peculiar reaction of the patient's serum on exposure to air I hardly see how a Kahn test could be done on her blood. I would appreciate your giving me any clue to this case which you can. I have suspected aleukemic leukemia but why should the serum appear milky in this phase of the disease? As I have pointed out the fresh milky serum shows no cellular elements whatever. I should also have said that the child's urine is negative for albumin and sugar.

M D West Virginia.

ANSWER.—The milky serum is most likely due to a lipemia and is not indicative of a leukemia. Leukemia is furthermore excluded by the normal blood examination. An aleukemic myelosis or lymphadenosis is not characterized by such a milky serum and can be diagnosed only by splenic or bone marrow puncture.

The enlargement of the liver and spleen speak for some disturbance of the reticulo-endothelial system, such as Niemann-Pick's disease, or lipid histiocytosis. In this disease, which usually affects young female children there is an accumulation of lipoids in the reticulo-endothelium of the liver, spleen and other organs. A lipemia may lead to increased deposition of lipoids in this system with hepatic and splenic enlargement. There may be bone changes.

Normally the blood contains from 0.5 to 0.8 per cent of fats and lipoids. After fat-rich foods this may be greatly increased, and after every fatty meal there may be enough fat in the blood to make it turbid. The distinctly cloudy serum in the case described speaks for a pathologic lipemia, although turbid plasma may sometimes be found with a normal lipin content. Lipemia occurs most often in diabetes, nephrosis and alcoholism, and less often in cirrhosis, jaundice and advanced tuberculosis. In diabetes the blood fat may rise to 20 per cent, and the cholesterol is also high, especially in acidosis. About 80 per cent of patients with diabetes have a blood fat above 0.67 per

cent, which is the upper normal value. It is usually between 0.7 and 1.5 per cent, and increases with the severity of the disease and the increase in fat intake.

A careful study of the lipid and cholesterol content of the blood should be made, and the skin lesions should be studied for possible lipid or cholesterol deposition as in xanthomas. In this case diabetes and nephrosis are excluded by the normal condition of the urine.

INFECTION WITH SYPHILIS FROM NEEDLE WOUND

To the Editor—1 Can syphilis be contracted from the prick of a hypodermic needle in the skin? 2 Can syphilis develop without an initial lesion? I am not referring to larger abrasions of the skin. 3 If no disease can occur without an initial lesion why encourage future Wassermann tests? These things are happening frequently but I have in my own experience or the experiences of my colleagues yet to have such a small injury show up later with a chancre. Our own technician has just recently had such an experience and is seeking all light available on the subject. If your authority has had personal experience or knows definitely of such experience among his colleagues we will appreciate such information.

M D Kansas

ANSWER.—1 Syphilis may be contracted from a prick in the skin of a hypodermic needle or of a surgical instrument, provided the needle or instrument has recently been used on a patient freshly infected with syphilis. The danger is greatest during the incubation period of syphilis and during the existence of primary or florid secondary lesions, but there is probably some danger from such contact with any patient who has had syphilis as recently as two years. Between two and five years the danger diminishes rapidly and after the fifth year of infection it is virtually nonexistent. The same comments apply to early congenital as to early acquired syphilis.

2 Syphilis can develop without an initial lesion, not only when the infection is acquired by such trauma as mentioned but also when it is acquired by the more usual forms of contact. There are numerous cases on record of direct blood stream infections in physicians, dentists and nurses following trauma with an instrument, in whom the first sign of infection was the secondary outbreak. Even the secondary lesions may be completely lacking or so trivial as to escape attention, the infection in its early stages being nearly or entirely symptomless.

3 The facts mentioned in paragraph 2 constitute the justification for a Wassermann follow up in a person exposed to syphilis by such trauma. The danger of infection, however, depends almost entirely on the duration of infection in the patient on whom the instrument was used.

4 The prophylactic treatment of such an injury should be immediate and should consist in laying open the puncture wound to the approximate depth of penetration of the needle, and the packing of the incised wound with 33 per cent mild mercurous chloride ointment, which is allowed to remain in situ for twenty-four hours.

FLUORINE IN WATER SUPPLIES

To the Editor—It is my understanding that a great deal of work has been done on the problem of the fluorine content of raw water supplies and if you could throw any light on the following subjects it would be appreciated. 1 What amount of fluorine in the raw water supply is considered objectionable? 2 Would water with a fluorine content of 1.1 parts per million be harmful? 3 Would water with a fluorine content of 1.5 parts per million be considered a definitely inferior source to one with a fluorine content of 1.1 parts per million or 0.9 parts per million? 4 Is there any treatment that would lend itself to application either before or after zeolite softening treatment, which would either eradicate or reduce the fluorine content of the water? It is my understanding that flocculation and precipitation in a lime-soda ash treatment plant sometimes reduces the fluorine content of the filtered effluent. Is this due to the precipitation of the colloids (which could be accomplished by floc formed by the addition of alum to either the untreated or the treated water) or is this due to chemical action in the lime-soda ash softening process?

LEE E. BRANSFORD M D Jacksonville, Fla

ANSWER.—1 H T Dean and Elias Elvove (*Pub Health Rep* 50 1719 [Dec. 6] 1935) report that a mild type of mottled enamel is endemic in Colorado Springs, Colo., and in Galesburg and Monmouth, Ill., where the mean annual fluoride (F) content of the municipal water supplies based on monthly examinations for a period of about one year was respectively 2.5, 1.7 and 1.8 parts per million. They also report that at Pueblo, Colo., where the fluorine content of the public water supply was 0.6 part per million, the mottled enamel index in children was negative. Ryder (*American Water Works Journal*, November 1935) reports that water containing from 0.9 to 1.0 part per million will cause a dental defect known as mottled enamel, if consumed by children of susceptible age. For children particularly sensitive, it should be below 0.7 part per million.

2 Based on experience elsewhere, such a water might be harmful to children. It is possible, however, that the other chemical constituents of a water may have an effect on the harmful properties of fluorine and might well be investigated.

3 The harmful effects seem definitely to be related to the quantity of fluorine present in the water.

4 C. S. Boruff (*Indust. & Engin. Chem.* 26:69 [Jan.] 1934) reports that

Removal of injurious quantities of soluble fluorides from drinking waters can be accomplished by dosing with alum with subsequent removal of the floc by sedimentation and filtration. Under certain conditions contact beds of activated alumina or some other aluminum compound that may be developed for this purpose may prove feasible. Household drinking supplies could be treated by shaking the water with activated alumina in suitable containers. The decanted waters would be clear. Softening with the addition of excess lime causes the coprecipitation of considerable fluoride. The extent of the above treatments will depend on the fluoride concentration in the raw water and the amount of fluorides which will ultimately be established as the toxic limit allowable in water supplies.

R. H. McKee and W. S. Johnston (*Indust. & Engin. Chem.* 26:849 [Aug.] 1934) report "the development of a method for removing fluorides from potable water by absorption by carbon. The process, however, has the handicap that at the time of treatment the water must be a pH of 3 or less."

The practicability of using any of these methods is dependent on the chemical characteristics of the water to be treated. It would be wise therefore before adopting any treatment process to seek the advice of a competent chemist.

TREATMENT OF SYPHILIS

To the Editor—A man aged 39 developed a tender swelling on the anterior aspect of the right tibia at the junction of the middle and lower thirds in September 1933. The swelling gradually became larger and was diagnosed as osteomyelitis. A surgeon everted the bone and inserted a pack. I saw the patient first in February 1934. At this time he was walking by means of a crutch and was unable to hear any weight on his leg. Although his history was entirely negative, a Kahn test showed his blood to be four plus in syphilis. Starting Feb. 17, 1934, he received weekly injections of nearsphenamine 0.6 Gm. for ten injections, after which he developed an exfoliative dermatitis. This cleared up on the administration of sodium thiosulfate intravenously daily for four doses of 1 Gm. each. The patient was immediately placed on weekly injections of iodobismutol. He was able to walk without crutches following his fourth injection of nearsphenamine. Iodobismutol injections were continued from April 1934 to December 1934 (thirty-two injections in all). The patient has been unable to take any form of arsphenamine immediately developing an exfoliative dermatitis from nearsphenamine, sulfarsphenamine and even 0.1 Gm. of bismuth arsphenamine sulfinate. The blood Kahn test has been steadily four plus since onset of treatment. A spinal Kahn test was negative when taken in February 1934 and was again negative in October 1935. Since December 1934 the patient has been on biweekly injections of sodium bismuth thioglycolate. The blood Kahn test October 10 was four plus. Thorough physical examination with emphasis on the cardiovascular system including roentgenograms is entirely negative. The patient feels well; he weighs 180 pounds (82 Kg.) and his leg has never bothered him since his fourth injection of nearsphenamine. For the last three months he has been on mixed treatment of mercury and potassium iodide orally with biweekly injections of sodium bismuth thioglycolate. Will you please tell me if you think it is possible for the patient to transmit syphilis? What further treatment should be used considering his intolerance to nearsphenamine? Do you think he is Wassermann fast or has he had inadequate treatment? Please omit name and address. MD West Virginia

ANSWER.—Resorting to the use of bismuth in this case has been good judgment as the patient's intolerance to the arsenicals has been well shown by his reactions to the various arsphenamine preparations used. Further efforts to give an arsenical of any type are contraindicated because the persistence of the positive serologic reaction in itself is not sufficient reason to jeopardize the patient's future by further injections of arsphenamine. The fact that the cardiovascular examination was negative for evidence of aortic disease and that repeated examinations of the spinal fluid have been negative places this patient in either the latent syphilis group or the Wassermann-fast osseous syphilis group.

The likelihood is that the disease is of more than three years duration, and with the treatment the patient has had thus far there is small chance that he is infectious. Further treatment should consist of repeated injections of the bismuth preparation, perhaps twelve injections to a course with intervals of three months between the courses. The bismuth treatment should be continued for the next three years. It is not infrequent to find a persistently positive Wassermann reaction in patients with osseous syphilis and the continued bismuth therapy alone will often revert the serologic reaction to negative sooner than will combined treatment with arsphenamine and bismuth compounds. At the same time the bismuth compound will maintain the patient in a noninfectious state. The treatment to date has perforce

been inadequate because of the patient's idiosyncrasy, and the continued use of bismuth compounds is the most potent means now at his physician's disposal to reverse the serologic reaction to negative.

NEUROSYPHILIS

To the Editor—A man aged 45 who first consulted me in September 1934 was awakened fourteen months ago by a severe pain in the left knee and in the tibia. It was a dull pain at first then a sharp severe pain which hits and fades. The skin is sensitive following relief from the pain. All but two attacks have come at night. The patient is sensitive to heat and cold. Heat causes pains in the eyeballs. He has heat and cold chills. Extra exercise results in an attack. There are dizziness and slight nausea. Examination showed fixed pupils. The patient is 5 feet 6 inches (168 cm.) tall and weighs 137 pounds (62 Kg.). The Wassermann and Kahn reactions of the blood are 4 plus under treatment; the blood remains the same. Treatment was as follows: In 1934 potassium iodide caused a reaction and had to be discontinued. Five doses of nearsphenamine 0.3, 0.3, 4.5, 0.6 and 4.5 Gm. and of tryparsamide 2 Gm. were given during October and November. Because of reactions from November 1934 to January 1935 weekly doses of mercurous 0.1 Gm., bismuth sodium tartrate 1.5 per cent or bismuth sodium tartrate and mercuric salicylate were given. Treatment was omitted from Jan. 23 to March 20, 1935. The Wassermann reaction was 4 plus, the weight 143 pounds (65 Kg.). From March to April the patient received six doses of nearsphenamine 0.6 Gm. and six doses of tryparsamide 2 Gm. During May a course of mercury and potassium iodide was given; there was too much reaction from the potassium iodide swelling of glands occurring. The patient was given 100 doses of yellow mercurous iodide; the same nervous reaction occurred to this. The patient rested in June. In July three doses each of nearsphenamine and tryparsamide were given. October, November and December 17, 0.1 Gm. of mercurous was given. The patient has rested since Jan. 17, 1936. He takes doses of phenobarbital when restless. He complains very little at present. Once in a while a slight pain occurs. He weighs 143 pounds (65 Kg.) now. He is feeling good and does his usual work. There is slight pupillary reaction. The Wassermann reaction is 4 plus. I am seeking information regarding the future course. Would the malaria reaction be indicated in this case? I will appreciate any information as to treatment and drugs best to use. This is probably a Wassermann fast case and I do not want to overtrear and certainly not undertreat. One item of interest that I failed to mention is that he had some thickening and discoloration of the palms of the hands. He thought it was the result of poison from varnish. It had been present for many years. This all cleared up under treatment. MD Iowa

ANSWER.—This patient probably has neurosyphilis, as evidenced by fixed pupils and the subjective symptoms. A spinal fluid examination would yield valuable information as to the type of central nervous system involvement that is present. In all probability the patient will remain Wassermann fast irrespective of the kind or amount of treatment used. If the spinal fluid is strongly positive, a course of fever therapy is indicated. If malaria is not available, the intravenous use of a typhoid-paratyphoid vaccine sufficient to give a febrile reaction of 103 or 104 F every third day might be considered. Fever therapy whether by malaria, vaccines or one of the newer fever producing machines should not be used without proper precautions under hospital supervision and only by those familiar with this type of therapy.

MANAGEMENT OF SYPHILIS

To the Editor—A woman aged 38 gives a history of having had syphilis for the past eleven years which she contracted from her first husband. She shows no signs of the disease clinically but has a positive Wassermann reaction. She states that she never had any symptoms or signs in the entire period with reference to the skin or mucous membranes. She has received treatment irregularly by different physicians in the past. She states that she could never tolerate arsenic preparations intravenously on account of vomiting spells following the injections. She was given preparations of bismuth and arsenic intramuscularly at various intervals. At present the only finding is a positive Wassermann reaction. What is the prognosis? Please omit name. MD New York

ANSWER.—With the information furnished it is difficult to answer. One would be in much better position to advise if one knew the results of the lumbar puncture and if one knew that cardiovascular syphilis had been ruled out. These are the two complications of late syphilis that are most damaging and yet which may remain hidden for some time. Therefore the patient should be examined from those two points of view at once. If nothing is found we would not be especially alarmed about the positive Wassermann reaction and would simply recommend a course of weekly injections of bismuth salicylate, a total of ten or twelve injections twice a year for possibly three years, giving potassium iodide between the courses of injections.

If involvement of these organs is found it would naturally require quite a different regimen and the advice would depend on the conditions discovered.

TREATMENT OF SYPHILIS

To the Editor—A well developed man aged 29 complained on his first visit of general weakness, lack of pep, and slight pains at times in the posterior urethra. Examination March 27, 1935, revealed slightly active reflexes, nervousness, irritability and a 4 plus Wassermann reaction. He has received fifty injections of nearsphenamine of 0.9 Gm each, fifty injections of bismuth sodium tartrate and potassium iodide regularly. Today he feels fine without complaints, and the Wassermann reaction is 4 plus. What would you suggest? Continue as I am doing, alter the treatment in some way or stop treatment altogether?

M D New Jersey

ANSWER—This patient has had an excessive amount of treatment without serologic improvement. Treatment should be stopped altogether for a time and then a spinal puncture should be done. If there is evidence of neurosyphilis, tryarsamide treatment is indicated and later on fever therapy. If the spinal fluid is negative and the blood serum still positive after the rest period, some other arsenical may be substituted, either arsphenamine or mapharsen, alternating with courses of another bismuth compound such as the salicylate. The treatment of a Wassermann fast case is discouraging but not hopeless.

PERSISTENT DERMATITIS

To the Editor—For eight years I have been troubled with an obstinate skin condition. While I was taking my premedical work I earned some money during the summers as a painter and decorator. It was while I was doing this that a vesicular condition appeared on the fingers of both hands. Soon there was a peeling of all the skin to the dermis causing weeping and considerable itching. In fact the itching was so intense that the rubbing and scratching I did made it worse. With the aid of ointments the condition improved somewhat. When I began the medical course it got worse, possibly because of the irritation caused by formaldehyde and phenol in which the cadavers were placed. I had the opportunity to get medical attention under a good allergy man. He tried many skin tests on me all proving to be negative. Several Wassermann and Kahn tests also proved negative. The allergist made an autogenous vaccine of some pustules that formed and gave me injections twice weekly over a period of more than four months without improvement. From that time there have been periods of improvement followed by a breaking down again of the skin of my fingers. As soon as I began my clinical work I made acquaintance with some of the best dermatologists in the country. With ointments and weekly x-ray treatment the condition cleared up nicely. I was tried on all sorts of ointments—sulfur, Whitfield's tar and so on. Tar (White's formula) seems to have been the best. The skin between my toes was examined and found to be in good condition. When I left school for my internship the skin on all my fingers was as normal in appearance as could be. The first winter during my internship caused my hands to become dry and chapped. The skin condition reappeared and has been with me ever since. This is a terrible handicap especially in surgical work. I know that water and soap do the skin no good but I have to wash my hands after treating infections. At present the skin over the affected areas is dry, thick and cracked. There are several vesicles, some of which are open and cause an oozing with resultant itching. There are no other lesions anywhere on my body. Please omit name.

M D New York.

ANSWER—The tops of the vesicles should be examined for ringworm fungi. If found, crude coal tar ointment or modified Whitfield ointment (3 per cent salicylic acid and 6 per cent benzoic acid in rose water ointment) alternated with soaks in 10 per cent solution of sodium thiosulfate, should be used. If no ringworm is present, the hands should be protected by the use of rubber gloves for pus dressings. On removing the gloves, one should bathe the hands in 50 per cent alcohol with 0.5 per cent salicylic acid and apply a lotion originated by William Allen Pusey:

| | Gm or Cc |
|----------------------|---------------|
| Liquid petrolatum | 16.0 |
| Oil of rose geranium | 0.1 |
| Oil of bergamot | 0.1 |
| Oil of lavender | 0.1 |
| Sodium benzoate | 0.5 |
| Powdered tragacanth | 2.0 |
| Mix and add water | to make 120.0 |

First shake up the oils and powders, coating the inside of the bottle. Then add the water, one fourth the amount each time, and shake vigorously. This makes a thick emulsion, a small amount of which should be rubbed into the hands after each washing. At times a liberal amount of it the excess being wiped off on a paper towel, may be substituted for washing. Use hot water as little as possible, always follow it, when used, with cold water and use the mildest obtainable soap. Each night anoint the hands liberally with 10 per cent boric acid in rose water ointment, petrolatum or equal parts of wool fat and petrolatum, wearing cotton gloves.

In the effort to raise the threshold of irritability, calcium lactate 4 Gm, with an equal amount of lactose, dissolved in half a glass of warm water, may be taken two times a day, dilute hydrochloric acid being taken after meals. Sodium thiosulfate, 1 Gm intravenously every other day, also may act favorably.

GLYCOSURIA OR DIABETES IN INFANT

To the Editor—A girl baby aged 8 months weighing 14 pounds (6.35 Kg) at present and 27 inches (68.5 cm) in length has been ill since the latter part of November 1935, when the mother noticed that the baby no longer ate well and that she was losing weight. The weight at that time was 14½ pounds (6.58 Kg). The infant was taken to the hospital for observation. She was a normal appearing and very active youngster and nothing abnormal was found except a trace of sugar in the urine. The anorexia persisted and also the loss of weight. The blood sugar was taken on two occasions and was 0.90 and 0.95. Three units of insulin was given twice daily with some resultant increase in appetite. The diet was chiefly solid food, junkets, pureed vegetables, orange and tomato juice, a total of 750 calories a day. Milk was taken from a glass as it had been since 4 months of age. Food was taken at three meals a day. The baby was given halibut liver oil, vitamin B and G syrup and orange juice. Gains were slow and uncertain. After three weeks the weight was only 14 pounds 9½ ounces (6.63 Kg). Physiologic solution of sodium chloride was given subcutaneously for three days, 120 cc daily and the weight went up to 15 pounds (6.8 Kg). She was discharged from the hospital still showing an occasional trace of sugar and eating well only with insulin. Now in the past two weeks since coming home the weight has steadily dropped and is now 14 pounds. She no longer takes adequate calories, possibly 500 daily and less than a pint of fluids daily, chiefly tomato juice. Insulin is being given in doses of 2 units three times daily. Can this be true diabetes? Is the babe on an adequate regimen? I would like suggestions as to treatment and prognosis. Please omit name.

M D Michigan

ANSWER—More information would be extremely helpful before a diagnosis of diabetes mellitus could be made in this case. The age of the infant would not preclude such a diagnosis, as the condition has been known to occur in infants under 1 year old. The chief symptoms, as stated in the history, are anorexia and loss of weight. Anorexia would be an uncommon symptom in diabetes mellitus. The trace of sugar in the urine requires further investigation. As a general rule the earlier the onset of diabetes, the more severe is the glycosuria. It is stated that the infant shows an occasional trace of sugar in the urine. It would be wise to ascertain whether the substance in the urine causing the reduction is actually a sugar. Occasionally lactosuria occurs, and differentiation of lactose and dextrose can be made by fermentation tests. Alimentary glycosuria, pentosuria and renal glycosuria might be nondiabetic causes for the traces of sugar in the urine. The blood sugar estimations, 90 and 95 mg per hundred cubic centimeters, are within range of normal (70 to 100 mg, average 90). Therefore no hyperglycemia has been demonstrated. A further investigation by means of sugar tolerance tests would seem indicated. A normal curve obtained by means of this test would rule out the diagnosis of diabetes mellitus. In a true diabetes, glycosuria and hyperglycemia are the essential phenomena. In the case under discussion there is a slight glycosuria and no hyperglycemia. Therefore, from the data presented, the diagnosis of true diabetes mellitus cannot be made. Other organic causes that might be responsible for the anorexia should be sought for and, if found, would determine the treatment and the prognosis.

TREATMENT OF FOOT INJURY

To the Editor—A man came to my office March 23 with a history of injury to the right foot about an hour before I saw him when he (a volunteer fireman) had been helping at a fire and a long ladder was dropped accidentally on his right foot. The skin was broken and the foot was sore at the point where the ladder struck. In my office there was found to be some swelling of the big toe and on the dorsum of the foot below the longitudinal arch, a fracture was palpated, the slight abrasion and place of injury were on the dorsal aspect of the foot at the distal end of the first metatarsal bone. Roentgenograms taken at once (anteroposterior and lateral) showed no fractures. Forty-eight hours after the injury there was only a little soreness and discomfort. Treatment consisted in elevation of the foot, no weight bearing and alternate hot and cold compresses. Since the roentgen examination of March 23 showed no fracture, no cast was put on the foot. I was not satisfied and so on March 27 I asked for another roentgenogram which revealed a greenstick fracture on the side of the cortex of the bone of the third and fourth metatarsal bones at the proximal end. There is no swelling or pain now. Is it now advisable to put on a cast? Our city carries no compensation insurance for such accidents. The city will pay the doctor's bill. My question is: Have I done enough to protect the patient, the city and incidentally myself? Please omit name and address.

M D Michigan

ANSWER—A metal arch support of german silver or of aluminum covered with leather should be carefully fitted to the foot and should be worn for at least six weeks. No weight should be borne on the foot unless the arch support is being worn.

If it is impossible to obtain such a metal support, a plaster-of-paris support can be molded under the arch and bandaged on or fitted in the shoe.

It is necessary to take these precautions to avoid a possible painful disturbance of the mechanics of the foot.

POLIOENCEPHALITIS WITH FACIAL PALSY

To the Editor—A girl aged 5 years became ill in November 1935 with what the parents thought was a severe cold. The child did not improve but developed also nausea vomiting and constipation. Examination disclosed the conjunctivae injected the nasal mucosa congested the throat mildly injected and facial paralysis on the left side, of supranuclear origin. Physical and neurologic examination was otherwise negative. She showed some improvement for three days and then became drowsy had some rigidity of the neck and all reflexes were increased. The temperature was 101 F. This phase lasted for five days. After the temperature fell a weakness of the flexors of the left foot developed lasted for four days and left no apparent residual. The facial paralysis persists and is a source of worry to the parents. It is most noticeable when the child is cold or when she smiles or grimaces. There is no apparent muscular atrophy. Treatment consists of gentle massage three times daily heat and potassium iodide. I have read the answer to the query on Bell's palsy in THE JOURNAL February 29 page 727. Will electrical stimulation benefit this patient? Would operation be advisable? Please omit name.

M D Indiana

ANSWER—The patient apparently has had a central lesion of an inflammatory nature and has probably a polioencephalitis.

Electrical stimulation will do but little good in this case, since the lesion is central. The length of time already elapsed without further improvement indicates that probably the maximum amount of recovery has already occurred. There is no available treatment for such a centrally induced facial palsy.

PASSIVE TRANSFER METHOD IN ALLERGY

To the Editor—The July 4 issue of THE JOURNAL on page 57 contained an answer to a question relative to the passive transfer method of testing in allergy work which interested me considerably. Apparently the inquiry was stimulated by my recent article which appeared in the *Cleveland Clinic Quarterly*. The method is of course used only as an adjunct to two other methods of allergy investigation. I have utilized the passive transfer method for complete tests in over 200 individuals the majority of whom were children. I believe that here it serves its greatest purpose and represents a distinct help in allergy investigation. The technique at the Cleveland Clinic has differed somewhat in the performance of such tests in comparison with that which you have outlined. We have not found it essential or advisable to dilute the serums as this would preclude clear cut reactions. We inject at least 0.3 cc. of the serum into each site for testing, and we do not consider 0.1 cc. as sufficient to sensitize the skin locally. If 30 cc. of blood is withdrawn from the patient to be tested there will be from thirty-two to forty-two sites. To ensure complete sensitization of the skin with the serum a period of forty-eight hours is required. On attempting to use the sites after twenty-four hours we have found the test results to be very unsatisfactory. We feel that only those sites which have not demonstrated any reaction can be used after the first tests have been made. On the occurrence of a definite reaction the reaction at the particular site has been exhausted and is not satisfactory for subsequent testing. We have found it preferable to wait forty-eight hours after the first set of tests are made to ensure complete absorption of the antigen from the site. To enable the physician to know the exact location of the serum a mark should be made at the site with a sharp scalpel owing to the fact that it is impossible to mark the skin in any other way to determine definitely where the serum has been placed.

I M HINKANT M.D. Cleveland

VASOMOTOR RHINITIS

To the Editor—In your reply to M.D. N.Y. re vasomotor rhinitis (THE JOURNAL August 15 p. 521) you state 'though injections of alcohol may be tried that method is not recommended.' A satisfactory experience with the alcohol injection extending over a period of seventeen years leads me to inquire why the method is not recommended.

In many cases the sensitization is local and whether the offending irritant reaches the sensitized cells of the nasal mucosa through the blood stream or directly by contact relief can be had only by avoidance of the irritant which is frequently impossible, or by desensitization of the tissues of the nasal cavities.

In the presence of a known allergin this may sometimes be accomplished by systemic treatment with injections of increasing doses of the specific provocative allergin if it is not too numerous and can be determined or by the desensitization locally of the nasal mucosa by the injection of alcohol combined with phenol or by the surface application of pure phenol to the nasal mucous membrane. The results of this method of treatment have been so gratifying that I have discarded the tedious expensive and unsatisfactory trial and error method of systemic desensitization.

While the alcohol phenol method sometimes needs repeating it seems frequently that the vicious circle is broken and the results are permanent. Many patients have gone from three to five years without a recurrence and should a repetition of the treatment be necessary it is such a simple matter as not to be considered an objection to its use.

A word as to the pain involved in the injection method. A local anesthetic soluble in the alcohol must be added to the mixture otherwise the pain is intolerable and seems not to be mitigated in the least by the preliminary use of cocaine or other local anesthetics.

Book Notices

Passive Vascular Exercises and the Conservative Management of Obliterative Arterial Diseases of the Extremities By Louis G Herrmann A B M D Assistant Professor of Surgery College of Medicine of the University of Cincinnati and the Cincinnati General Hospital With a foreword by Mont R Reid M D Cloth Price \$4 Pp 288 with 84 illustrations Philadelphia & London J B Lippincott Company 1936

This work describes one of the most interesting developments in the field of peripheral vascular disease, a treatment by rhythmic alternation of environmental air pressure In the introduction, general remarks are made concerning conservative treatment of obliterative vascular disease, the principles underlying passive vascular exercises nature's methods of developing collateral circulation, the importance of local hyperthermia, and the control of pain It is also pointed out that the vast majority of patients with obliterative arterial diseases of the extremities receive little or no active treatment until some complication such as infection or gangrene sets in There is a fascinating chapter on the historical development of the use of suction to improve arterial circulation in the extremities, with illustrations of these primitive and cumbersome machines, from which the present types of apparatus gradually developed This chapter represents a valuable contribution to the history of medicine Next the physiology of peripheral circulation and the physiologic effects of changes in environmental pressure and temperature are discussed This chapter is a clear easily understandable summary of present knowledge as applied to the therapy by suction and pressure One would like to see more direct evidence that the negative pressure actually sucks more blood into the treated extremity

In the fourth chapter the mechanism of collateral circulation and its spontaneous and therapeutic development are studied There follows an excellent description of the general management of peripheral vascular disease Due emphasis is laid on the fact that passive vascular exercise is only one link in the chain of therapeutic procedures which are all directed toward an adequate collateral arterial circulation

In the sixth chapter the basic mechanical principles of the passive vascular exercise apparatus, as developed for clinical purposes by Herrmann and Reid, are described The author modestly describes the development of the present apparatus but fails to mention the tremendous amount of thought and energy, trial and error devoted to the development of more and more efficient devices until the present product was obtained He then describes the technic of administering these treatments carefully going into minute details, enumerating the reasons for failure to obtain satisfactory results, and establishing criteria to determine improvement

In the eighth chapter the responses of various clinical entities to this form of treatment are discussed Finally the proper application of this mechanical device is stressed and a routine procedure used in the Peripheral Vascular Clinic of the University of Cincinnati for the study of such cases is described

While this monograph has been primarily written for the guidance of men who wish to employ the alternating suction and pressure therapy, it actually covers the entire diagnosis and treatment of obliterative peripheral vascular disease This is rightly so as nobody can suddenly understand peripheral vascular disease in all its aspects by simply becoming interested in an ingenious mechanical device Undoubtedly the greatest merit of this book is that it affords a wide dissemination of knowledge concerning peripheral circulatory disturbances This disease entity was previously recognized only in its terminal stages and treated by heroic and mutilating methods

Because of the rapid development within the last four years of this apparatus from large, cumbersome and technically incomplete devices to the newer, rugged, small, portable machines it is to be hoped that even more simple and equally efficient methods will be presented in the future so that an even larger number of patients may be benefited by passive vascular exercise The painstaking work and tireless energy that are represented in this monograph have already borne fruit all over the country They have made doctor and patient conscious of peripheral vascular disease.

Adult Intelligence A Psychological Study of Test Performances By Theodore Weisenburg M.D. Anne Roe Ph.D. and Katharine E. McBride Ph.D. Paper Price \$1.40 Pp 155 with 14 illustrations New York Commonwealth Fund London Oxford University Press 1936

The problem of exploring adult intelligence and characterizing it scientifically has been one that has confounded psychologists for years. The weakness of the standardized psychologic tests in investigating the intelligence levels and other capacities of adults has been one of the reasons why purely psychiatric and analytic procedures have been of more value to the clinician. The present volume makes no attempt to devise any new tests and, in a way, evades the determination of what constitutes an intelligent or an unintelligent adult. The problem of intelligence quotients and other expressions of the trait that are described as intelligence is not particularly emphasized. The tests that are used for giving intelligence quotients and mental ages are used only as part of the battery which these authors have compiled to deal with this problem. The reason for the present study lay in the approach which Dr. Weisenburg was making to the study of aphasia; the result of which study has previously been published and discussed in these columns, but Dr. Weisenburg and his associates were interested in finding out why some of the so-called aphasic reactions occurred frequently and in otherwise "normal" individuals. For that reason a number of tests of various sorts, intended to obtain a cross-section of adult test performances, were brought together and many interesting observations were obtained, which are reported in the present book. There is a good summary of earlier studies of intelligence tests of adults. The tests are described in another chapter and the distributions of the material in the samples are carefully tabulated and presented. One of the more interesting statements made is that sick persons in the hospital whose illnesses are not mental diseases (and who constitute the subjects in the present study) make excellent subjects for research on adult intelligence, most psychiatrists who are consultants to general hospitals would disagree with this. Any one with any experience with test material realizes that even a minor illness invalidates test results and that no amount of weighing can be made to obviate this factor. Nevertheless there seem to be some valid conclusions drawn in the present study and the evidence and careful study of the material that was obtained are well worthy of perusal by any one interested in the problem of examining adults intellectually. In their conclusions the authors point out the value of the various types of tests that they have used and it is noted that the vocabulary test, the analytic test and the absurdities test, as well as the educational tests, were most useful. It is also found that abilities sampled by tests requiring the use of language remain fairly constant through the thirties and that only a slight decline is noted thereafter. In other tests there were found marked declines in ability after the thirties. There are a number of gaps in the material presented by these authors which will need to be filled in later but, as in the case of Weisenburg and McBride's work on aphasia, the study shows extensive use of accepted statistical and experimental techniques and some fairly definite observations. There are good chapters on sex and age comparisons as related to the tests. Nevertheless this is not a book suited for merely cultural reading but rather a monograph to be used by those faced with the problem of understanding factors involved in the presence or lack of intelligence in the adult.

Practical Aspects of Psychoanalysis A Handbook for Prospective Patients and Their Advisors By Lawrence S. Kubie M.D. Cloth Price \$2 Pp 223 New York W. W. Norton & Company Inc. 1936

The present volume causes one to wonder whether the author is not rash. He seizes by the forelock the factors which have laid psychoanalysis open to the present-day criticisms and discusses them. He does not try to defend psychoanalysis as a technique or to explain the theory of the science but rather attempts to show its practical aspects in the way in which one would try to show practical aspects in medicine when guiding a patient to an appropriate specialist for his particular disorder. Psychoanalysts have developed codes of treatment of means of gaining admission to the field and of making financial arrangements that are peculiarly their own and cannot be compared to similar codes found in the medical profession as a whole. Nevertheless the volume explains well why it is

that psychoanalysis should be done only by those who are members of the psychoanalytic society of their particular community, why it is the patients have to make carefully thought out financial arrangements, and why the fees of psychoanalysts are so high. He discusses the attitude that the patient should take toward his treatment and toward his analyzer, and the attitude that should be taken by the family and by outside physicians toward this form of treatment. To those psychiatrists who have been admitted to the fold of psychoanalysis, the present volume will seem trite. To those who are outside the fold but are sympathetic some of the material will seem controversial and so much will be accepted as the psychiatrist's sympathy permits. But it is likely that to those who are not versed in psychoanalysis the tone of the book will seem to be commercial, somewhat unscientific and somewhat ecclesiastical. The volume probably will be of aid in clearing up certain arguments which the patient who is able to be analyzed will have in his mind and should at least to some extent resolve doubts which the critical layman will bring up, often severe, and which often have laid open psychoanalytic schools to considerable criticism. Stylistically it is not particularly profound, and it is slightly defensive.

Endocrinologie Par Noël Flegatnger médecin do l'Hôpital Ambroise Paré Collection des Initiations médicales publiée sous la direction du Dr A. Sézary Paper Price 20 francs Pp 152 with 19 illustrations Paris Masson & Cie 1935

This dissertation represents an attempt to present in very brief form the essentials of endocrine physiology, diagnosis and therapeutics. It is part of a series of treatises on practical medical subjects issued by the publishers, a forty page supplement to the present volume is devoted to advertisements of these and other books. About twenty-two pages are devoted to glandular physiology, a feat of compression that is a tribute to the author's courage but not to his erudition or critical judgment. The remainder of the work is concerned with endocrine dyscrasias, including a final chapter on therapy. One notes with apprehension the irrational character of many of the glandular products recommended by the author for clinical use.

Comparative Psychology A Comprehensive Treatise Vertebrates By Carl J. Warden Ph.D. Assistant Professor of Psychology Columbia University Thomas N. Jenkins Ph.D. Assistant Professor of Psychology New York University and Lucien H. Warner Ph.D. Research Associate Department of Zoology Pomona College Psychology Series Albert T. Poffenberger Ph.D. Editor Professor of Psychology Columbia University Cloth Price \$4.50 Pp 560 with 80 illustrations New York Ronald Press Company 1936

In a review covering the previous volume of this thorough work on comparative psychology it was pointed out that the material was systematically assembled and that the volume would be of great value to naturalists, general psychologists and possibly the psychiatrist who was interested in cultural matters closely allied to his own field. While the behavior of fishes, birds and reptiles, to which the present volume is devoted, probably has no direct bearing on the problems of psychologic medicine, there are types of behavior paralleling the human carefully studied here. The authors are planning to analyze, systematize and describe comparative psychology in three volumes. The first volume, on principles and methods has already appeared. The volume on plants and invertebrates should soon be in the hands of the public, and the present volume deals with the psychology of the vertebrates. In the same way in which biologists have recapitulated the history of the race in the fetal history of the individual, just so one can see in this study a recapitulation of behavior development through the various vertebrates until the behavior of the primate closely approaches that of the human infant. Each chapter is devoted to a single class and in the chapter one finds emphasis placed on receptivity, and locomotion and other reactive capacities. Whenever possible there is some discussion of inactive states modified behavior, and escape reactions and as the mental processes become more complicated there are cited numerous examples of such reactions as multiple choice delayed reaction reaction experiments, education of animals for service the use of tools and other interesting phenomena. The volume is well documented several thousand references being given. It should prove to be a valuable source book to the biologist and the physiologist. Its value to the general physician and even to the psychiatrist appears to be more obscure.

Ätiologie und Therapie der Varizen und des varikösen Symptomenkomplexes. Von Dr. med. habil. Felix Jaeger, Oberarzt der chirurgischen Universitätsklinik Berlin. Mit einem Geleitwort von Prof. Dr. Georg Magnus. Paper. Price 6.46 Mark. 1 p. 76 with 48 illustrations. Leipzig: Johann Ambrosius Barth 1936.

This is a small, clearly written pamphlet on the etiology and treatment of varicose veins and the varicose syndrome, based on the large material of the outpatient department of the surgical clinic in Berlin. There were about 1,500 such patients a year. The clinical picture is described, with excellent reproductions of photographs. Nothing is added to the well known theories about the causes of varicose veins except the emphasis on a hereditary weakness of the venous wall and the fact that valvular incompetence is only a secondary phenomenon. In the treatment the author advocates the use of salt and sugar solutions without preliminary ligation of the saphenous vein. A follow up of results showed 118 per cent recurrences and 218 per cent failures, leaving 664 per cent permanent cures. Even among this last group only 129 per cent had perfect results, whereas in 535 per cent the cosmetic result was poor, as the varices were palpable or visible as hard thrombosed cords. However, these patients were satisfied as their complaints were relieved. In spite of these modest results, the author does not advocate high venous ligation. In the last chapter some anatomic studies are presented which reveal the rather startling fact that the communicating veins and deep veins may also be affected by varicosities and that the involvement of the venules, especially above the inner malleolus, is responsible for the pigmentation, eczema and ulceration at this site. This presentation is an honest picture of the methods used and the results obtained in the Berlin surgical clinic. As such it may be recommended to men interested in the subject of varicose veins. It does not contain any new ideas or any indication of progress and sadly differs from past publications of this clinic.

Handbook of Physical Therapy. This Volume Contains Articles by Various Authors That Have Been Adopted and Authorized for Publication by the Council on Physical Therapy of the American Medical Association. Second edition. Cloth. Price \$2. Pp. 436 with illustrations. Chicago: American Medical Association 1936.

This handbook contains articles that have been accepted for publication by the Council on Physical Therapy of the American Medical Association. Several members of the Council have one or more articles in it. This is not a book for specialists—it is a handbook for the student, technician and general practitioner. The purpose is to acquaint the physician and surgeon with a therapy that will aid in arriving at a cure or relieving the disabled and uncomfortable patient. The field of physical therapy is covered in a concise manner, with necessary details given adequate exposition. There are sufficient illustrations, photographs and graphs to aid the reader. Charts, with the illustrative and legendary features carefully attended to afford excellent methods for teaching students and therapists. The chapter on body mechanics and posture is of definite merit. It presents the standard posture charts as well as methods of training in different age groups. All the chapters on physical agents and methods and their clinical application are presented in a scientific manner, revealing a strong adherence to facts and deductions from proper experimentation.

Fotografía del estómago. Sus aplicaciones en el diagnóstico del cáncer del estómago. Por el Dr. Herbert Hofmann. Paper. Pp. 127 with 104 illustrations. Buenos Aires: Aniceto Lopez Imp. 1936.

This monograph unfortunately does not present adequately the progress made in gastrophotography by such workers as Garin and Bernay of Lyons and Rehfuess of Philadelphia in the six years since the papers of Aschner and Ehrenthel (1930) and the books of Bécart and of Bernay (1931). The author has worked with Heilpern's gastrophotor, the results shown are so poor and unconvincing as to discourage every one. The well known 'lunar landscapes' are shown in numerous photographs but they obviously are not clear or intelligible pictures of either the normal or the pathologic mucous membrane. The discussion is not critical. The apparatus itself has been well described and a discussion of its optical capacity attempted. Presumably the author was not familiar with the critical literature comparing gastrophotography, gastroscopy and the x-ray relief technic, for if he were he would scarcely have published this

book. The difficulties of the optical system have not been surmounted as well in the instrument of Heilpern as they have in that of Garin and Bernay or the modifications of Rehfuess. The two main objections to gastrophotography, however, have not been mentioned by the author: namely (1) the impossibility of "aiming" the exposure and hence of knowing which part of the gastric mucosa is shown in the picture, and (2) the impossibility of obtaining films sensitive enough to bring out the slight differences in the color of the gastric mucosa, ranging as it does from yellow to orange red and red.

The Normal Diet and Healthful Living. By W. D. Sansum, M.D., Chief of the Staff of the Sansum Clinic, R. A. Hare, M.D., Member of the Staff of the Sansum Clinic, and Ruth Bowden, B.S., Dietitian of the Sansum Clinic, Santa Barbara, California. Cloth. Price \$2. Pp. 243. New York: Macmillan Company 1936.

Several years ago Dr. Sansum published a little book called "The Normal Diet," which proved to be one of the most successful of the popular treatises on the subject. It was succinct, sensible and understandable. That brochure has been expanded into the present volume and the same characteristics have been preserved. Most of the emphasis is placed on diet and its manipulation in the management of disorders of nutrition and the correlated functions of digestion and elimination—subjects in which Dr. Sansum has been interested and in the treatment of which his success is well known. Chapters on allergy, underweight and overweight, the care of the teeth and bacterial infection are new, as well as a chapter on a survey of methods of treatment which rapidly reviews the "many forms of treatment which have found acceptance in the practice of scientific medicine." The authors review these briefly in the hope that the reader will understand more of the care he may have under the physician of today. This chapter reviews briefly but ably rest, physical therapy, psychotherapy, drugs, vaccines, gland extracts, surgery, orthopedics and nursing. It is somewhat surprising to find no discussion of diabetes. Some of the opinions expressed are the following: Fatigue and the afternoon lag are associated with low blood sugar, and carbohydrate in quickly assimilable form will give relief. Pulpless teeth, even when they show no x-ray changes, are usually infected. The increase in obesity is due to the increase in the consumption of fats in this country. Food is our best source of vitamins, and if the diet is well balanced there is little need of using artificial products. The vitamin concentrates so frequently available today should be used only on the advice of a physician.

Röntgenographie Technique. A Manual for Physicists, Students and Technicians. By Darmon Atelle Rühnhart, A.M., M.D., F.A.C.B., Professor of Roentgenology and Applied Anatomy, School of Medicine, University of Arkansas. Second edition. Cloth. Price \$5.50. Pp. 431 with 183 illustrations. Philadelphia: Lea & Febiger 1936.

The new edition of this work affords an opportunity to make anew a favorable review of the successful effort of the author to provide a satisfactory textbook of roentgenographic technic. The technical procedures are fully described, having in mind the needs of x-ray technicians, medical students and classes of radiologic technic and those physicians who do some technical roentgenographic work for themselves. After a brief section on electric currents, x-ray machines, tubes and dark room equipment, there is listed a series of introductory experiments which it would be wise for every student of radiographic technic to follow through. Such experiments do more than any amount of reading to fix in mind the physical principles on which successful roentgenographic technic is based. The technic of roentgenography of the various anatomic divisions of the body is then taken up seriatim, with abundant text and numerous illustrations. The book is commendable for the purpose set forth in the author's foreword.

L'année thérapeutique. Médications et procédés nouveaux. Par A. Raylna. Dixième année 1935. Paper. Price 18 francs. Pp. 195. Paris: Masson & Cie 1936.

The 1935 French Year Book on Therapeutics is divided into two parts. Part 1 deals with progress in the treatment of diseases and symptoms. Part 2 takes up therapeutic methods and technics. It may be recommended to the physician who has a reading knowledge of French, as this annual naturally covers the current French literature better than the reviews published in other countries.

Creative America Its Resources for Social Security By Mary van Kleeck. Cloth Price \$3 Pp 353 New York Covici Friede 1936

American industrial history and current conditions are presented from the point of view of a conflict between "creative America" and the possessors of capitalized wealth. It is argued that the domination of the possessors is responsible for restricted production and the consequent poverty of the "creators," and that the removal of this domination and organization of industry, on the basis of scientific management, would provide plenty for all

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Radium Poisoning Liability of Employer — Irene La Porte was employed by the defendant radium corporation from May 1917 to December 1918 and for about six weeks in 1920 to paint numerals on watch dials with a luminous paint containing, among other ingredients, radium sulfate. She applied the paint with a camel's hair brush, which she pointed with her tongue and lips. In the latter part of 1927, approximately seven years after she left the employ of the defendant, she first suspected that she might have radium poisoning, but in the early part of 1928 her dentist and her physician assured her that she did not. In October 1930 she began to have pains in her legs and joints, and her condition was definitely diagnosed as radium necrosis. She died in June 1931, and an autopsy disclosed the cause of death to be osteogenic sarcoma of the pelvis due to radium poisoning. About a year later the plaintiff, as administrator of the estate of the deceased, sued the defendant to recover damages. When the defendant corporation pleaded the statute of limitations, the plaintiff instituted the present suit in the United States district court, D. New Jersey, to enjoin the defendant from pleading the statute, on the ground of equitable fraud.

There is no question, said the United States district court, but that dial painters, at the time the deceased worked in the defendant's factory, ingested and breathed radium sulfate. The dial painters were protected neither by special methods or devices nor by scientific ventilation. In the light of the knowledge of today it is tempting to create the thought that the defendant must have been negligent in some way. Today, industrial methods which the defendant then employed would not be merely negligent but criminal. But, observed the court, this case must be decided on the facts as they existed in the light of the knowledge of 1917 to 1920. The important factual question is to determine how much the scientific and medical world and the defendant then knew about the industry. Even today, the court said, problems concerning radium have hardly been touched. A decade and more ago theories presently accepted were in a stage of controversial experimentation or unknown. Several writers, as early as 1913, suggested that radium salts which were not eliminated from the body would eventually be deposited in the bone structure and there replace the calcium and actually become a part of the structure in the form of radium sulfate. This was theory and there were no computations at that time to indicate what percentage of a given amount of the soluble or insoluble salt taken internally would eventually reach the bone.

In 1917 many dangers to the human body from radium and radium emanation were recognized. Long exposure to emanation irradiation and x-rays had resulted, among a few technicians and scientific men, in fatal or dangerous injuries. But, the court observed the knowledge existing in 1920 concerning radium was so colored with conjecture and theory that it is now impossible impartially and reliably to rationalize it. The evidence was clear that the defendant was utterly ignorant of the harmful effects attendant on its factory process until 1924, when its attention was directed to an alleged case of radium necrosis suffered by one of its former employees. At that time it sponsored an investigation into the situation which developed

little information of value. Following this and other investigations, however, an article was published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (Dec 5, 1925, p 1769) entitled "Some Unrecognized Dangers in the Use and Handling of Radioactive Substances," by Dr Harrison S Martland. This article first established the occupational hazard in the dial painting industry.

Considering the matter in the light of knowledge existing in 1920, said the court, it is difficult to understand how the defendant can be said to have perpetrated a fraud when it, a commercial enterprise, failed to draw inferences which no physician had ventured, to the effect that its industry was suicidal to its workers. The court, therefore, felt constrained to find that in 1920 and up to 1924, in which time the two year period of limitations would have elapsed, there was neither knowledge of an occupational hazard in the dial painting industry nor, in the light of the knowledge concerning radium, reason for the defendant to believe or to have known of a hazard. The defendant could not have been under a duty to disclose a hazard which, so far as it or the world knew, did not exist. The court refused to enjoin the defendant from pleading the statute of limitations. —*La Porte v United States Radium Corporation*, 13 F Supp 263

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Improvement in Diagnosis of Whooping Cough—Gold and Bell report the results of the blood counts and determinations of the blood sedimentation rate in a series of proved cases of pertussis, they show the value and limitations of these laboratory procedures as aids in the diagnosis of atypical whooping cough, they discuss the difficulties encountered in the diagnosis of pertussis and review the literature, with especial reference to the diagnostic criteria in current use. A comparison of the usefulness of the various laboratory methods as an aid in early diagnosis of either the typical or the atypical forms of whooping cough suggests the following facts: 1. In the catarrhal stage (a) the cough plate-droplet method still remains indisputably the most successful approach, (b) the blood count proves to be too unreliable a basis on which to venture an interpretation of the leukocyte-lymphocyte formula, and (c) the sedimentation test is found to be misleading and, in the advent of retardation, becomes valueless through loss of its proper diagnostic significance in the absence of a characteristic blood count. 2. In the paroxysmal stage (a) cultures with cough plates are positive in only 67 per cent of the cases, while single tests are not always successful and require at least three days for results, (b) hematologic studies show that the expected typical lymphocytic reaction is present in approximately 80 per cent of the cases as the most presumptive evidence and (c) retardation of the sedimentation rate was demonstrated in at least 94 per cent of the cases in the series in which there was no complication, and it proved to be a valuable laboratory adjunct. 3. In the period of decline (a) cough plates are usually sterile, indicating the decreased contagiousness in this stage, (b) the sedimentation test possesses no special diagnostic importance in this late period, yet it may serve as a sensitive indicator of a complicating pathologic activity, and (c) the practical significance of the complement fixation test, the agglutination test and the cutaneous tests (included in the later half of the paroxysmal stage) is questionable.

Epinephrine Hydrochloride for Relief of Asthma—Graessner and Rowe show that the inhalation of epinephrine hydrochloride for relief of asthma is a practical and effective procedure in children of all ages and that success with this procedure is dependent on the use of a stronger solution than

is usually employed in the treatment of asthmatic symptoms, preferably 1:100, and an atomizer capable of delivering a fine vapor-like spray. This was accomplished by modifying the nebulizing mechanism of the common all glass atomizer. To prevent spilling of the solution into the mouth during use, an inverted moat was incorporated in the atomizer. This special feature was found desirable after several patients had complained of severe pain in the epigastrium, which resulted from the swallowing of small amounts of the solution accidentally spilled into the mouth. Such accidents cannot occur with the present atomizer. The method of using the atomizer is simple, but nevertheless it requires a modicum of coordination, which patients occasionally find difficult to acquire without considerable practice. Children aged 1 or 2 years cannot, of course, furnish the necessary cooperation to utilize the procedure. Children from 3 to 5 years of age may be trained to inhale properly and even to manipulate the atomizer themselves, but in general young children must use the mask apparatus designed to conform to the configuration of the face and to cover the nose and mouth. An atomizer of somewhat different external design than that previously described fits into the handle of the mask apparatus. A motor driven pump may be used instead of the hand-operated bulb to furnish air pressure for the mask. The authors say that, since the perfection of this method, they have used it as a routine for all patients. It is surprising how readily the younger patients learn to use the apparatus. The authors describe several case histories and conclude that the relief obtainable by this means is comparable, and in some respects superior, to the relief obtained with epinephrine hydrochloride administered hypodermically. The results obtained with inhalation therapy are superior to those obtained with all commonly used proprietary remedies.

- Vascular Changes in Intermittent Claudication. Note on Value of Arteriography in This Symptom Complex. J. R. Veal and Elizabeth M. McFetridge. New Orleans.—p. 113.

Effect of Ergotamine Tartrate on Nonmigrainous Headaches—Lennox and his collaborators administered ergotamine tartrate to forty-six patients suffering from nonmigrainous headaches associated with aseptic meningitis, intracranial pressure, subnormal intracranial pressure following removal of spinal fluid, postconvulsive headache, sinusitis, or artificially induced by means of histamine phosphate injected intravenously. Ergotamine tartrate was given to these patients in the same manner as to patients with migraine. 0.5 mg intravenously or subcutaneously. Besides the patient's statement of the effect on the pain, record was kept of the occurrence of nausea and vomiting, and of changes in blood pressure and pulse rate. The headache of these forty-six patients was relieved in 15, unchanged in 63 and worse in 22 per cent, as compared

with 89.8 and 3 per cent, respectively, of 120 cases of migraine headaches. Study of the results in the various conditions represented in the nonmigrainous group shows that, of the seven patients relieved, three were in the group of eleven headaches of unknown cause and three were in the group of eight post-convulsive headaches. The large proportion of epileptic patients who were relieved brings to mind the supposed underlying relationship of epilepsy and migraine, though more important may be the fact that postconvulsive headaches are naturally short lived. Of the ten subjects made worse by the injection, five belonged to this unknown group and two to the postseizure group. Not only is ergotamine of little account in stopping nonmigrainous headaches, but it may, according to Barger, imitate a headache. To test this point the authors administered the drug to thirty-eight subjects who were at the time free from pain in the head. Six of the subjects complained of resulting mild headache.

Abdominal Pain of Vascular Origin.—If, as Conner suggests, visceral arterial disease is analogous to coronary disease, Dunphy believes that the past histories of patients dying of mesenteric thrombosis ought to reveal evidence, in a certain percentage of cases, of chronic abdominal pain preceding the acute attack. With this point in mind he reviewed the histories of all patients dying of mesenteric vascular occlusion, confirmed by necropsy, in the Peter Bent Brigham Hospital. In seven of twelve cases in which the occlusion was associated with arteriosclerosis there was a story of chronic recurrent abdominal pain preceding the fatal attack by weeks, months or years. In all these cases mesenteric arteriosclerosis appeared to be the most plausible cause of the abdominal pain, but unfortunately in nearly every case varying degrees of coronary sclerosis rendered a convincing interpretation of the cause of the pain impossible. One case was selected as indisputable evidence of the occurrence of abdominal pain of vascular origin. An evaluation of the clinical and pathologic evidence in this case leads to the conclusion that a gradual occlusion of the mesenteric arterial system by progressive thrombosis was the cause of recurrent abdominal pain of a duration of two months. Although the pain was severe, it was not sharply localized, did not radiate and was not associated with muscular spasm or exquisite tenderness of the abdominal wall. In the beginning it was definitely related to the ingestion of food and only later became constant. On the basis of these characteristics the following hypothesis is submitted: Vascular pain in the abdomen is the result of an anoxemia of the intestinal wall and is a true visceral pain manifested through sensory neurons in the sympathetic nerves independently of the musculocutaneous pathways.

- Some Physical and Physiologic Properties of System Insulin Tannic Acid. F. Bischoff. Santa Barbara, Calif.—p. 239.

Suppression of Kidney Function After Exercise.—For their studies Hellebrandt and her associates had the cooperation of healthy young adult women students majoring in physical education and accustomed to vigorous exercise. It was found

that mild exercise has no influence on water diuresis. Urine formation after exercise is stimulated by moderate activity. More rigorous exertion associated with breathlessness and sweating inhibits diuresis during the period of work. Brief violent exercise, such as is accompanied by lactic acid acidosis and a large oxygen debt, suppresses kidney function for from forty-five to sixty minutes. There is a lag of forty-five minutes before the greatest excretory diminution occurs. When diuresis is resumed, the rate of urine formation may exceed that attained at rest. The prolonged arrest of diuresis after brief violent exercise cannot be attributed to failure in absorption. The hypothesis suggested is that kidney function is suppressed after violent exercise because (1) blood is depleted of water by virtue of the increase in concentration of osmotically active components in the muscles, (2) a prolonged negative phase in blood pressure ensues, and (3) a resultant disturbance in the balance of osmotic and hydrostatic pressures reduces the volume of glomerular filtrate until the cardiovascular and physiochemical disturbances of exercise subside, from forty-five to sixty minutes after the cessation of muscular work.

Metastases to Thyroid from Cancer of Colon.—Rankin and Fortune point out that their case of cancer is distinguished from an ordinary generalized carcinomatosis because of the occurrence of metastases in the thyroid. Cancer of the large intestine is less apt to produce distant metastases than neoplasms arising elsewhere in the gastro-intestinal tract. Further, carcinoma in the upper portion of the colon is less prone to distant spread than that occurring in the rectum. Mucin production in colonic tumors is of two types. In the first group there are many goblet cells and the mucoid change represents a differentiation of the carcinoma toward the normal function of colonic mucosa. These tumors are not prone to distant metastases and are among the less highly malignant of intestinal cancers. The

other group is highly undifferentiated and the mucin is present within highly atypical cells—the so called signet-ring cells. These tumors are highly malignant and are prone to metastasize early and widely. The mucin formation in this particular carcinoma is of the first mentioned type. The spread of this neoplasm has been by both hematogenous and lymphatic routes. The involvement of the thyroid is undoubtedly by way of the adjacent carcinomatous cervical lymph nodes. In spite of the proximity, however, such an occurrence is extremely rare. In carcinoma of the colon it is even less frequent and in the particular type of cancer (an annular carcinoma just proximal to the hepatic flexure) represented by this case it is most unusual.

Prophylactic Use of Anti-Gas Gangrene Serum.—In 1930 Lienthal began the systematic employment of local application of anti gas gangrene serum to the freshly incised thoracic wall immediately after operative evacuation of a putrid abscess of the lung. In nine operative cases of intrathoracic fetid suppurative disease and one case of true gas gangrene of the leg, there was not a single visible postoperative anaerobic infection of the muscles or skin. Having placed the drainage material into the abscess cavity, the author completes the dressing by packing the entire wound of the chest wall from the abscess to the surface with gauze saturated with the serum. This was placed in the form of a doughnut packing, leaving an opening for the deep drainage. At the early subsequent dressings this serum impregnated gauze was not disturbed and when at the end of five or six days the doughnut was no longer adherent to the chest wall it was removed, leaving a perfectly clean healing surface, with the areolar septums sealed. From now on the abscess was treated in the manner best suited to the individual case but in spite of the still present anaerobic organisms, no infection occurred in the chest wall. And even when other abscesses developed in the depths and were evacuated through the same opening, the fresh virulent infection from these hitherto undrained pockets did not infect the healing, granulating wound of the thoracic wall. No systemic effect ascribable to the serum such as serum sickness or urticaria, has been observed, and the danger of this complication may probably be disregarded because no intravenous or other injections are made. The price of the product is an objection but may be counteracted by reduction in the time and expense of hospitalization.

Hemiedema in Cases of Hemiplegia.—Luhan points out that marked edema localized to the paralyzed side in cases of hemiplegia arouses curiosity and stimulates inquiry concerning the mechanism of its causation, it particularly raises the question of the existence of cerebral vasomotor centers of contralateral dominion. After reviewing the literature on hemiedema he reports the histories of seven cases that he observed. After the first four cases had been encountered, a series of 100 patients with hemiplegia were selected at random and examined for the purpose of determining the gross frequency of vasomotor disturbances in cases of recent and of long-standing hemiplegia. In the conclusion the author states that hemiedema, or edema more marked on the paralyzed side, occurring at some time

during the course of hemiplegia was noted in fifteen of 100 unselected cases of hemiplegia. However, such edema is usually mild, marked edema of the paralyzed extremities rarely occurs. The edema itself is probably of cardiac or of renal origin. The cerebral lesion effects a tendency to localize actual or potential edema to the parietic extremities. There is clinical evidence to suggest that some of the circulatory disturbances in hemiplegic limbs may be of cerebral vasomotor origin, quite apart from the purely mechanical factors inseparably linked with the hemiparesis, but thus far the results of clinical studies, which were checked with postmortem observations, have not furnished any critical evidence for localizing a cerebral vasomotor center of contralateral dominion.

Subdural Traction and Posttraumatic Headache.—Penfield and Norcross point out that posttraumatic headache associated with dizziness is a clinical entity. They report the histories of cases in which treatment with cranial insufflation was carried out. They also describe experimental studies and outline two methods of therapeutic insufflation, namely, (1) a formerly described intraspinal method of insufflation and (2) a not previously described method of direct intracranial subdural insufflation. They say that the subdural space under normal circumstances contains a small body of fluid quite separate from the cerebrospinal fluid. Small movements that occur between the brain and the skull when the head is moved quickly are probably made possible because of this fluid bed. Such movements between the pia and the arachnoid are impossible because of the tissue septums that normally connect these membranes. The pathologic basis of true posttraumatic meningeal headache consists in an intimate adhesion of the arachnoid to the dura, which causes obliteration of the subdural space in a smaller or larger area. This does not mean dense adhesions, such as those of a scar. The sensitive area, which is likely to be affected by this adhesion, is usually a meningeal artery in the dura or, less frequently, a dural sinus. The chronic pain is due to pressure or traction on one of these sensitive areas because of the rotation in position of the brain produced by the blow and maintained by the adhesion. Effective therapy must provide for collapse of the ventricular system and the simultaneous introduction of air into the subdural space. As the head is oscillated the brain, which is shrunken because of the collapse of the ventricles, pulls away from the overlying dural covering with considerable traction, owing to its own weight. This separation accounts for the cure which results from proper insufflation of air. Failure may occur when this reopening is incomplete, and adhesion continues to stimulate a sensitive area of dura.

Operative Experience in Cases of Pineal Tumor.—Although an operative approach to the pineal region was proposed by Dandy in 1921, it was not until a decade later that the first pineal tumor was successfully extirpated. A disastrous

expense and annoyance toward pyelography. Cases of pyelitis or other urinary tract disease may be masked as essential hypertension and may continue to be unrecognized except in those few persons who develop infection or other acute urinary symptoms, thus directing attention to the urinary tract. Pain and frequency of urination in the female should not be dismissed so readily. Backache, pain in the legs, lassitude, listlessness and fatigue in the male should be subjected to a close scrutiny for prostatitis, vesiculitis and strictures. Diagnoses of "acid urine" and "strain" should be relegated to the prescientific era of medicine.

Bacteriophage Therapy of Chronic Furunculosis of Face—Gowen avers that the application of staphylococcus bacteriophage therapy to the face in cases of chronic furunculosis results in an exacerbation of the condition in from ten to twenty one days. Until this exacerbation occurs, clinical improvement does not take place. In cases responding well, clinical improvement seems to be associated with a disappearance of the aureus and citreus strains of staphylococci initially from the hands and secondarily from the face. When there is no diminution in the number of pigmented staphylococci there is no marked improvement, and bacteriophage therapy seems to be of no avail. When the skin flora is primarily sarcina, bacteriophage therapy has little, if any, effect on this type of flora and there is only a transient clinical improvement. There is evidence of an association between the ability of the skin to induce the S to R change and improvement. Bacteriophage therapy seems to stimulate rough colony formation to some degree. Because the flora of the face and that of the hands are similar, it would be logical to assume that the hands are continually playing a part in seeding new surfaces of the face and reseeding old surfaces.

Inclusion Bodies in Lead Poisoning—Blackman found intranuclear acidophilic inclusion bodies in the tubular epithelium of the kidneys and in liver cells in twenty-one cases of lead poisoning occurring in children, and similar inclusions were reproduced in the kidneys of guinea-pigs, mice and rats by adding lead to the diet of these animals. These inclusion bodies are variable in size and shape. Many of them are quite large and are round, smooth and homogeneous in appearance. Some are plastic and assume the shape of the distorted nuclei in which they occur. Some of the nuclei contain many small granular and droplike inclusion bodies. Like the intranuclear inclusions of virus diseases the majority are stained by dyes, such as eosin and phloxin, and they give a negative staining reaction for thymonucleic acid. It is probable that the inclusion bodies represent accumulations in damaged cells of the acidophilic material which is present in smaller amounts in normal cells. As in virus diseases, the nuclei in which the inclusions of lead poisoning occur are increased in size and altered in shape and the arrangement of basophilic chromatin

in the nuclei is also abnormal. The quantity of chromatin is greatly increased in some nuclei. In many others the chromatin granules collect along the periphery of the nucleus and also along the margin of the inclusion body, leaving a relatively clear space between the inclusion and nuclear membrane. The cytoplasm of the affected cells in the kidney especially is also damaged. Some cells are enlarged. Many are thin, flattened and basophilic in appearance. Some cells contain fat, especially in the liver, and in both kidney and liver completely necrotic cells are found. Evidence of regeneration of tissue in the kidneys is indicated by the presence of mitotic figures and cells with basophilic cytoplasm. The tubules in each cortical ray of the kidney are especially damaged by lead, and in this location atrophied tubules, scars and slight chronic inflammation may be found. In most of the affected human livers, aside from fat deposits in the cytoplasm and marked changes in the nuclei of the hepatic cells, there is slight inflammation and scarring in the periportal areas, accompanied in some instances by slight proliferation of bile ducts.

Temporary Recovery in Acute Aleukemic Myeloid Leukemia—Marcus reports a case of aleukemic myeloid leukemia, which at the outset appeared to be of an acute type. The patient made a complete recovery for from eight to ten months, with no evidence of the disease either on physical examination or on blood study and then again evidenced the symptoms of acute myeloid leukemia and died. The case is of further interest because of the following (1) a family history of having a brother suffering from Vaquez's disease and

a sister with Hodgkin's disease, (2) the axillary skin infiltration, which later disappeared, (3) the occurrence of vesicles on the skin containing serosanguineous fluid with induration about the vesicles, (4) the onset of the disease with manifestations of the joints strongly suggesting rheumatic fever, (5) only slight splenic enlargement at any time and (6) the comparatively large number of lymphocytes found at various stages throughout the disease.

High Sulfur Low Carbohydrate Diet in Chronic Arthritis—Forbes and his co-workers observed the effects of a high protein low carbohydrate diet on the clinical course of patients with chronic arthritis, together with studies of the accompanying changes in urinary indole. Definite improvement resulted in the majority of cases, the best results being obtained in patients with rheumatoid arthritis. Especially good results were obtained in young persons in the early stages of the disease. Coincident with improvement, the indoluria, which almost invariably accompanied the disease in its active stages, diminished and finally disappeared. It is suggested that indole is causally related to chronic arthritis and that diets rich in sulfur aid in the detoxification of indole with consequent clinical improvement in the condition.

Staining of Spirochetes and Related Organisms—In employing Gelaric's method, the material to be examined is smeared on the slide in a thin layer and allowed to dry in the air. It is covered with the zirconyl chloride solution (2.5 Gm of recrystallized zirconyl chloride dissolved in 100 cc of a 10 per cent solution of sodium chloride), allowed to stand five seconds and then washed with water. The zirconyl chloride solution acts as a fixative. Then a few drops of citric acid solution (a 10 per cent solution of recrystallized citric acid in distilled water to which a few crystals of thymol have been added) are placed on the smear, allowed to remain for ten seconds and washed off with water. A few drops of staining solution (0.25 Gm of gentian violet dissolved in 100 cc of tenth normal sodium lactate solution adjusted to a pH of 8.4) are placed on the slide, allowed to remain for thirty seconds and then washed off with water. This is followed by momentarily covering the smear with a few drops of mercuric iodide solution (0.5 Gm of mercuric iodide in 100 cc of 0.5 per cent potassium iodide solution) and again washed with water. Uniformly excellent results may be obtained by counterstaining with aqueous carbol methylene blue solution (0.2 Gm of methylene blue dissolved in 100 cc of distilled water with addition of 0.2 Gm of phenol) for five seconds. The dye is then washed off and the slide dried with filter paper. The specimen is examined by means of the oil immersion lens. In staining spirilla, the cell outlines are sharply defined and the integrity of the cell body is maintained. The red cells show a finely granular rose-colored cytoplasm, while the chromatin of the white cells stains blue. The spirilla are stained a deep purple (when artificial light is employed but when the source of light is daylight the organisms appear to be stained a deep blue, in contradistinction to the other elements present, which stain a light blue) differentiating them easily from surrounding tissue. *Spirochaeta pallida* is stained a deep purple and is very sharply defined in the clear colorless field or in the faint pink base formed by the stained coagulated serum. With spermatozoa to obtain exact detail counterstaining is not recommended owing to overstaining of the organism. The different parts head, neck and tail, with their components can be readily distinguished. The method can also be used for staining other micro-organisms such as gonococci and pneumococci. The mechanism of the method is explained on a chemico-physical basis.

Ocular Tularemia—The oculoglandular type of tularemia in which Pfingst is especially interested is not infrequent. Apparently it occurs in all parts of the United States. Last year he observed two cases of ocular tularemia, the first in his experience. The cases occurred in young men who had killed and skinned rabbits a few days prior to the ocular symptoms. Ten days later the diagnosis was verified by a positive agglutination test. The case ran a slow but acute course, the preauricular submaxillary and cervical glands suppurating and finally necessitating incision. Treatment consisted of washing the conjunctiva with antiseptic solutions, hot cloths to the enlarged glands and the use of 15 cc. of antitularemia serum (Foshay) intravenously on successive days for two doses. Complete recovery without sequel took place in five months. When the patient was last examined the agglutination test was still positive. The disease usually involves both eyes. Typical cases present multiple discrete ulcers of the palpebral conjunctiva with indurated margins. The disease is associated with swelling and marked injection of the conjunctiva of the lids and considerable chemosis. The preauricular glands and later

the lymphatic glands under the angle of the jaw nearly always become enlarged and tender and often abscessed. There is considerable discharge of mucus, as a rule. Constitutional symptoms, chill, fever and depression prevail as in other types of the disease. The disease closely resembles Parinaud's conjunctivitis and leptothrix conjunctivitis (Verhoeff). The clinical features aid in differentiation, but the positive diagnostic sign in ocular tularemia is the agglutination of *Bacterium tularense* in the blood of a tularemia patient. Most cases of ocular tularemia terminate in spontaneous recovery in several months and leave no sequels, although a small percentage of cases have terminated fatally by way of a general bacteremia.

Rales in Determination of Arrest of Tuberculosis—Proffitt asserts that there has been a tendency on the part of many physicians, if the other conditions are met, to disregard the presence of rales in the lungs, even in the upper lobes, in the diagnosis of arrested tuberculosis. And they have apparently laid little stress on the type of rales in these cases. From his personal observation of many tuberculous patients and a recent review of several hundred case files, it has become apparent that the disregard of rales in the lungs, when making the diagnosis of arrested tuberculosis, has been ill advised in a proportion of cases. Moist rales in the upper lobes, such as are typically found in active pulmonary tuberculosis, are of the utmost importance, and only in rare instances should a diagnosis of arrested tuberculosis be made while they are present. In view of the most accepted theories concerning the anatomic and pathologic structures giving rise to rales, it would seem logical to assume that rales and activity might be divorced but experience teaches the close relation between the two, and until other criteria of a more reliable nature are formulated, one may do well to give due respect to the medium rale.

An Antidiuretic Hypophyseal Hormone—Gilman and Goodman base their conclusion, that the antidiuretic substance found in the urine has its origin in the posterior pituitary gland and is probably identical in nature to the pharmacologic preparations derived from that gland, on the following evidence: 1 Hypophysectomized rats, dehydrated to the point of death (forty hours), fail to secrete this antidiuretic substance in their urine. Control rats under identical experimental conditions always show appreciable amounts. 2 Both the antidiuretic substance of the urine and solutions of posterior pituitary of the same antidiuretic strength are destroyed to the same degree by thirty-minute hydrolysis with 1 per cent hydrochloric acid, thirty-minute hydrolysis with sodium hydroxide and thirty-minute reduction with one tenth normal sodium bisulfate. 3 The molecular size of both the antidiuretic substance extracted from the pituitary and that excreted by the kidney is such that no appreciable loss in activity results from a three hour dialysis with a cellophane membrane with a wall thickness of 0.00072 inches. The authors interpret these experiments as strong evidence that (1) an antidiuretic substance is secreted by the posterior pituitary, (2) this substance is a true hormone, passes into the circulation and acts on the kidney, (3) the pituitary hormone in its circulation through the kidney filters through the glomerulus and escapes into the urine, in which it is relatively stable and easily detectable, (4) the need for water conservation by the body is a stimulus for the secretion of this hormone.

Meningitis Serosa Circumscripta Spinalis—Elkington analyzes the clinical and operative observations of forty-one cases of spinal circumscribed serous meningitis. While the pathogenesis is often obscure it is suggested that trauma, meningeal infections and syphilis are among the causes. The essential change is the development of adhesions and cysts in the spinal subarachnoid space, which produce secondary intramedullary changes by compression and ischemia. The symptoms and signs closely resemble those of spinal compression by tumor, but certain points of value in the differential diagnosis are noticed. The disease is predominantly one of middle age, and a history of definite spinal trauma, of past infection of the subarachnoid space or of syphilis is of value. Though the more common mode of onset is that of an insidious spinal compression, the commencement with spontaneous pain, when it occurs is highly suggestive. Examination of the cerebrospinal fluid does not serve to distinguish the condition from spinal compression due to other causes. The diagnosis can be suspected but not established before operation. The prognosis must be regarded as grave but is least so in those cases in which operation is performed early before irreversible changes have occurred in the cord itself.

Progressive Dementia Due to Tumors of Third Ventricle—In his presentation of two cases of tumor of the third ventricle, Riddoch pays little attention to focal symptomatology but stresses the occurrence of progressive dementia in absence of severe headache, of vomiting and of either papilledema or optic atrophy. Gross hydrocephalus was present in both cases and was, it is believed, the cause of the mental deterioration. Progressive dementia, without headache and papilledema, may occasionally result from invasion of both frontal lobes and the anterior part of the corpus callosum by an infiltrating glioma or a centrally placed meningioma but the dissociation and its duration are again dependent on the rate of development of the pathologic process. When ventricular blockage is very slow and progressive but variable the process extending over a period of months or years as in the present cases, headache, vomiting and papilledema may be absent even at a stage when dementia or stupor general enfeeblement and incontinence are advanced. The severity of these symptoms indicates the degree of reduction of general cerebral function from slow compression. That great improvement may follow relief from compression by removal of its cause is in favor of the view that impairment of blood supply is the primary factor. In the causation of headache, gross variation in tension in the vessels, especially the arteries and venous sinuses and dural septums probably plays an important part. Few hypothalamic symptoms were present, which is not surprising as the floor of the third ventricle was not directly involved by the growth in either case. Polyuria and polydipsia adiposity or loss of weight were absent. In one case transient glycosuria occurred with the first attack of unconsciousness twelve years before, and in the other case excessive sweating and mild fever were present throughout the observed part of the illness. Abnormal drowsiness so common with lesions in this region was a prominent feature in both

cases. That the anterior part of the midbrain was affected in each case was shown by the pupillary abnormalities, including reflex iridoplegia. But since the lethargy appears from the first to have been associated with mental dulness, it is safer to assume that it was a general rather than a focal symptom.

Artificial Opsonization of Bacteria—Gordon and Thompson have followed up and extended the work of Reimer and of Neufeld. In addition to tannic acid and the various salts studied by the previous workers a large range of other substances has been tested for opsonic action on the staphylococcus. This range includes many vegetable tannins, salts of chromium, iron, aluminum, lead, zinc, copper, magnesium, calcium, barium, cadmium, nickel and cobalt, and also gallic, acetic, lactic and sulfuric acids, trinitrophenol, formaldehyde and catechin. A definite parallelism has been found between tanning action and opsonic activity and it is considered that the irreversible chemical changes characteristic of tanning are responsible for the changes in physical properties which make phagocytosis possible. Dehydration is an invariable consequence of tanning action, but the authors do not consider it to be the primary factor. The substances that show opsonic activity almost always possess agglutinating power—a property which a tannin would be expected to show on theoretical grounds.

Relation Between Conjunctivitis and Trachoma—MacCallan enumerates the various forms of conjunctivitis which on occasion may bear some resemblance to trachoma. He divides them into (1) common conditions (follicular conjunctivitis in children, acute conjunctivitis with follicles and chronic conjunctivitis with corneal vascularization of former interstitial keratitis or former phlyctenular ulceration), (2) uncommon conditions (spring catarrh, toxic follicular conjunctivitis, Parinaud's conjunctivitis, swimming bath conjunctivitis with inclusions, conjunctivitis with inclusions not of swimming bath origin, nongonococcal conjunctivitis with inclusions in infants and follicular type of tuberculous conjunctivitis or syphilitic conjunctivitis), (3) rare conditions (actinomycosis, sporotrichosis).

chosis squirrel plague conjunctivitis and bilateral lymphoid infiltration of the conjunctiva) and (4) tropical conditions (trachoma dubium and chronic gonococcal conjunctivitis). In the absence of infiltration of the normally clear cornea by a cellular exudate, and of the vascularization characteristic of trachoma, conjunctivitis may be determined to be nontrachomatous. In many cases of follicular trachoma, stage 1, the appearance of the follicles and their position at each extremity of the retrolarsal fold of the upper lid is characteristic. However, no such characteristic appearance obtains in trachoma when there are no obvious follicles, but merely a widespread subepithelial infiltration which makes the conjunctiva red and velvety.

Epidemic Nausea and Vomiting—Miller and Raven state that in March 1936 there occurred in an English boarding school an epidemic which presented some novel features and resembled the widespread epidemics recently reported in Denmark under the title of "epidemic nausea." Its symptoms consisted either of vomiting of sudden onset or of nausea, to which was added in a fourth of the cases the sensation of giddiness, sometimes of considerable severity. The illness ran a short afebrile course, all the patients, with one exception, being fully restored to health within forty-eight hours, yet in spite of its apparent mildness the epidemic attacked within a period of fifteen days no less than one half of the pupils and one third of the adults in the school. Altogether among 117 residents there were fifty-two cases, this total including four pupils who became ill at their own homes within a week of leaving the school. Considered primarily a disease of the alimentary system, it becomes difficult to account for the symptom of giddiness, absence of fever, the suddenness of the onset of the vomiting and the absence of diarrhea in the English cases. The English epidemic resembles one originated by some form of food contamination; the heavy incidence of cases in the first two days of the outbreak suggests this although the same phenomenon may be seen in epidemic poliomyelitis, which all do not yet admit may be due to infected food. In this connection the only type of gastro-intestinal infection which seems to be worth considering is a possible gastric type of Sonne dysentery. Regarded as a possible infection of the central nervous system, such a hypothesis is favored by the suddenness of the onset of vomiting, the occurrence of giddiness and the absence of fever, but it is impossible to hazard any opinion on the type of infection of the nervous system that could be responsible for the epidemics.

Ophthalmoscopic Signs of Death—According to Salisbury and Melvin, definite changes easily visible with the ophthalmoscope, appear in the retina in the dead or dying. In

life the actual movement of the column of blood is visible in the retinal veins. As death approaches the stream seems to become slightly irregular and "lumpy" although without any actual breach of continuity. Later there is definite fragmentation of the column, and these masses of blood can be seen to move (like marching men) toward the optic disk and then drop over the edge of the optic cup. This is not a transitory effect. Although no actual timing has been attempted, one would estimate that the movement is visible for about ten to twelve minutes on an average. During this time two changes gradually occur. The rate of motion becomes progressively less and the fragmentation progressively more definite. It is as though the marching columns of men, at first in close formation and without organization, gradually formed into companies, with definite intervals between them. These intervals become greater as the rate decreases. After all movement has ceased the interrupted columns are still plainly visible. So long as the mediums remain transparent there is no difficulty in differentiating this appearance from the former or from the normal appearance during life.

Infection and Infantile Cirrhosis—Lahiri investigated the etiology of twenty-five consecutive cases presenting clinical features of infantile cirrhosis of the liver. The health of the mothers in most of the cases was bad. Gross dietetic errors were noticed in only a small number of cases, but a history of irregular feeding was present in all. The total count was generally between 10,000 and 20,000 per cubic millimeter. There were small mononuclear counts, generally from 44 to 60 per cent, polymorphonuclears from 22 to 47 per cent. In one case enlargement of the liver was noticed several days after the onset of fever a fact also noticed by Ghosh (1887) in some of his cases. In other cases the liver was already enlarged and hard when first examined. The spleen was enlarged in sixteen cases. Enlargement occurred after the fever had continued for some time, and always after the enlargement of the liver. The quantity of the urine was normal or slightly less. There was no difficulty in micturition in any of the cases. The reaction of the urine was acid in all cases. While the presence of bacilli in the urine is not pathognomonic of infection, the signs and symptoms, such as fever enlargement of the spleen along with the enlargement of the liver, leukocytosis febrile reactions to autovaccine (prepared from urine and blood culture) and ultimate recovery from the disease by vaccine injections in some cases point to infection being an important etiologic factor. The presence of hemolytic streptococci in the blood of one of the patients also favors the same view. Though in most of the cases the presence of bacilli could be demon-

strated in the urine, symptoms of bladder or renal disease were virtually absent. In the presence of other evidence of infection this may be taken to mean that the real site of infection was not the urinary tract but elsewhere in the body, the bacilli being simply excreted through the kidneys. The conspicuous hepatic features of the cases point to the liver as being the chief site of infection. Slow pyrexia closely resembled that generally seen in many cases of infantile cirrhosis of the liver. It can be concluded that in many cases presenting typical clinical features of infantile cirrhosis of the liver infection plays an important etiologic part. In order that an infection may gain a foothold in an organ with such an extraordinary vitality as the liver has, it is necessary, though not absolutely essential, that it should be previously deranged by long continued dietetic errors or by some other devitalizing factors.

Treatment of Puerperal Infections—Colebrook and Kenny treated thirty-eight cases of puerperal fever infected by hemolytic streptococci with oral and intravenous or intramuscular doses of the hydrochloride of 2,4-diaminoazobenzene-4'-sulfonamide (prontosil). Subject to confirmation by further experience, the impression has been gained that in many of the more severe cases the drug has exerted a definitely beneficial effect, manifested by an unexpectedly prompt fall of temperature and remission of symptoms, and supported by a substantial reduction in mortality. Three patients in whom there was a generalizing peritonitis on admission recovered without laparotomy under large doses of the drug. The clinical results, together with the mouse-protection experiments, support the view that further clinical trial is amply justified and that there is more hope of controlling these streptococcal infections by the early administration of this or some related chemotherapeutic agent than by any other means at present available. While the drug has been well tolerated by most of the patients, there have been transient toxic effects in some and many have shown indications of a mildly irritant effect on the tissues of the urinary tract. Three developed sulfhemoglobinemia. At present there is no indication from animal experiments that the drug is likely to have a beneficial effect on puerperal infections by organisms other than the hemolytic streptococci, and in view of the toxic effects referred to its administration should be confined to such cases. Apart from the fact that the growth of the streptococcus is somewhat retarded (although not suppressed) in the serum of patients under treatment little is known as to the nature of its antimicrobial influence in the animal body. The invasive character of the streptococcus seems to be unchanged by contact with the drug or the serum of treated animals. There is no evidence of any "immune response" being evoked by it.

Protection Against Experimental Infections—Buttle and his co-workers found that *p*-aminobenzenesulfonamide will protect mice against streptococcal infection. It has the same therapeutic activity as hydrochloride of 2,4-diaminoazobenzene-4'-sulfonamide but is less toxic when given orally so that it is possible to obtain better protection by giving larger doses.

Protection can be obtained against streptococci belonging to different serologic types. Some protection of mice against meningococcal infection has been demonstrated, but it has not been possible to demonstrate protection against staphylococci or pneumococci. Increase in the number of sulfonamide groups attached to the benzene nucleus to three is accompanied not by increase but by extinction of the streptococcidal activity. The anilide of sulfanilic acid is as active as the amide. Sulfanilic acid itself has a smaller, but not negligible, protective action. Azo compounds derived from *p*-aminobenzenesulfonamide and phenolic cinchona alkaloids are inferior to hydrochloride of 2,4-diaminoazobenzene-4'-sulfonamide, in this respect.

Serious State After Suboccipital Puncture in Patient with Cerebral Tumor M. Pinard and Temerson —p 951

Physiopathology of Pulmonary Embolisms—Villaret and his collaborators studied the question of how and in what manner a clot situated in a pulmonary artery can induce death. The physiologic problem of clinical accidents following pulmonary embolism can be summed up in the following question: How can the pulmonary aggression caused by the embolus act on the whole organism? There are two theoretical answers to this question: 1. The pulmonary embolus can affect directly the respiratory and circulatory functions of the lung. 2. The embolus once arrived in the lung can cause general accidents of reflex nature. A long study of the physiopathology showed the authors that neither of these explanations is exact but that each, depending on the individual case, contains a certain amount of truth. They carried out experimental studies on dogs and obtained large emboli by means of large pearls of enamel without lead. To obtain a certain and regular pulmonary embolism it was necessary to use the external right jugular vein for the introduction of the pearls. Mucilaginous grains in aqueous suspension also were effective. In order to obtain small emboli they injected powdered stone. The effects of large emboli were studied in more than fifty dogs. The first conclusion of the work was that it was practically impossible to cause death in a few minutes or even in several hours even by means of voluminous emboli in dogs. They were impressed by the slowness of the effect of the emboli on the respiratory rhythm. The production of small emboli was found to effect extraordinarily little change in dogs. The surprising contrast between the size of the embolus and the importance of the dyspneic phenomena that resulted in dogs was the most noteworthy result of the experiments. The authors therefore believe that sudden death can only be the result of a reflex determined by the embolizing particles on the nervous terminals of the pulmonary arterioles.

Prevention of Accidents Following Pulmonary Embolism—Villaret and his collaborators think that anatomical facts show that there is no constant relationship between the size of the embolic obstruction of a pulmonary artery and the severity of the clinical phenomena that are produced. Physiologic investigations have confirmed the idea that sudden death can be the result only of an inhibiting reflex and that it does not depend ordinarily on the mechanical prevention of the blood flow in the lung. Furthermore anatomical investigations have demonstrated the essential part of pulmonary vasomotor phenomena caused by embolism. The postembolic pulmonary infarct follows the same mechanism as apoplexy of nonembolic origin. In investigations using rabbits and dogs it was found that once a dog has received ephedrine, atropine and sodium bicarbonate rapid death can no longer be produced with a volume of embolism identical with one that would previously have caused death. On the contrary acidosis obtained by intravenous injection of a solution of hydrochloric acid causes the embolism to become much more rapidly fatal. Alkalosis

the other hand, produced by intravenous injection of a solution of sodium bicarbonate, causes the embolism to become fatal much more slowly. Thus both neurovegetative factors and humoral factors become important modifiers of the reaction to embolism in dogs and rabbits.

Air Cysts of Lung in Staphylococcal Septicemia—

Pruvost and his co workers describe the case of a man, aged 26 whose disease appeared to develop in four successive and distinct phases. The first was characterized by septicemia alone to which the prognosis was attached. The secondary lung alterations, even though they changed the clinical appearance of the disease, did not change the prognosis. In the course of the second stage there was no longer septicemia either clinical or bacteriologic, and it was then possible to make an etiologic diagnosis of a pulmonary suppuration of staphylococcal origin. In the course of the third phase of the disease the lung changes produced no fever or effect on the general septicemia, the phase of uncomplicated cyst. The fourth period was characterized by a generalized pneumothorax with a large cavity and was the phase of balloon cyst or ruptured cyst. Thus in one patient successive phenomena characteristic of cysts namely, infectious phenomena followed by mechanical ones, were observed. The suppuration of the cyst dominated the clinical history in the course of the first stage of the disease and the increase in size of the cyst and its rupture dominated the succeeding phases.

Physiopathologic Study of Cerebral Hemorrhage—

Paulian and Bistriceano believe that it is possible that extravasation of blood causes compression necrosis not only of the peripheral cerebral tissue but also of the veins and arteries. They investigated this possibility in two cases. In one case, histologic examination revealed a double cerebral hemorrhage, an old one affecting the right lenticulostriate region and the more recent one the opposite side in the same area. The hemorrhage followed a rupture of the lenticulostriate arterioles as a result of cerebrovascular sclerosis. In the other case necropsy revealed a voluminous hemorrhagic area the size of a mandarin occupying the superior portion of the left parietal lobe. The hemorrhagic area penetrated deeply into the centrum ovale of the region and compressed the central nuclei of the left side. There was no connection between the ventricular cavities. Microscopic examination of sections at the level of the hemorrhagic area showed hard masses of blood surrounded by a fibrous capsule. In certain regions the masses of erythrocytes were delimited by a large zone of migratory cells of neuroglial or leukocytic origin and an abundant infiltration of old hemorrhagic granulations. In the more peripheral area was a manifest gliofibrillary reaction, and an abundant invasion of blood pigment was noted. The vessels were dilated and filled with red blood cells. The veins also showed in certain regions hyperplastic walls and sometimes torn walls with an abundant leukocytic infiltration. The authors therefore believe that arterial hemorrhage can thus by compression produce changes in the neighborhood of the veins which are similar to the peripheral lesions caused by the original hemorrhage.

Schweizerische medizinische Wochenschrift, Basel

66: 657-676 (July 11) 1936 Partial Index

*Experiments on Significance of Waves in Electrocardiogram W Knoll—p 657

*Balneotherapy in Venous Thromboses T Schaeppi—p 659

Masked Gout, C J Finck—p 660

Treatment of Ganglions, M Saegesser—p 663

Significance of Waves in Electrocardiogram—Knoll points out that for a while it seemed that it had been definitely established that the QRS complex, together with the after

fluctuation, the T wave, indicated the ventricular systole, whereas the subsequent not deflected line up to the beginning of the P wave supposedly corresponded to the ventricular diastole. However, others advanced a different interpretation. The author was induced to reinvestigate this problem by observations he made on work electrocardiograms of thoroughly trained sportsmen. During work that was accomplished with the legs, the leads were taken from the arms in order to determine in what manner and how rapidly the electrocardiogram would change under the influence of the exertion of work. It was found that at the onset of work usually after one or two cardiac contractions, characteristic elevations and other changes appeared in the T waves whereas the QRS complex was hardly at all changed. If the QRS complex corresponded actually to the ventricular systole, it was difficult to comprehend why, particularly in the event of greater exertion no changes would be manifest in this part of the electrocardiogram, whereas the T waves, the after fluctuations, showed such great changes. In order to gain a better insight into this problem, the author devised a method of experimentation which would permit the simultaneous recording of the mechanical processes on the heart and of the electrocardiographic curve in such a manner that the two could be compared. The author decided on the cinematographic photography of the heart and on electrocardiography by means of Siemens' transportable tension electrocardiograph. His experiments were made on a dog and later on a monkey (hamadryad). The author describes the recording, shows reproductions of some of the records he obtained and compares his method with similar ones recently described in the literature. He admits that contraction is a mechanical process while electrocardiography is an electrical one, and that for this reason a direct comparison is impossible. However, investigations conducted by de Jong demonstrated that the two processes follow each other rapidly and may even concur. The author points out further that between the state of dilatation of a muscle fiber and its tendency to contract there is a connection in that the stimulus for contraction is dependent on the state of tension. Consequently he sees in the concurrence of the QRS complex with the diastole that condition which is the basis for the subsequent contraction. To be sure, he admits that this is only a possibility for which there is as yet no definite proof. In his cinematographic records, the ventricular contraction goes from the base to the apex and there are also slight time differences between the two sides of the heart. Moreover, since there is no real period of rest, Schellong's opinion gains in probability, namely, that during life there coexist always irritable and nonirritable muscle fibers, that is, those which are ready to contract and those which are not, contracted and dilated ones.

Baths in Treatment of Venous Thromboses—Schaeppi calls attention to a type of bath that is helpful in the treatment of varicose veins and of venous thrombosis and which can be given in private homes. Into a full bath (approximately 150 liters) of a temperature of 37 or 38 C, a salt mixture is placed consisting of 500 Gm of sodium bicarbonate and 100 Gm of alum. The patient remains in this bath for twenty or thirty minutes a day, but care must be taken that the temperature remains approximately the same (by adding more hot water). The total number depends on the type and severity of the disorder. As a rule, from twenty to twenty-five baths are sufficient. In case of phlebitides and of venous thrombosis, he recommends a preliminary treatment with leeches, but, if the phlebitis is superficial, the baths can be begun five or six days later. For the deep thromboses he recommends an interval of three or four weeks. The latter patients are carefully lifted into and out of the bath in order to prevent embolism. The swelling of the legs and feet commences to disappear as a rule after six or eight baths. The curative period of the severe thromboses, which otherwise may extend over several months, can be considerably reduced by the bicarbonate-alum baths. The same can be said about the superficial phlebitides. In simple varicose veins, the efficacy of the baths is not quite so convincing. The author admits that a protracted warm bath itself produces a hyperemia of the skin, however, control experiments with indifferent baths prove that they do not have the same effect as the bicarbonate-alum baths.

- *Hypophysis in Experimental Tuberculosis M Mosco—p 83
Sclerosing Chronic Tuberculosis of Adrenals with Compensatory Hypertrophy C Pana—p 86
Value of Tuberculin Skin Reaction in Adults A D'Arienzo—p 91

Hypophysis in Experimental Tuberculosis—Mosco performed histologic studies of the hypophysis of a lot of forty guinea-pigs with experimental tuberculosis of a chronic and attenuated type. The changes in the hypophysis consisted in the presence of congestion and hemorrhage in the anterior, posterior or both lobes, proliferation of glial and connective cells of the posterior lobe, in which granulomatous tissues existed only in rare cases, nonfollicular granulomatous infiltration of the anterior lobe and degeneration of the nucleus and protoplasm of the cells of the anterior lobe at the sites where there was no granulomatous infiltration. Giant cells, tubercles and tubercle bacilli were not found. The author believes that the histologic changes of the hypophysis in the animals of his experiment resulted from the effects of tuberculosis at a distance rather than locally. The results of the experiment confirm the part played by tuberculosis in the pathogenesis of hypophyseal syndromes.

- *Progressive Muscular Dystrophy Treatment by Pancreatic Extracts G Meldolesi—p 1187
Appendicocoele Case A Breccia—p 1200

The Treatment of Progressive Muscular Dystrophy—Meldolesi reports satisfactory results from the administration of total pancreatic extract in large doses, by mouth in forty-eight patients suffering from progressive muscular dystrophies of several clinical varieties and of different intensity. The extract is administered until the processes of digestion, especially tryptic digestion, become normal. In all cases further development of the condition is controlled in about six months. The results depend on the possibility of reversibility and compensation of the pancreatic and muscular alterations that are characteristic of the disease. In cases in which treatment is given early in the development of the disease the establishment of atrophic and retracting phenomena is prevented and the activity of the muscles returns to normal by hypertrophy of the muscles not as yet involved in the pathologic process. In cases of moderate evolution in which pancreatic lesions have taken place and there is more or less muscular retraction the static and motor functions greatly improve, especially if the necessary orthopedic and surgical corrections are made. In grave cases in which the static and motor capacities are greatly impaired, the treatment fails to give practical results but improves the movement and general condition of the patient. In certain cases the muscular and general improvement of the patients is surprisingly good even in desperate cases.

Temporary Sterilization of Women by Injections of Semen—Baskin's technic (*Am J Obst & Gynec* 24 892 [Dec.] 1932, abstr *THE JOURNAL*, April 22 1933 p 1286) is as follows. After intercourse in which a condom is used the semen is brought to the office as soon as possible. One cubic centimeter of a 1 per cent hexylresorcinol solution is added the entire amount is drawn into a syringe and an intraglutal injection is performed. No semen is used with a count of less than 80 000 000 spermatozoa per cubic centimeter. Three injections are given at seven day intervals. The amount of semen injected each time varies from 2 to 5 cc. From his experience with a group of twenty-one women Escuder concludes that

success depends on careful technic. Sterility lasts for twelve or fifteen months. The injections are harmless to women. Injections of sperm cause no grave local reactions or endocrine disturbances. The method of sterility is especially indicated in tuberculous women in whom pregnancy is contraindicated.

- *Toxic Disturbances Following Intravenous Injections of Calcium. A Alvarez Fernandez—p 1
Psychopedagogic Study and Treatment of Abnormal and Delinquent Children F Fierres Perez—p 4

Toxic Disturbances Following Injection of Calcium—Alvarez Fernandez reports three cases of pulmonary tuberculosis in which the appearance of toxic symptoms (chills, fever, diarrhea, vomiting, vertigo, disturbances of respiration, intense warm appearance of pallor and asthenia), following the intravenous injections of calcium gluconate and lactate, respectively, made it necessary to discontinue the calcium treatment. The solutions used in the injections vary in concentration between 5 and 10 per cent. Patients treated by intravenous injections of calcium chloride or calcium thiosulfate did not develop toxic symptoms even if 10 per cent solutions of calcium chloride or thiosulfate were administered. However, the administration of intravenous injections of calcium chloride or calcium thiosulfate to two patients suffering from tuberculous hemoptysis resulted in the production of hemoptysis following the injection and in disappearance of the former on discontinuation of the latter. The author is skeptical of the results of the calcium treatment in hemoptysis and believes that hemoptotic cases can be included in the group of cases in which the administration of calcium chloride results in the production of toxic disturbances.

- Intra Uterine Impairment of Fetus H Naujoks—p 1039
*Menstrual Cycle of Three Weeks Duration H Futh—p 1044
*Some Electrocardiographic Aspects of So-Called Nervous Heart E Ekey—p 1051
Chronic Relapsing Icterus R. Meissner—p 1053
Thoughts on Evaluation of Patients with Nervous Disorders A Werner—p 1054
*Diet for Children with Fever Liselotte Meyer—p 1057

Pregnancy and the Twenty-One Day Menstrual Cycle—Futh says that Wahl's report (abstracted in *THE JOURNAL*, April 18, 1936, p 1432) induced him to study the duration of gestation in women who have a menstrual cycle of three weeks. He says that in women with a menstrual cycle of twenty-one days or less the birth of a mature infant can be expected before the 280 day term in 78 per cent of the cases. Only a small percentage of these women give birth after 280 days, and about 16 per cent bear the fetus longer than 280 days. Of the latter infants, about 12 per cent are hypermature at birth, whereas according to Zangemeister, excessive size is observed in only 7 per cent of the total number of past term infants, that is in women with a short menstrual cycle it is approximately twice as frequent as is ordinarily the case. In view of these facts the author concludes that the practitioner has to be careful in computing the date of delivery for women with a menstrual cycle of three weeks and that for instance permission to travel should not be given toward the end of the gestation, since confinement may take place before the normal term.

Electrocardiographic Aspects of So-Called Nervous Heart—Ekey describes a number of cases with cardiac symptoms in which the ordinary examination disclosed no pathologic changes in the heart and which for that reason were at first diagnosed as nervous heart. Electrocardiography, however, disclosed organic cardiac defects and the author concludes that electrocardiographic examination should always be made in cases of so-called nervous heart.

Diet for Children with Fever—The diet recommended by Meyer for children with fever is practically free from protein. It furnishes large quantities of fluid in the form of sweetened tea and fruit juices. Nurslings are given in addition to these fluids one raw egg yolk, and older children are given some steamed fruit and toast and later also two raw egg yolks. Depend-

on the duration of the fever, the diet is continued for from two to eight days or even for twelve days. This form of diet is usually well liked by the children and also well tolerated. The diet supplies the great fluid requirements of the organism during fever, it is readily assimilated (carbohydrates, chiefly sugar) and furnishes an adequate amount of calories. Rapid passage through the stomach prevents vomiting and the absence of protein is advantageous, particularly in cases in which the kidney and the liver are impaired. The intake of large amounts of lipoids and vitamins improves the general condition and the defense powers of the organism.

- Ray Treatment of Sarcomas Particularly of Bone Sarcomas Grashey, Glauner and Meese—p. 234

Treatment of Sciatica—Altschul says that in the treatment of sciatica he obtained favorable results with a combination of roentgen irradiation of the region of the root and of the course of the nerve and of injections of radium chloride into the region of the root. The roentgen rays are applied in doses of 200 roentgens to each of the fields (one over the root and one or two over the painful regions). After an interval of two weeks, the injection treatment is begun. Six injections (one each day) are made into the region of the root. At the first three injections 1 millicurie is given, at the last three 2 millicuries. Two weeks later, another series of roentgen irradiations are applied. This combination therapy has produced favorable results, but in some cases either of the methods alone produced lasting results.

Roentgen Treatment of Coccygodynia—According to Baastrup, the term coccygodynia is applied to various disorders that have only the localization of the pain in common. The best defined entity is the traumatic form, which is most frequent after deliveries, particularly in primiparas. Some of the traumatic cases are caused by a fall on the coccyx (skating, falling downstairs or other accidents). Coccygodynia may be elicited also by tumors, tuberculosis, osteomyelitis, rheumatism, uterine disorders, hemorrhoids and fistulas. The symptoms of coccygodynia are difficulty in sitting down and getting up from the sitting position, pain during defecation, particularly when there is constipation, and local pain and sensitivity of the coccyx. In discussing the treatment, the author says that hydrotherapy, diathermy, heat treatments, baths, faradization, antineuralgics and protein therapy have been recommended for the traumatic forms, if these measures fail, the surgical removal of the coccyx is indicated. The operation counteracts the pain but involves considerable dangers (osteomyelitis of the sacrum, fistulas, infections). Moreover, the operation is usually a failure in the nontraumatic forms. The hydrotherapeutic and other expectant measures likewise fail often to produce the desired results. The author decided to try roentgen treatment in an extremely severe case which had proved refractory to several other treatments. He applied 300 roentgens, using a filter of 5 mm of aluminum. The pain decreased until it had practically disappeared. At the appearance of mild signs of release, two more doses of 150 roentgens each and later a dose of 200 and a dose of 300 roentgens were applied, all of them with good results, the patient being now free from symptoms. The author describes fifteen other cases of coccygodynia (seven traumatic and eight of other origin) in which he resorted to roentgen therapy. He usually applied 300 roentgens but tried different filters and intensities. In some of the patients, other treatments had been tried without success. Ten of the fifteen patients are practically well now. One other patient, who is well now, was operated on for hemorrhoids so that it is difficult to say whether the operation or the roentgen rays effected the cure. One patient could not be found in the follow up inquiry, one was only temporarily improved and the roentgen treatment was without effect in

two. The author considers roentgen treatment justified in men (provided the testes are covered) and in women who are past the age of the menopause.

Treatment of Radiodermatitides—Bordier discusses the dermatitides and their malignant complications that occur in workers with roentgen and radium rays or after treatment with these rays. He points out that numerous antiseptic preparations were tried but failed. The results of the remedies that were intended to influence the nutrition likewise failed to come up to expectations. Brocker suggested the use of infra-red rays and obtained favorable effects with these rays in two cases of ray dermatitis. The author, however, prefers diathermy, calling attention to the favorable effect exerted by the high frequency currents on the trophic disturbances in the tissues. If the ray dermatitis is in a region in which the tissues consist largely of fat (abdomen) and the circulation of the humors is deficient and vitality of the tissues is impaired, the treatment must aim at increasing the vitality by stimulating the circulation of blood and lymph fluid in the region of the ulceration. Diathermy exerts a hyperemic action not only in the region of the ulceration but also in the tissues underneath. A lead electrode is applied 3 or 4 cm from the edge of the ulcer. A second electrode is applied on the other side of the ulcer so that the high frequency current passes through the tissues under the ulcer. The treatments are applied in series of twelve or fifteen sessions. The intervals between the sessions differ from case to case, but the interval between the series does not exceed a month. For the ray dermatitides that develop in tissues that have little fat (face, hand, leg and so on), the author recommends coagulation by diathermy, the aim being to destroy the tissues that have been injured by the rays. Following the coagulation he applies gauze compresses saturated with 1 per cent phenol. The bandages are changed daily. For the ray dermatitides that assume a malignant character, the author likewise recommends coagulation by diathermy. He employed it for twenty-five radiologists who suffered from malignant degeneration of keratotic fields. He cites passages from some of the reports written by the radiologists themselves.

Changes in Hypophysis During Beriberi—The observation that the pressor principle of the hypophysis counteracted the vascular symptoms of beriberi induced Marburg and Wenckebach to investigate whether the vascular defects of patients with beriberi might not be caused by a dysfunction of the intermediate and posterior lobes of the hypophysis and particularly by that of their basophil cells. The authors made their studies on the hypophyses of Chinese workers. They found that degeneration and atrophy of the basophil elements, chiefly of the smaller ones, was the most common and the most noteworthy change. They admit that histologic pictures do not permit conclusions regarding the gradual development of a process, nor do these histologic aspects indicate whether the changes of the hypophysis were primary or produced by disorders of other organs. Nevertheless, they think that these changes exerted some influence on the symptoms of beriberi. This is the more probable since the changes in the adrenals and the tuber cinereum, which might be of importance in beriberi were virtually irrelevant.

Glutamic Acid as Substitute for Salt—Mainzer directs attention to his first report on glutamic acid as a substitute for sodium chloride (abstracted in THE JOURNAL, June 20, 1936 p. 2205) and, in view of the fact that the glutamic acid is eliminated partly as urea, he now describes his studies on the

relations between the concentration of urea and chlorides in the urine. He made tolerance tests with urea and sodium chloride, alone or together, on normal persons and on those with renal diseases. Moreover, in some of the tests he replaced the urea by glutamic acid. It was found that there is an antagonism between the concentration of the nitrogens and the chlorides in the urine. This antagonism differs only quantitatively in normal persons and in those with renal disease. A mathematical analysis of the problem makes it seem probable that the antagonism in the concentration is due to an osmotic antagonism between urea and chloride. The greater the renal insufficiency, the greater also the practical importance of this antagonism in the concentration.

*Connections Between Zoster and Varicella K. Kundratitz—p. 788

Syphilis-like Roentgenologic Aspects in Skeletal Diseases—Epstein and Klein describe eight cases of nonsyphilitic bone diseases in which the roentgenologic aspects greatly resembled the various stages of syphilitic skeletal disorders. All except one of these cases were of a septic pyemic nature and showed involvement of the joints. They appeared, like the syphilitic bone diseases, on the epiphyseal ends, even on those that were far removed from the focus of the disease. This permits the assumption that, in the growth zones of the bones and in the adjoining diaphyseal portions, there were in addition to the clinically recognizable foci also changes that resulted from toxic or bacterial influences. In spite of the apparently severe nature of the changes, retrogression set in, and in the majority of cases the pathologic changes disappeared entirely under the authors' observation. In this disappearance too they resembled the syphilitic bone diseases. The patients observed by the authors were children who were in the first year of life, that is, the bone disorders developed at the same time at which the syphilitic changes usually appear. From this it is concluded that the skeleton has a certain predisposition for such disorders at this time of life. The authors stress the importance of these observations for the differential diagnosis of skeletal disorders during early childhood. On the other hand, they show that even the roentgenologic examination of the bones does not always permit an etiologic diagnosis during the first few months of life.

Relation Between Zoster and Varicella.—Kundratitz reviews the epidemiologic and clinical factors that were cited in earlier reports in support of an etiologic relationship between zoster and varicella but says that there are still some investigators who, in spite of this evidence, reject a connection between the two conditions. He then cites cases of his own observation which indicate an epidemiologic relationship between zoster and varicella and reports studies he conducted on the immunizing action of zoster against varicella. Other factors which he considers indicative of a common etiology of zoster and varicella are the identical cytologic aspects of the zoster and varicella blisters as well as the identical morphologic and staining characteristics of the elementary bodies in the vesicular contents of new zoster and varicella efflorescences which also show crossed agglutination. The author admits that the complement fixation reaction gives contradictory results, but he thinks that with a certain technique the results would be more uniform. He points out that it has not been determined as yet why in some cases the symptomatology of zoster and in others that of varicella develops. Some have assumed that the virus may appear as a neurotropic mutation or as a dermatotropic one. Another explanation is that differences in the

infected persons might be responsible for the differences in manifestation. In this connection the author points out that varicella occurs frequently in children, or at the age when acute exanthems are most frequent, whereas zoster occurs chiefly in adults, who are more subject to diseases of the nervous system. These varying reactions to the same virus would corroborate Pirquet's theory of different allergic reactions during the various age groups. Other observers have expressed the opinion that the development of zoster could be explained as the result of a cutaneous immunity, which had been acquired by adults either through an attack of varicella or by so-called silent infection. The author concludes that it can no longer be doubted that zoster and varicella are etiologically related, for outside of the virus of varicella no other virus has as yet been demonstrated in cases of zoster, and assumptions of the existence of a different virus are merely unproved hypotheses.

*Theophylline with Ethylene Diamine and Its Application in Therapy
T. Geil—p. 677

Theophylline with Ethylene Diamine and Its Application in Therapy—Geil asserts that coronary disturbances (sclerosis or thrombosis) and complications present the main field for the use of theophylline with ethylene diamine and discusses the marked therapeutic value of this agent in cardiac asthma and Cheyne-Stokes respiration. He reports a case of coronary thrombosis with violent precordial pain, in which large doses of morphine were ineffective but intravenous injections of theophylline with ethylene diamine immediately allayed the pain. In a patient with grave syphilitic disorder of the aorta and heart given massive doses of digitalis the injection of theophylline with ethylene diamine was followed by a typical digitalis bigeminy. The effect of theophylline with ethylene diamine as a diuretic apparently does not surpass that of other purine derivatives.

Celiac Disease Studies on Hypovitaminosis A I. C. Friderichsen
—p. 689
Pathogenesis of Infectious Toxic Encephalopathy J. V. Jørgensen
—p. 699

Resorption of Vitamin A in Celiac Disease—By determining the weakest light irritation that can cause an oculomotor reflex, Friderichsen obtains the quantitative expression of the degree of hypovitaminosis A in infants. In a case of celiac disease in an infant with fairly grave hypovitaminosis A revealed by this method, vitamin A in sweet milk, mashed carrots and spinach and a concentrated vitamin were not resorbed. After administration of mother's milk the reflex irritability of the eye against light rapidly became normal and the characteristic changes seen in hypovitaminosis (pale and yellowish complexion, dry and scaly skin, pigmentation, brittle hair, keratosis on the plantae) disappeared. Because of the reduced resorption of vitamin A in celiac disease the author suggests that the disease may be a manifestation of a disorder of the reticulo endothelial system.

DELIVERY AND CARE OF THE NEW- BORN INFANT OF THE DIA- BETIC MOTHER

LAWRENCE M RANDALL, M D
AND
EDWARD H RYNEARSON, M D
ROCHESTER, MINN

Priscilla White¹ recently has written a most comprehensive article on the problems which arise when a diabetic woman becomes pregnant. It is not our purpose to reconsider this entire subject but rather to offer suggestions for one of its phases, namely, the delivery and care of the new-born infant.

Prior to the discovery of insulin, pregnancy for the diabetic woman was particularly dangerous. Fortunately, then, the fertility of diabetic women was low and few of them conceived, a high percentage of those who did conceive died, as did most of the infants. Since the discovery of insulin the situation has changed. Many of those who have diabetes in childhood now live to reproduce. The fertility of women who have diabetes that has been controlled is higher than was that of diabetic women before insulin was discovered, in addition, diabetes now can be better controlled during pregnancy, so that more infants come to the period of viability. This does not mean that diabetes complicated by pregnancy is no longer a problem, on the contrary, new problems have arisen, chiefly those of reducing fetal mortality. There has been a gratifying decrease in maternal morbidity and mortality.

Prepartum, intrapartum and postpartum deaths of infants of diabetic mothers have maintained a high rate. Priscilla White stated the problem well when she said "Prevention of the death and decay of the over-ripe fetus of the diabetic mother is a challenge today to the obstetrician and research worker in the field of diabetes."

The approach to this problem first involves the consideration of the time and mode of delivery, and, secondly, the postpartum care of the child. In considering the time and mode of delivery it should be emphasized that the obstetrician is not dealing with a normal woman. No matter how well the diabetes is controlled there are too many abnormal factors involved to permit of a casual decision. The usual conceptions of pregnancy are no longer correct when the expectant mother is diabetic. A diabetic woman who becomes pregnant is an abnormal woman who requires special care and consideration. Every effort should be made to keep her condition satisfactory, not only for her

sake but because there is an additional life at stake—a life which is in much greater danger than the mother's. As previously mentioned, we believe we know enough about diabetes to prevent the mother's death from that cause, but the important question is how and when should she be delivered to give the baby the best chance? In all probability the baby is going to be large, for 60 per cent of such babies weigh more than 8 pounds (3.6 Kg.), as compared to 9 per cent of babies of normal mothers. This means a more difficult labor if the mother is allowed to go to term. The fact that the baby is large does not mean that it will be healthy, on the contrary, it may be "flabby" and born dead. The incidence of stillbirth in cases in which the mother is diabetic is many times that occurring in normal deliveries. Not only is the child likely to be injured by the difficulties of labor but it often succumbs in utero to the abnormal state existing in the last few weeks of pregnancy. If the child can be spared this abnormal state which culminates in the stress and strain of normal delivery, its chances for life are materially increased. For this reason we advocate delivery by cesarean section in the thirty-sixth or thirty-seventh week of pregnancy, at which time sterilization can be accomplished if permitted and advisable. We agree with White, who said "Premature delivery of the fully developed, though chronologically premature infant of the diabetic mother by cesarean section is the obstetrician's successful answer to the challenge."

What are the immediate dangers confronting this new-born child and how can they be met? Particularly during the third trimester of pregnancy the pancreas of the infant has been attempting to supply the insulin the mother lacked. After birth the child's pancreas continues to overfunction and produces hypoglycemia.

There is ample evidence to support this statement. In 1915 Carlson and Ginsburg² removed the pancreas from pregnant bitches that were almost at term and found that diabetes failed to develop in the bitch until after delivery but occurred soon after. This indicated that the fetal pancreas supplied the needed insulin for the diabetic bitch. Bower and Heilbrun³ reviewed the subsequent efforts to prove and disprove this conclusion. Pack and Barber⁴ offered strong support and also answered those critics who doubted the permeability of the pancreas to hormonal transmission, when they injected insulin into the fetuses of goats and produced a decrease in the maternal blood sugar. reversed this procedure when he injected insulin into a pregnant cat and studied the fetal blood sugar. He found a decrease in the kitten's blood sugar, which rapidly returned to normal.

The amount of sugar in the blood of normal mothers and infants was studied by Morriss,⁶ who found the average value for the mothers' blood sugar to be 135 mg per hundred cubic centimeters and that for the infants' blood sugar to be 115 mg per hundred cubic centimeters. Rowley⁷ found normal values for blood sugar of the mothers and no significant changes in the amount of sugar in the blood obtained from the umbilical cords. Revesz and Turolt⁸ found that the value for the sugar in the blood of the umbilical artery was 10.33 per cent lower than for the sugar in the blood of the umbilical vein, the value for the maternal blood sugar was higher than either. The amount of sugar in the mother's blood increased during labor. Schretter and Nevinny⁹ and Popova¹⁰ found that the value for the normal infant's blood sugar may be low for several days following birth. This unquestionably is related to the activity of the infant's pancreas. Holzbach¹¹ found insulin in the pancreas of normal fetuses of all ages, including one fetus that weighed but 21.5 Gm. He also reported a case of diabetes¹² in which the value for the mother's blood sugar increased from 120 to 210 mg per hundred cubic centimeters within a few hours following the intra-uterine death of her child.

Dubreuil and Anderodias¹³ first reported the finding of hypertrophy and hyperplasia of the islands of Langerhans in a fetus of a diabetic mother. Not only were the islands present in large number but they were from thirty to forty times the usual size. This far exceeds the figures of normal fetal island cells as given by Nakamura,¹⁴ who found that the fetal islands were about four times the size of those found among adults but reported none so large as those found in the fetuses of diabetic mothers. Wiener,¹⁵ Gray and Feemster,¹⁶ Holzbach,¹⁷ Lawrence,¹⁸ Nevinny and Schretter,¹⁹ Schretter and Nevinny,²⁰ Sennewald,²¹ Stepp,²² Ehrlich,²³

Gordon²⁴ and Higgons²⁵ all have reported cases in which the islands were large and numerous. In cases in which the value for the blood sugar was determined, it was found that the value for the fetal blood sugar was much lower than that for the maternal blood sugar, the former often was so low as to produce the symptoms of hypoglycemia.

There is no doubt that hypoglycemia explains many of the deaths of infants born to diabetic mothers, although in his review Skipper²⁶ said "The occurrence of fatal hypoglycemia in the child after delivery has not been proved."

In an effort to treat this condition, Wilder and Parsons²⁷ in 1928 suggested that the infants should be fed immediately after birth. Sennewald successfully treated an infant who had hypoglycemia by administering a solution of dextrose by rectum. Higgons also has reported a successful result.

Our interest in the treatment of fetal hypoglycemia became acute following the successful outcome in a case in which the patient was treated by Dr. Wilder in 1933; this case has been reported in detail elsewhere.¹ Briefly, the child was delivered by cesarean section and shortly thereafter it was found that the value for the capillary blood sugar was 43 mg per hundred cubic centimeters. At this time the child presented the convulsive movements and cyanosis that are so typical of severe hypoglycemia. By means of intramuscular injections of dextrose and frequent feedings for several days, the child was enabled to live and is still alive and well.

We now report our results in subsequent consecutive cases.

REPORT OF CASES

CASE 1.²⁸—*History.*—A married woman first came to the clinic in February 1928 complaining of the typical symptoms of diabetes mellitus which had been present since the month of her marriage August 1927. She had lost 17 pounds (7.7 kg). She was in her fourth month of pregnancy. She was instructed regarding the proper care of her condition and dismissed with instructions to take 14 units of insulin daily.

She did not return until April 1933, when she reported that this pregnancy had terminated by spontaneous abortion in the sixth month. A second pregnancy terminated in December 1929, the eighth month with the delivery of a stillborn infant. The third pregnancy terminated spontaneously at seven and a half months in February 1931. This child survived. Her fourth pregnancy terminated in the seventh month in February 1932. The child lived only seven hours.

At the time of the examination in April 1933, she was found to be in about the tenth week of pregnancy. She had had great difficulty in the control of her diabetes and frequent severe insulin reactions had occurred. She was instructed in the proper care of her condition and dismissed with instructions to take 30 units of insulin a day. She was warned to avoid insulin reactions. Every effort was made to cooperate with her home physician who took excellent care of her until she returned to the clinic in the eighth month of pregnancy.

She was admitted to the hospital Sept. 30, 1933, because she had had a severe insulin reaction the day before. Because insulin reactions prove dangerous to the fetus a cesarean section was performed October 2 at which time the fallopian tubes were resected. Her convalescence was uneventful until

5 20 p. m., October 13 when a severe insulin reaction developed. This was associated with hemiplegia but was promptly relieved by orange juice. She was dismissed from the hospital and instructed to take 50 units of insulin daily. She has not had any further trouble or any insulin reactions.

Infant's Record—The child was a boy who weighed 7½ pounds (3,402 Gm). The value for the mother's blood sugar was 60 mg and for blood sugar of the umbilical cord 30 mg per hundred cubic centimeters. Obviously the mother had received too much insulin. The infant's blood was not obtained. He was given 10 cc of 10 per cent solution of dextrose intramuscularly. This dose was repeated one and two hours later. At this time, feedings by mouth were begun. 125 cc of lactic acid karo formula and 25 cc of a 50 per cent solution of dextrose were administered at each feeding. These feedings were given every two hours for fourteen hours at the end of which time a regular feeding schedule was instituted. Thirty cc of lactic acid-karo formula was administered every three hours. The subsequent course was satisfactory.

The first patient was a diabetic woman who had been pregnant four times prior to the present pregnancy and who had only one living child. She was successfully delivered of her baby by cesarean section in the thirty-seventh week.

CASE 2—History—The patient was first seen in 1932 when she was 30 years of age. Diabetes had been discovered two years previously and had been adequately controlled with a proper diet and 24 units of insulin a day. She consulted us on this occasion for infertility. The problem of pregnancy and diabetes was discussed thoroughly and she was advised against becoming pregnant.

She returned to the clinic April 23, 1934, she had been pregnant for seven months. Her diabetes had become more severe than it had been and 68 units of insulin daily was required for its control. Her general condition was satisfactory. She was advised to avoid insulin reactions and to return in one month for cesarean section.

Cesarean section was performed at 8 a. m. on May 26, 1934, in the thirty-seventh week of pregnancy. Her postoperative convalescence was satisfactory, and her diabetes became more easily controlled. In August 1934 she reported that she was well and that only 30 units of insulin was required daily.

Infant's Record—The child was a girl who weighed 8 pounds 11 ounces (3,941 Gm). There was a marked hydramnion. At the time of the cesarean section the value for the sugar in the mother's venous blood was 180 mg per hundred cubic centimeters for the blood sugar of the umbilical cord 88 mg and for the infant, as determined by the micromethod, 41 mg. The infant was very cyanotic, 10 cc of a 10 per cent solution of dextrose was administered intramuscularly at once and oxygen was administered. Five cc of 20 per cent solution of dextrose was administered by mouth each hour for the ensuing twenty-four hours at which time the feedings of the lactic acid-karo formula were begun. Thirty cc of the formula was given every two hours. The infant also received 10 cc of a 20 per cent solution of dextrose by mouth every two hours alternating with the formula. After twenty-four hours on this schedule, the normal schedule for infant feeding was instituted and the child made normal progress. The value for the infant's capillary blood sugar which was 41 mg per hundred cubic centimeters at 4 p. m. in spite of the heavy feeding schedule was only 60 mg the following morning. From this time on it was perfectly normal.

The second patient had fairly severe diabetes and was delivered of a child by cesarean section at the thirty-seventh week. The child suffered from fetal hypoglycemia but responded well to the treatment outlined. Both mother and daughter made an uneventful convalescence. The occurrence of hydramnion is a not infrequent finding in cases in which diabetic women become pregnant.

CASE 3³⁰—History—A woman first registered at the clinic in 1927, when she was 24 years of age. She had known of

the presence of diabetes mellitus for about nine months. She had been married for two years and had not been pregnant. She was instructed in the management of her diabetes and was dismissed with instructions to take 28 units of insulin daily.

She returned to the clinic in June 1934, when she was in the eighth month of her first pregnancy. Her diabetes had been well controlled during her pregnancy. During early pregnancy she had increased her insulin dosage to 45 units because of the attendant nausea and vomiting but had been able to decrease this to 35 units in recent months. There had been some edema of the ankles during the four weeks before her last visit to the clinic, but her blood pressure and ocular fundi were normal and there was no evidence of toxemia.

June 22, 1934 a cesarean section was performed. Her diabetes became very difficult to control but within a few days the patient responded normally and a satisfactory convalescence followed.

Infant's Record—The baby who was a boy weighed 7 pounds (3,175 Gm). At the time of the operation the value for the mother's blood sugar was 165 mg per hundred cubic centimeters for the blood sugar of the umbilical cord 70 mg, and for the infant's blood sugar, as determined by the micromethod, 46 mg. Ten cc of a 10 per cent solution of dextrose was injected intramuscularly and oxygen was administered. Ten cc of a 10 per cent solution of dextrose was given by mouth every hour for twenty-four hours. In addition, an effort was made to give 15 cc of the lactic acid-karo formula every two hours but these feedings were often regurgitated. At the end of twenty-four hours the administration of dextrose was discontinued and regular feedings of the formula were instituted. For the first three days the child had numerous attacks of muscular twitching and mild convulsive movements many of which seemed to disappear after feeding. On the fourth day these symptoms disappeared and he made an uneventful recovery. While the value for the blood sugar was not obtained in each of these attacks of twitching, it is likely that the attacks occurred in spite of a normal value for the blood sugar since a single determination on the morning of each of these days revealed that the value for the blood sugar was normal.

This baby presented as an outstanding symptom of hypoglycemia the development of marked twitchings and convulsive movements, for three days following birth. The subsequent course was normal.

CASE 4³¹—History—A girl first registered at the clinic in May 1930, when she was 19 years of age. She had had typical symptoms of diabetes mellitus for two weeks. The value for her blood sugar was 200 mg per hundred cubic centimeters. Her diabetes was readily controlled and she was dismissed with instructions to take 35 units of insulin daily.

She returned to the clinic in January 1931. Her diabetes had been well controlled and the value for her blood sugar was 150 mg per hundred cubic centimeters. She had been married in the interim, had become pregnant, and had had a miscarriage in the second month of her pregnancy.

She next came to the clinic in November 1931, when she reported that her diabetes had been controlled until she became pregnant three months before. Nausea and vomiting had made control a little difficult, but at this time her diabetes was well controlled and the value for her blood sugar was found to be 83 mg per hundred cubic centimeters. She was advised as to the proper care of her condition and was dismissed.

She returned to the clinic in March 1932. At that time she had been pregnant for seven months and reported that she had been troubled with nausea and some vomiting for three weeks and that edema of the face and feet had been present for two weeks. Her family physician had found appreciable quantities of albumin and casts in the urine. Otherwise she presented little evidence of toxemia of pregnancy, the chemical composition of the blood and the ocular fundi were essentially normal. In spite of adequate medical care, she expelled a dead fetus March 28, 1932. Her diabetes was controlled and she was dismissed with instructions to take 50 units of insulin daily.

Her next visit was in July 1934, when she was two and a half months pregnant. She had reduced her insulin dosage to 10 units a day until this pregnancy, when control of the diabetes

³⁰ We are indebted to Dr. R. R. Jeffries of Waukon, Iowa, for his cooperation in the management of this patient.

³¹ We are indebted to Dr. W. J. McCarthy of Madelia, Minn., for his cooperation in the management of this patient.

again became difficult. Her diabetes was controlled, and she was dismissed taking 55 units of insulin daily.

She returned to the clinic Nov. 2, 1934. At this time she was unable to control her diabetes in spite of the fact that she was taking 80 units of insulin daily. Aside from this and in spite of the fact that she had a toxic pruritus of pregnancy, she felt well. There was no evidence of any toxemia of pregnancy, and her ocular fundi were normal. Her diabetes was difficult to control because of the associated presence of a low renal threshold, which minimized the importance of glycosuria and made necessary more frequent determinations of the value for the blood sugar.

Because of her two previous unsuccessful pregnancies and since in the interim we had learned of the importance of fetal hypoglycemia and its treatment, she was advised to remain at the clinic for delivery.

This was accomplished by cesarean section Jan. 4, 1935, in the thirty-sixth week of pregnancy. Her convalescence was uneventful and her diabetes has been satisfactorily controlled since the operation.

Infant's Record—The child, who was a girl, weighed 6 pounds 11 ounces (3,040 Gm.) and was delivered at 9 a. m. on Jan. 4, 1935. The value for the infant's blood sugar, as determined by the micromethod, was 43 mg. per hundred cubic centimeters, while the value for the sugar in the mother's venous blood was 115 mg. The child was very cyanotic and required aspiration of mucus from the trachea and artificial respiration. She was given intramuscular injections of 10 cc. of a 10 per cent solution of dextrose and 20 cc. of citrated blood, and oxygen was administered. Every hour during the morning, she was given 15 cc. of lactic acid-karo formula. Because of cyanosis, 5 cc. of a 10 per cent solution of dextrose was injected intramuscularly at noon, and beginning at 1 p. m. 10 cc. of a 20 per cent solution was administered hourly by mouth, in addition to the formula. This was continued for two days, during which time her condition remained satisfactory. The value for her blood sugar increased from 43 mg. per hundred cubic centimeters at 9 a. m. to 77 mg. at 4 p. m. and to 133 mg. at 9:30 p. m., on the day of her birth. The value for the blood sugar never became low and two weeks later it was 99 mg. per hundred cubic centimeters. The child's condition has remained satisfactory to the present.

In this case cesarean section was performed in the thirty-sixth week of pregnancy. The mother was suffering from severe diabetes and had had two previous pregnancies, the first had resulted in miscarriage and the second had resulted in a stillbirth at the seventh month of pregnancy. The living child was suffering from hypoglycemia at birth, she responded nicely to treatment. Both mother and child are alive and well.

CASE 5—History—A woman, aged 28, who came to the clinic July 6, 1935, had been examined at the clinic intermittently for nine years. Her maternal grandfather had died of diabetes and one sister has diabetes. She had had an uneventful pregnancy at the age of 23. Examination at the clinic revealed that she was pregnant and nearing term. The value for the blood sugar was 146 mg. per hundred cubic centimeters. Exton's dextrose tolerance test revealed the following values for the blood sugar: 107, 142 and 230 mg. per hundred cubic centimeters. Diabetic care was instituted and on July 10, 1935, delivery occurred spontaneously. Her postpartum course was uneventful and her diabetes has been easily controlled without the administration of insulin.

Infant's Course—A male infant who weighed 3,630 Gm., was delivered at 2:35 a. m., July 10, 1935. The value for the mother's blood sugar was 142 mg. per hundred cubic centimeters and for the sugar in the blood of the umbilical cord 112 mg. The amount of sugar in the infant's blood was not determined at this time. At 3:15 a. m. 10 cc. of a 10 per cent solution of dextrose was injected into the child's buttocks. At hourly intervals beginning at 5 a. m., 10 cc. of a 20 per cent solution of dextrose was given by mouth. His condition remained good until just after the feeding at 9 a. m., when he became very cyanotic and regurgitated the feeding. The cyanosis of the face cleared rapidly and within twenty minutes his condition was much improved. At this time the value for blood sugar as determined by the micromethod was 112 mg. per hundred

cubic centimeters. At 10 a. m. he again became cyanotic, artificial respiration was necessary and carbon dioxide and oxygen were administered, mucus was aspirated and 10 cc. of a 10 per cent solution of dextrose was injected into the buttocks. The child was kept in an oxygen concentration of from 55 to 60 per cent, he improved, although muscular twitchings were marked. No difficulty was encountered until 1:30 p. m., when he vomited. Feedings by mouth were discontinued and he was given 10 cc. of a 10 per cent solution of dextrose intramuscularly every two hours. This was continued for twenty-four hours, at the end of which time feedings of the lactic acid-karo formula were begun, 10 cc. of this formula was given every two hours. At this time (July 11) whole lactic acid milk was given and with the exception of occasional vomiting, no difficulty was encountered. July 12 his condition was good and the muscular twitchings had ceased. The administration of oxygen was discontinued and the infant received the routine care.

Even with a normal value for the blood sugar, this infant had a precarious existence for the first two days, with cyanosis, muscular twitchings and vomiting as outstanding features. Since the mother had such mild diabetes, was at term when first seen and had had an easy labor with her first child, cesarean section was not advised.

CASE 6—History—The patient registered at the clinic in December 1922 when she was a girl aged 13 years. She had had typical symptoms of diabetes mellitus for six weeks. Her mother was a diabetic patient, and there was a marked familial tendency to obesity. The value for her blood sugar was 169 mg. per hundred cubic centimeters. She was 61 inches (155 cm.) tall and very obese, she weighed 177 pounds (80.3 Kg.). She was instructed in the qualitative restriction of carbohydrates and fats and advised to return in about six months.

She returned in July 1923 and reported that after she had followed the diet for several months she had lost 15 pounds (6.8 Kg.) but that she had become careless and her weight had increased to 170 pounds (77.1 Kg.). She was advised and urged to be more cooperative.

She again returned to the clinic in February 1924, when she weighed 175 pounds (79.4 Kg.). Despite her carelessness, the value for her blood sugar was 98 mg. per hundred cubic centimeters and the dextrose tolerance test showed a normal response.

She was next seen at the clinic in June 1933. At this time she was 24 years old, 5 feet 2 inches (157.5 cm.) tall and weighed 177 pounds (80.3 Kg.). She had not followed our advice but had been most careless and had treated her diabetes only when forced to do so by the development of pruritus vulvae. Her urine contained 8 per cent sugar and the value for her blood sugar was 226 mg. per hundred cubic centimeters. There was no evidence of diabetic retinitis. A daily diet of 550 calories was employed, this was supplemented with vitamins and minerals. By August 21 she had lost 21 pounds (9.5 Kg.) and her diabetes was well controlled. She was dismissed with a stern lecture regarding her negligence.

Shortly thereafter she was married and did not return to the clinic until Aug. 30, 1935, at this time she was pregnant. Her last menstrual period had occurred Dec. 29, 1934, and her expected date of confinement was Oct. 4, 1935. She reported that until she became pregnant her weight had remained between 145 and 150 pounds (65.8 to 68 kg.). The value for her fasting blood sugar was normal as were the results of both the standard and the Exton dextrose tolerance tests. Dr. Wagener examined her ocular fundi and found the typical picture of diabetic retinitis but in addition saw a definite cotton wool patch and other evidence of toxic retinitis. Three days later there were more cotton-wool exudates and further advances in the degree of the toxic retinitis. He favored early termination of the pregnancy. The interesting feature is that the retinitis was out of all proportion to the degree either of diabetes or of toxemia of pregnancy. However because of our faith in the importance of retinal examination and because of the diabetes a cesarean section was performed September 7. September 10 Dr. Wagener reported as follows: "There seems to be less activity and the retinitis probably will recede."

September 27 he found that the evidence of toxic retinitis had largely disappeared, leaving those changes typical of diabetic retinitis. Her convalescence was uneventful.

Infant's Record—A female child, who weighed 3,624 Gm, was born at 9 a m. Its general condition was very satisfactory. The value for the sugar in the mother's venous blood was 115 mg per hundred cubic centimeters, for the sugar in the blood of the umbilical cord 85 mg, and for the infant's blood sugar, as determined by the micromethod, 115 mg. Twenty cc of a 10 per cent solution of dextrose was injected into the buttocks at the time of delivery, and 10 cc. of this solution was injected each hour until 4 p m, when feedings of the lactic acid karo formula were begun by mouth. The value for the infant's blood sugar never was below normal, and with the exception of one episode of cyanosis, which occurred two hours after birth, her clinical course was uneventful.

This patient was an obese young woman who had not taken care of her diabetes and who suffered from a progressive toxic retinitis which necessitated termination of pregnancy by cesarean section. The toxic retinitis improved following this. In this case there was no distinct evidence of fetal hypoglycemia. This may have been attributable to the mild, atypical diabetes of the mother or to the prompt and consecutive injection of dextrose into the infant. It is unusual to see diabetes behave so erratically as it did in this case, at times it was rather severe, at other times it virtually was nonexistent.

CASE 7³²—History—A woman who came to the clinic Feb 10, 1936, was in the thirty-third week of her first pregnancy. She was 30 years of age and had had diabetes for seven years, which had been well controlled with proper diet and insulin. Control of the diabetes had not been difficult during her pregnancy. Her blood pressure and urine had been normal during the early part of her pregnancy and had been normal in December 1935. Two weeks later, marked edema of both legs developed and she consulted her family physician, who found that the value for her blood pressure, expressed in millimeters of mercury, was 170 systolic and 110 diastolic, and that the urine contained albumin, grade 2, on a basis of 4. She had no symptoms other than the edema. She was ordered to remain in bed and a milk diet was advised. Within two weeks the edema had disappeared but the value for the blood pressure remained high and albumin was consistently found in the urine.

At the clinic a specimen of urine, obtained by catheterization, was found to contain a few casts and albumin, grade 4 on a basis of 4. The value for the urea was found to be 50 mg per hundred cubic centimeters of blood. Examination of the ocular fundi disclosed a diffuse chorioretinitis, which especially involved the maculae and which apparently was inactive. There was a questionable deep hemorrhage in the superior nasal quadrant of the left eye.

As a result of these observations, cesarean section was performed February 12. The postoperative course was uneventful. There was inadequate lactation. The value for the blood urea decreased to normal (28 mg per hundred cubic centimeters), and the urine contained much less albumin (grade 2 on a basis of 4) than it did at the previous examination, otherwise examination of the urine did not reveal anything abnormal. The blood pressure at the time of her dismissal fourteen days after the operation was 136 mm of mercury systolic and 96 diastolic. There had not been any change in the ocular fundi.

Infant's Record—A female infant, who weighed 1,990 Gm, was born at 9 a m, Feb 12, 1936. The values for the mother's blood sugar before and after the operation were 142 and 234 mg per hundred cubic centimeters. Blood from the umbilical cord contained 173 mg of sugar per hundred cubic centimeters, and the value for the infant's blood sugar, according to the micromethod, was 99 mg. The child was very cyanotic and listless and required artificial respiration and aspiration of tracheal mucus. Five cc. of a 10 per cent solution of dextrose was injected into each buttock and the baby was placed in an incubator in which the oxygen tension was kept at 50 per cent. At noon, 10 cc. of a 10 per cent solution of dextrose was

injected into the buttocks and the child was given some water by mouth. Just before the feeding at 3 p m the value for the infant's blood sugar, as determined by the micromethod, was found to have decreased to 33 mg per hundred cubic centimeters. At this time the child was given 10 cc. of a 10 per cent solution of dextrose intramuscularly and 10 cc of the lactic acid-karo formula by mouth. Cyanosis became pronounced. The feeding was stopped and the child was placed in the oxygen incubator. Within a few minutes her condition had improved and the feeding was finished. A 10 per cent solution of dextrose was administered intramuscularly at 5 and 7 p m. At 9 o'clock the value for blood sugar was found to be 59 mg per hundred cubic centimeters. At 9 30 she received another intramuscular injection of the solution of dextrose and another feeding of the formula. During the first night efforts were made to feed the child by mouth with the formula and 10 per cent solution of dextrose, but both were regurgitated and it was necessary to administer a 10 per cent solution of dextrose intramuscularly, every two hours.

Lack of space prevents the detailed report of the child's condition and the treatment, but at noon of the second day of life, muscular twitchings occurred. These were followed in an hour by a mild convulsive seizure and cyanosis. Five cc. of a 10 per cent solution of dextrose was injected into the peritoneal cavity and the condition improved. After this treatment the value for the blood sugar was found to be 187 mg per hundred cubic centimeters. During the second night and the third day the muscular twitchings were prominent and because of the continued regurgitation of feedings by mouth the child was given intramuscular injections of a 10 per cent solution of dextrose. At 5 p m on this day the value for the blood sugar was still low, 66 mg per hundred cubic centimeters. During the third night and during the fourth day she retained the feedings, and the muscular twitchings were much less frequent than they had been. Intramuscular injections were no longer necessary and the value for the blood sugar was 87 mg per hundred cubic centimeters. After the fourth day there was no evidence of hypoglycemia and the child gained normally. On the tenth day the oxygen tent was removed.

The toxemia of pregnancy improved following cesarean section. The value for the infant's blood sugar was normal at birth, but hypoglycemia occurred later. This child also demonstrates the fact that the symptoms of hypoglycemia, such as cyanosis, muscular twitchings and convulsions, may occur for days and even after the value for the blood sugar has increased to normal or nearly to normal.

SUMMARY

The mortality among infants born to diabetic mothers has continued high despite advanced knowledge of the treatment of diabetes. We have reported the successful delivery in seven successive cases of diabetic mothers following the principles laid down by Wilder in a case previously reported. In seven of these eight cases³³ cesarean section was performed in the thirty-third or thirty-seventh week. By so doing we have avoided those dangers which arise during the last few weeks of pregnancy and have saved the mother and child from the risk of a difficult labor. Our experience proves the occurrence of hypoglycemia in the infants of diabetic mothers, and it is considered possible, as Higgons has suggested, that some deaths of children born to normal mothers may be the result of hypoglycemia. The latter should be investigated further.

In view of our experience we have instituted the following general plan for the management of the infant of the diabetic mother for the first few days of its life. The length of time that this program will need to be maintained will vary and will depend on the degree of prematurity, the length of time before food and fluid can be taken by mouth, and the duration of the period of readjustment of pancreatic function.

³² We are indebted to Dr H W Satterlee of Lewiston, Minn, for his cooperation in the management of this patient.

³³ Since this report was written we have successfully delivered another diabetic woman.

The concentration of sugar in the blood of the mother, the infant and the umbilical cord should be estimated immediately. It would be preferable to obtain separate samples from the umbilical artery and vein. Care should be taken to be certain that the pharynx and trachea are free of mucus and amniotic fluid. This is best accomplished by maintaining the head in a dependent position, although sometimes it is necessary to aspirate with a tracheal catheter. Occasionally inhalation of carbon dioxide and oxygen may be necessary to establish respiration. When respiration has started the infant is placed in a Hess incubator equipped with a cover and connected with an oxygen tank. The flow of oxygen is regulated in order to maintain an oxygen tension of 40 to 50 per cent for the first few hours. The temperature of the incubator is maintained at 85 F. Five cc. of 10 per cent solution of dextrose is administered into each buttock. Further injections of 10 cc. of a 10 per cent solution of dextrose are given at intervals regulated by the value for the blood sugar as determined by the micromethod by the behavior of the infant and by the ability of the infant to take feedings by mouth.

Feeding is attempted within four hours. Ten cc. of a 10 per cent solution of dextrose or 7 cc. of Marriott's lactic acid-karo mixture³⁴ is given every two hours for the first forty-eight hours if it can be tolerated. Then 30 cc. of lactic acid-karo mixture is given every three hours. Sufficient nursing assistance is secured to permit uninterrupted observation of the infant for the first forty-eight to seventy-two hours. Whenever the feeding is poorly taken or whenever twitchings, convulsive movements or cyanosis indicates the development of hypoglycemia 10 cc. of a 10 per cent solution of dextrose is given by mouth if possible, otherwise it is administered intramuscularly.

The length of the period of danger from the complications of hypoglycemia cannot be predicted with accuracy. The concentration of oxygen in the incubator gradually is diminished and when the infant maintains normal color in the ordinary atmosphere the administration of oxygen is discontinued.

34 All the paraphernalia to be used in the making of the lactic acid karo mixture should be sterilized. The formula for the mixture calls for 70 Gm. of karo syrup and 930 cc. of whole milk. These ingredients are mixed and boiled for fifteen minutes. The mixture is then cooled until ice cold. One hundred and twenty drops of 85 per cent solution of lactic acid is added to the milk and karo mixture, a drop at a time while the mixture is constantly stirred. Care should be taken not to warm the mixture too much before feeding or it may curdle.

A Bold Theory Concerning the Pituitary—Histologists and pathologists still differ among themselves as to the proper description of the pituitary and their lack of unanimity applies in particular to the pars nervosa. Specific functions have still to be found for the hyaline bodies of Herring for the end organs of Tello, for the pituicytes of Bucy and for the epithelial elements in the racemose glands of Lewis and Lee and those of Guizzetti. However, consideration of these various elements and of the portal circulation recently shown to connect the pituitary and the supra-optic nuclei in the floor of the third ventricle and the confirmation of the innervation of the infundibular process via the stalk from the supra-optic nuclei make possible the elaboration of an attractive theory concerning the secretion of the pressor substance. At times the basophilic cells themselves may wander directly into the pars nervosa. Secretory products are to be seen in the form of the hyaline or colloid bodies of Herring and the end organs of Tello and can pass up the stalk to enter the ventricle directly or may go via the portal system into the general circulation. Such a bold theory can hardly be said to be established by the evidence at hand.—Baumgartner, Leona. Pituitary Basophilism and Hypertension, *J. Biol. & Med.* 7: 327 (March) 1935.

NEOPLASMS OF THE SPINAL CORD

A REVIEW OF FORTY-TWO SURGICAL CASES

R. GLEN SPURLING, M.D.

AND

FRANK H. MAYFIELD, M.D.

LOUISVILLE, KY.

There are but few organs in the human body in which neoplastic disease occurs in a more benign form and the results of surgery are more brilliant than in the spinal cord and its membranes. At the same time there is no organ in which total restoration of function following the removal of the neoplasm is so completely dependent on an early diagnosis. Unfortunately for the victims of spinal cord tumors, still too many of them are treated in the late stages of the disease—often after irreparable damage to the cord has occurred. If this condition is to be corrected, there must be a more general recognition of the early signs and symptoms of the disease and, most of all, there must be a general appreciation of the fact that a spinal cord tumor is not a rare but a relatively common lesion.

Our purpose in this report is to record our experiences over a nine year period in the treatment of forty-two cases of spinal cord tumor surgically. While these experiences have not been strikingly different from the published reports of other authors,¹ we are recording them with the belief that only through repetition and reemphasis of important diagnostic data will more of these lesions be recognized and treated during the early, hopeful stages of the disease.

INCIDENCE

There seems to be no very satisfactory way of arriving at the actual incidence of spinal cord tumors. While postmortem studies have undoubtedly contributed the most reliable figures to date, the incidence as arrived at by these studies is probably misleading.

From the Department of Surgery, University of Louisville School of Medicine.

Read before the Section on Nervous and Mental Diseases at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

because of the infrequent practice of removing the spinal cord intact and inspecting carefully the spinal canal in autopsy materials

Analysis of our own cases indicates the incidence to be considerably greater than that reported by other authors.² Approximately 2,700 patients with complaints referable to the nervous system have passed through our office during the past nine years. In this group there have been thirty-seven verified spinal cord tumors, an incidence of 14 per thousand. In this series of office patients there have been 144 verified brain tumors, an incidence of one spinal cord tumor for every four brain tumors.

This group is not remarkable as to age distribution, the youngest patient was 13 years of age and the oldest 73, as shown in the chart. As in most other reported series there is a preponderance of females, our group consisting of twenty-seven females and fifteen males.

Our statistics would indicate a rarity of spinal cord tumors among the colored race, there being but three Negroes in the group. On the basis of relative population of the two races in this locality, this incidence might appear to be significant, yet we feel that it is not a fair index in view of the disproportion between the medical and hospital facilities available to each race.

PATHOLOGY

Only thirty-nine of the forty-two tumors were verified histologically, in three cases no biopsy was made. The three histologically unverified tumors were exposed at operation and the gross appearance was so characteristic that the diagnosis of neoplasm was to us unquestionable. The following statistics therefore, are based on thirty-nine microscopically verified tumors and three tumors verified by gross appearance only.

Dividing the forty-two tumors in the conventional manner according to their location with respect to the cord and meninges, we find them distributed as follows: intramedullary, eleven cases; extramedullary but intradural, sixteen cases; extradural, fifteen cases. In the intramedullary group there were five ependymomas, one glioblastoma multiforme, one spongioblastoma unipolare, one hemangioma and three tumors microscopically unverified. The extramedullary but intradural group consisted of nine meningiomas and seven neurofibromas. In the extradural group we found four myeloid endotheliomas, three osteochondromas, three metastatic carcinomas, three fibrolipomas, one sarcoma and one neurofibroma of the dumb-bell type.

Anatomically, the tumors were distributed with respect to the vertebral column as follows: five cervical, twenty-nine thoracic and eight lumbosacral.

SYMPTOMS AND SIGNS

Since the symptoms and signs of spinal cord tumor are largely dependent on the anatomic location and size of the neoplasm, it is to be expected that each case will present its own diagnostic problems. Some late symptoms, however, are common to all spinal cord neoplasms, notably motor and sensory paralysis and sphincteric disturbances. It is the early symptoms of the slowly growing neoplasm that tax the diagnostic acumen of the physician. Neoplasms may simulate any disease of the spinal cord, therefore before one arrives at a diagnosis of degenerative disease of the organ an exhaustive study should have been made to exclude the possibility of a spinal cord tumor.

We shall not attempt to enumerate all symptoms and signs presented by the patients of this series. When

they were analyzed we found that, while they varied greatly according to the individual mode of expression, they could be grouped satisfactorily under the following general headings:

Pain—Most authors regard radicular pain as being the first and most prominent symptom of spinal cord tumor.³ This point of view has been so generally accepted that the diagnosis of tumor is often unnecessarily delayed because pain is absent even though the patient may present definite evidence of segmental cord disease. We believe that the importance of radicular pain as an early symptom has been overemphasized. While it is true that in our series root pain was the most frequent early symptom, it was present as such in but 50 per cent of the cases, in 26.5 per cent pain was absent during the entire course of the disease. In the latter group the length of time elapsing between the onset of symptoms and operation was considerably

longer than in the group having pain, the average interval in patients with pain was twenty-six months and in those without pain was thirty-eight months.

Exaggeration of pain caused by straining at stool, coughing or sneezing was an almost constant finding.

Sensory Disturbances—Subjective sensory disturbances were present in 83 per cent of our patients, objective sensory loss being present in 76 per cent. Sensory levels were demonstrated in twenty-three cases (55 per cent). In but thirteen of these, however, were we able to establish accurately by clinical examination alone the anatomic location of the lesion. In every case in which a sharply defined level was demonstrable, the patient had already rather advanced motor paralysis. This would indicate that a distinct sensory level is apt to be a late manifestation of the disease, especially when the neoplasm is benign. In analyzing the histories of the patients with sensory levels, we found that most of them had complained of paresthesias usually in the form of numbness and tingling of the lower extremities, before hypesthesia was recognized. It is in this stage

³ Bunts¹ Craig W. M. Pain in Spinal Cord Tumor. W. J. Surg. 40: 56 (Feb.) 1932. Fremont Smith. Maurice. Cord Tumor as a Cause of Abdominal Pain. Internat. Clin. 2: 171 (June) 1926. Kernohan, Woltman and Adson.² Tamaki.¹

² Elsborg.¹ Rogers.¹

of sensory loss that the diagnosis should be made if the best results are to be obtained

Motor Disturbances—Muscular weakness in some degree was the first symptom in thirteen cases (31 per cent), and only three patients came to operation without some demonstrable loss of motor power. Nineteen patients were bedridden and had been unable to walk for intervals varying from two months to four years. In most cases the paralysis progressed insidiously. But three of these patients became suddenly paraplegic after having suffered with pain for many months. In four cases motor weakness developed simultaneously with pain and was attributed by the patients to trauma.

Sphincteric Disturbances—Twenty-six patients (62 per cent) had some degree of sphincteric disturbance preoperatively. In thirteen cases the bladder disturbance was early and in thirteen it appeared late in the disease. In several cases no symptoms referable to the vesical sphincter had been noted, yet a large amount of residual urine was found.

Sympathetic Disturbances—Horsley was perhaps the first to call attention to the localizing value of vasomotor disturbance in lesions of the spinal cord. A general appreciation of these important signs was stimulated by Fay's⁴ report in 1928. He called attention to the color and pilomotor changes as well as to the sweating abnormalities in cases of spinal cord tumor. In our experience, color and pilomotor changes have been of limited value but disturbances of the sweating mechanism have proved most helpful. When a local cord lesion involves directly or indirectly the intermediolateral column of gray matter, the activity of the sweat glands below the level of the lesion is diminished. Below the level of such a lesion the skin is dry, while above this level the skin is moist. The sweat line can be readily demonstrated by gently passing the dry finger tips over the skin from below upward, and when the area of normal sweating is encountered a distinct "pull" or "hang" will be felt. In all our cases showing a distinct sensory line, this test was positive. In a number of cases the sweat line guided us to the correct segmental level of the lesion when sensory examination had proved inconclusive.

Reflexes—Abnormalities of the deep and superficial reflexes below the level of the lesion were an almost constant finding in this group, in only three instances did the patients come to operation with all reflexes normal. The type of reflex change was invariably dependent on the anatomic location of the lesion, those in the region of the conus and cauda equina showing absence or diminution of the regional tendon reflexes and those higher in the cord showing exaggeration of the tendon reflexes, with or without clonus, and abnormal superficial reflexes. In twenty-two cases (52 per cent) the paraplegia had progressed to the stage at which pathologic toe signs (Babinski, Oppenheim, Gordon or Schäffer) were present. Five patients (11 per cent) had complete paraplegia with "massing" of the reflexes.

The review of the foregoing data has impressed us with the difficulty of differentiating between the symptoms of spinal cord tumor and those arising from disease of other organs. These difficulties are graphically illustrated by the suspected disorders for which many of our patients were treated prior to their final diagnosis. Twenty-seven patients (65 per cent) received

treatment for conditions totally irrelevant to the true pathologic condition. Twelve patients (29 per cent) were subjected to surgical operations six for pelvic pain, two for suspected gallbladder disease, one for cord bladder and three for sciatic neuritis. Fifteen patients were treated for varying periods of time for spinal arthritis, flat feet, multiple sclerosis, combined sclerosis, central nervous system syphilis (negative Wassermann reactions), lead poisoning and herpes zoster.

These facts are not given with critical intent but are listed to emphasize the statement that the symptoms of spinal cord tumor may closely simulate disease of other organs. One of us (R. G. S.) in 1926 while resident surgeon at the Louisville City Hospital, performed a pelvic laparotomy on one of the patients of this group for relief of pelvic pain. Less than nine months later the same surgeon removed a large neurofibroma from one of the lumbar nerves. The symptoms that led to the first operation were in no way explained by the results of the pelvic laparotomy and no relief was experienced. Only after the passage of time were the symptoms so characteristic that the presence of a spinal cord tumor was unmistakable. Undoubtedly the correct diagnosis would have been established before the first operation had a more painstaking neurologic study been made.

The average length of symptoms before operation in the entire group was thirty-seven months. In the majority of cases, when viewed retrospectively, the symptomatology was sufficiently characteristic to have warranted a tentative diagnosis of tumor in the early stages of the disease.

CEREBROSPINAL FLUID

Study of the cerebrospinal fluid is perhaps the most valuable part of the laboratory examination of spinal cord tumor suspects. So much stress has been laid on the importance of this part of the examination, chiefly because of the refinement in the Queckenstedt test, that there seems to be a growing tendency to accept normal cerebrospinal fluid dynamics as positive evidence that no tumor exists.

In this series of patients there were eight instances (19 per cent) in which the cerebrospinal fluid dynamics was recorded as normal. We record the Queckenstedt test as being complete, incomplete and normal according to the following criteria. A complete block is characterized by an immobile column of fluid when deep jugular pressure is applied. Coughing, straining and external abdominal pressure will produce a rise even in the presence of a complete block due to engorgement of the spinal veins below the level of obstruction. An incomplete block is recorded when there is a slow rise of the fluid column after deep jugular pressure and a slow fall after its release. The fall in pressure is often associated with a new fluid level. When the fluid column rises promptly with the application of jugular pressure and falls promptly with release and the same fluid level is maintained, we consider the Queckenstedt test to be normal.

Probably the most important check on the interpretation of the Queckenstedt test is the protein content of the fluid. In no instance in our series did a partial or complete subarachnoid block exist without a very definite increase in the amount of protein. A complete obstruction was usually associated with the Frommann syndrome. Incomplete obstruction was often associated with xanthochromic fluid but the protein content was usually not sufficiently high to cause spontaneous coagu-

⁴ Fay, Temple. Vasomotor and Pilomotor Manifestations. Their Localizing Value in Tumors and Lesions of the Spinal Cord. Arch. Neurol. & Psychiat. 19: 31 (Jan.) 1928.

lation The protein content of the fluid in intradural tumors was consistently higher than in extradural tumors when an equal degree of subarachnoid block existed

Poppen and Hurxthal⁵ have demonstrated experimentally that, as long as an opening remains in the subarachnoid space as large as the bore of the lumbar puncture needle, no change from the normal should be expected in the Queckenstedt test These observations explain satisfactorily how it is possible for a relatively large tumor to be present with no demonstrable change in the mechanics of the fluid Certainly, when the patient's symptoms are suggestive of spinal cord tumor, the cerebrospinal fluid dynamics and chemistry are of real importance only when positive

The other cytologic, serologic and chemical studies of the fluid in our cases were all of relatively little importance in diagnosis The cell count was uniformly low The highest count, 26 cells per cubic millimeter, occurred in a case in which there was a rapidly growing intramedullary glioma The colloidal gold curve usually showed some atypical reduction of the gold chloride in direct proportion to the amount of protein present The Wassermann tests were negative in all cases

X-RAY EXAMINATION

The value of x-ray studies of the spinal column without the aid of contrast mediums in localization of spinal cord neoplasms has not been appreciated fully until recent years It remained for Camp, Adson and Shugrue⁶ by studying a large group of verified tumors to demonstrate conclusively the frequency with which bony changes in the vertebrae result from primary tumors of the spinal canal Many benign tumors arising within the canal, particularly neurofibromas and meningiomas, will show some local deformity in the vertebral pedicles or laminae

It was impossible to secure sufficient data in our early cases to determine accurately the incidence of such changes It might be said, however, that in the last twelve meningiomas and neurofibromas eight have shown definite bony changes in the vertebrae

IODIZED OIL

The use of iodized oil for accurate localization of spinal cord tumors is a most valuable procedure By some it may be considered an acknowledgment of inadequacy in interpreting neurologic signs, yet from a practical point of view the use of this opaque medium simplifies diagnosis in early cases and saves many laminae during operative procedures Twenty-two cases (52 per cent) of this series were studied by means of iodized oil In each instance the lesion was accurately localized In two cases a tumor was disclosed with iodized oil that was undemonstrable by neurologic examination and cerebrospinal fluid studies Only fresh iodized oil preserved in glass ampules is fit for use in the spinal canal When injected in quantities not exceeding 1 cc we have seen no harmful results that would make us fear its use By studying the patient carefully with the fluoroscope and taking serial films when necessary, perfect demonstration of filling defects has been accomplished even with this small amount

Not only is this method valuable in the accurate localization of tumors, but it further justifies its use by clearly differentiating between inflammatory adhesions

and tumors of the cord Widespread inflammatory adhesions over the surface of the cord give poor surgical results, and not infrequently a patient may be spared a needless operation by correct interpretation of the underlying pathologic condition by the use of iodized oil

TREATMENT

With the exception of malignant tumors of the vertebral bodies, we consider all neoplasms growing within or encroaching on the spinal canal to be surgical problems Benign tumors arising within the canal can usually be completely removed In twenty-three cases of this group, total surgical extirpation was possible A subtotal removal was accomplished in ten cases In the remaining nine cases there were soft intramedullary tumors and aside from the benefit afforded by the decompression nothing was accomplished surgically In six instances, however, enough tissue was obtained for histologic study

The technic of handling benign encapsulated tumors, particularly neurofibromas and meningiomas, is so well standardized that further comment is unnecessary However, it might be well to reemphasize the fact that the dural attachment of meningiomas should be excised widely or cauterized thoroughly with electrosurgery to insure against recurrence

In dealing with intramedullary gliomas we have followed a conservative practice If on exposure of the cord a tumor presents itself on the surface and appears to be reasonably well encapsulated, as is often the case with ependymomas and hemangiomas, a radical dissection is attempted This is never carried to the point, however, at which gross damage to normal cord substance becomes necessary

If a fusiform swelling of the cord is demonstrated and no tumor appears on the surface, we explore this swollen area with a small incision through the posterior commissure Should the tumor be well demarcated it is attacked radically, but when there is no evidence of demarcation no attempt is made to remove even enough for microscopic study, for regardless of the histologic structure of the growth the patient is subjected to intensive irradiation after healing of the surgical wound Three of the patients in this series have been so treated The following case history demonstrates graphically what may be accomplished by this conservative method

D W a white girl, aged 18 years had been bedridden for two months prior to operation The sensory line was indistinct and studies with iodized oil were necessary to disclose the exact level of the lesion A fusiform swelling of the cord, extending over approximately two segments was disclosed No demarcation between tumor tissue and cord substance could be identified and the wound was closed without a biopsy Intensive irradiation with both x-rays and radium extending over a period of sixteen months was employed Slow, gradual improvement ensued following the first course of treatment Symptoms regressed and again improved following further irradiation Many series of x-ray and radium treatments were given, and now nine years later the patient is walking with but little residue of her former paraplegia The accuracy of the diagnosis may be questioned but it is our belief that the patient had an intramedullary glioma of the cord It had the gross appearance of a neoplasm The symptoms disappeared with irradiation only to recur later and again disappear with further therapy

PROGNOSIS

Three deaths occurred in our group an operative mortality of 7.14 per cent One patient died of meningitis secondary to wound infection This was the only instance in which the wound did not heal primarily The second patient died five days postoperatively fol-

⁵ Poppen, J. L. and Hurxthal, L. M. Normal Cerebrospinal Fluid Dynamics in Spinal Cord Tumor Suspects. *J. A. M. A.* 103:391 (Aug.) 1934
⁶ Camp, J. D., Adson, A. W. and Shugrue, J. J. Roentgenographic Findings Associated with Tumors of the Spinal Cord Column, Spinal Cord and Associated Tissues. *Am. J. Cancer* 17:348 (Feb.) 1933

lowing the radical removal of a cervical ependymoma. The third patient died of pneumonia on the seventh postoperative day.

The degree of recovery following the removal of benign spinal cord tumors is remarkable even though there has been advanced disability. It is impossible to predict the probable degree of functional recovery from the appearance of the cord at operation. Some patients with cords of ribbon thinness will show a good return of function, while others with only moderate indentations will experience but little improvement. In general, it may be said that the rapidity with which symptoms develop is a fair index to the probable degree of functional recovery in cases presenting advanced neurologic changes. Those in which paraplegia develops slowly are apt to experience a greater degree of recovery than those in which the onset is more rapid. It is difficult to explain the variation in functional recovery from the appearance of the cord except on the basis of damage to the intrinsic circulation.

Rogers,¹ in attempting to set an index of prognosis, divides his patients into two groups—those that are spastic and those that are flaccid. He considers flaccidity, except in lesions of the cauda equina, to be a very bad prognostic sign. He expects spastic patients in whom the lesion can be completely removed to make a satisfactory recovery. Our experience has been somewhat different with regard to the prognosis of spastic cases. We view with grave concern cases that have progressed to the stage of "massing" of the reflexes. In this stage of paraplegia, we have seen but little functional recovery.

Patients with mild paraplegic signs recover completely within a relatively short time. Many of them will walk out of the hospital in from ten to fourteen days almost free from symptoms. In all cases, regardless of the length of time since the onset of symptoms, some restoration of function may be expected.

Prognosis is difficult in the glioma group. Apparently some ependymomas, even though possessing identical histologic characteristics, respond differently to irradiation. Our data on the response of other gliomas are too inconclusive to justify analysis, but it might be said that one should expect the same type of response to specific gliomas of the cord as would occur with the same type of tumor in the brain.

SUMMARY

1 The clinical, laboratory and x-ray data from forty-two cases of spinal cord tumor treated surgically were studied.

2 The percentage of neoplasms of the spinal cord that are benign is remarkably high, being 56 per cent in this series of cases. These benign lesions can usually be completely removed but if recovery without disability is to be assured the removal must be accomplished in the early stages of the disease.

3 Spinal cord tumor is a relatively common lesion and should not be the last consideration in a differential diagnosis of spinal cord disease.

4 Careful analysis of symptoms, physical examination, study of the dynamics and chemistry of the spinal fluid, x-ray examination of the spine and studies of the subarachnoid space with iodized oil will in every case disclose the presence and location of the lesion even in the early stages of the disease. The importance of pain as an early symptom of spinal cord tumor has been overemphasized. It was an early symptom in but 50 per cent of our patients and 26 per cent of them had no pain at any time.

5 Treatment is always surgical except in certain malignant tumors of the vertebrae. Complete removal of benign tumors is usually possible. Gliomas of the cord can occasionally be completely removed, but in most instances one must be satisfied with a subtotal removal followed by intensive irradiation. In certain gliomas even microscopic diagnosis should be dispensed with if biopsy would incur damage to normal cord substance.

6 It is impossible to predict the degree of functional recovery from the appearance of the cord at operation. Some cords of ribbon thinness will show a good return of function, while others with only moderate indentations will show very little recovery. Every patient with some preservation of function below the level of the lesion, even though it is only an isolated reflex, will experience improvement after the removal of the neoplasm.

ABSTRACT OF DISCUSSION

DR PERCIVAL BAILEY, Chicago. This presentation corresponds closely with my experience. I note the absence of children in the material, so I might supplement the presentation of Drs. Spurling and Mayfield with some remarks concerning these lesions in infancy and childhood. After several years' experience with the material from three large children's clinics, I am impressed with the extreme rarity of intraspinal tumors in infancy and childhood. Whereas as the authors have pointed out, the ratio between intraspinal and intracranial tumors in adult life is 1/4 or 1/6, in childhood this proportion is much greater, in my experience somewhere around 1/20. Also the pathologic character of the tumors in infancy and childhood is entirely different from that of the adults. The favorable character of these lesions in adults is largely due to the presence of a considerable proportion of meningeal tumors and neurofibromas that are encapsulated and can be totally removed. In childhood and infancy this is not true. The meningiomas and neurofibromas with the exception of those which are multiple usually begin to develop about the age of 15. Under that age they are rarely found. The tumors at this age are usually intramedullary gliomas or lipomas or dermoid cysts, which are much less favorable for operation. I have also been impressed in children with the importance of the erosion of the laminae to which attention was first called by the physicians at the Mayo Clinic. This is much more obvious during infancy and childhood than it is in adult life, probably for the reason that the bones are much softer. I should also like to emphasize what the authors said about the removal of intramedullary tumors. Intramedullary gliomas are predominantly ependymomas, as Dr. Kernohan has pointed out and these are benign tumors. I had one child 8 years of age with an intramedullary ependymoma in the cervical region. The child was having great respiratory difficulty. I made only decompression and split the posterior columns of the cord to make a biopsy. That child is still well and improved after eight years and he has had no x-ray treatment. In other cases I have made extirpation of these ependymomas. Certainly none of them have done any better than the child in whom I split the posterior columns and let the child alone without even giving him x-ray treatment so that one may question whether it is necessary to go to any great difficulty in removing one of these ependymomas. I wouldn't make the same statement concerning other types of intramedullary gliomas which one certainly ought to attempt to remove in many cases and should certainly irradiate afterward. They are however rare.

DR FRANK R. TEICHENOR, Kansas City, Mo. Concerning tumors in childhood I had one several years ago in a child 2 years of age. This tumor was reported by the pathologist as a meningioma. However the child lived five years and died of pneumonia. There was no autopsy. I cannot discuss the statistical aspect of this paper as my own statistics are not up to that point but certainly too much cannot be said for the early diagnosis of spinal cord tumors. It is not uncommon to receive patients who have had gallstones removed. I receive

observed a patient who was operated on and the gallstones were actually found, but the pain did not subside. During the period the patient was in bed recovering from the operation, she developed a paraplegia. Unquestionably the diagnosis of spinal tumor could have been made before the operation. Urethral or renal colic is another very frequent diagnosis. I have seen several cases in which renal and urethral operations were performed without relief, and afterward a spinal cord tumor was found. Those, of course, were the result of compression of the roots with pain phenomenon. Multiple sclerosis should be considered. In many instances multiple sclerosis is considered early and later symptoms of a spinal tumor become evident. In that instance, of course pain is not a feature. Concerning the Queckenstedt sign I find that even in the face of a negative one I am frequently able to locate the tumor by seating the patient before the fluoroscope and watching the progress of iodized oil as it passes down. Even in the absence of a block, it will hang in a good many instances. I have recently had a rather interesting series of cases so far as the pathologic condition is concerned which were not mentioned here. Melanomas, which I consider primary, may be classified under sarcomas. I have recently observed an extradural tumor which had been diagnosed by several pathologists as a lymphadenoma. Thus far, although I haven't searched the literature completely, I have found no mention of lymphadenoma. Another interesting lesion, which caused a marked dilatation of the spinal canal, was a herniation of the arachnoid through a perforation of the sleeve of the dura over one of the roots with the formation of a very large extradural cyst, apparently of long duration, because of the extensive dilatation of the spinal canal. This was quite evident on radiologic examination. The cyst was removed completely. The pedicle of attachment was found on the dural sleeve of this root. Behind the attachment the spinal cord was encased in normal dura, with a normal subarachnoid space.

ACUTE LARYNGOTRACHEOBRONCHITIS

LIVING PATHOLOGIC CONDITIONS SEEN IN ACUTE RESPIRATORY DISEASES

CHEVALIER JACKSON, MD

AND

CHEVALIER L. JACKSON, MD

PHILADELPHIA

Our purpose in this paper is to present the differences among certain acute respiratory diseases of children based on the objective appearances of the mucosa of the larynx and the tracheobronchial tree. These appearances represent living pathologic changes. Therefore they are, we venture to think, of the utmost importance to the physician as bearing on the pathologic conditions of the airway which the physician is called on to diagnose and treat in the child battling for his life against these pathologic states. Mention will be made of the clinical features sufficient to associate these appearances with the diseases considered.

NOMENCLATURE

The term "fulminating, acute, infective, nonspecific laryngotracheobronchitis," however descriptive it may be, is certainly not brief nor is it otherwise suitable beyond criticism. The disease is certainly not diphtheritic but it remains to be proved that it is not primarily or secondarily specific. Except as to rash, the malady has almost as much claim to clinical specificity as scarlet fever. "Nondiphtheritic laryngotracheobronchitis" is nearly as bad, and in addition it is a negative title. Influenzal tracheobronchitis, by which the disease

has been described,¹ is appropriate in the cases in which the influenza bacillus is found predominating. This constitutes about 5 per cent of our cases, though we have no means of knowing in how many cases this organism may have been the vanished primary invader. Moreover, most of the cases of the disease commonly called influenza and the grip are also primarily or secondarily streptococcic in character.

INCIDENCE AND EPIDEMIOLOGY

It is impossible to supply any exact figures in incidence of acute laryngotracheobronchitis because relatively few of the cases are recognized as a distinct morbid entity. Curiously, the literature shows that, though the existence of such an entity was recognized by at least two keen observers over a century ago,² the disease as such in the patient has been quite generally overlooked. The occurrence being chiefly during epidemics of so-called influenza, many of the cases are recorded under that name. Most of the fatal cases are registered in vital statistics as bronchopneumonia and pneumonia. Among these patients some really had bronchopneumonia but only as a secondary development, in almost all instances the primary disease was unrecorded. For this reason statistics are valueless as criteria of incidence.

PATHOLOGY

At autopsy pathologic changes of laryngotracheobronchitis are not as abundantly recorded as are those of diphtheria, but records are accumulating. Autopsies, however, show end results, we have thought it best to limit our presentation to the heretofore unrepresented living pathologic changes, the condition with which the physician has to deal in the living patient. The mucosa of the larynx is a deep red, slightly less deep on the cords. The subglottic tissues on each side extend medially, showing as mounding, intensely red, semi-elliptic folds, one below each cord.^{1a} These swellings are peculiar to children and are due to the loose connective tissue in the conus elasticus in childhood. Small patches of secretion may be seen but they can be wiped away cleanly, leaving no eroded or bleeding surface, there is no ulceration, no membrane comparable to that in diphtheria. The living pathologic condition of the bronchi is interesting and important. The appearances at the progressive stages have been described as follows:^{1c} "The tracheal mucosa is reddened. Its color deepens. Swelling of the mucosa begins. Later on exudate forms, at first serous, then mucoid, then purulent and finally thick, tenacious and exceedingly difficult of expectoration even by the robust adult. In infants

Owing to lack of space this article has been abbreviated in THE JOURNAL. The complete article including a color plate will appear in the reprints, a copy of which may be obtained from the authors.

who are naturally almost incapable of expectoration, death may occur from inability to rid the air passages of secretion (drowning of the patient in his own secretions). The bronchi, or even the trachea itself may be occluded by mucosal swelling, or edema, actually causing death by the stenosis. Both these conditions are independent of bronchopneumonia, which may or may not exist." Subsequent observations have fully confirmed these observations. As in other conditions the rings, so characteristic of the normal, are obliterated by swelling. Some orifices are noted as filled with pus, and absence of bubbling indicates no passage of air. Still other orifices are found obstructed with straw-colored or brownish crusts. These crusts have the appearance of dried serum with little admixture of pus. It is true that thick pus too viscid to run down the glass walls of the collector is seen in various bronchial diseases,⁵ but no such dry gumlike and crusted secretion as that previously described is ordinarily seen in any disease other than the malady under consideration. In rare instances an outstanding feature of the endobronchial picture is the dry, sometimes even glazed, appearance of the tracheobronchial mucosa.

Laryngeal and Bronchoscopic Appearances of Diphtheria.—By means of direct laryngoscopy in children one sees at first an intense inflammation of the laryngeal mucosa, and even in the early stages it is noted that the subglottic tissues swell out so as to approach each other, looking, as protruded from each side below the cords, somewhat like the turbinal bodies in the nose. The membrane may come on any part of the larynx or on the subglottic swelling. Sometimes the membrane does not appear in either the fauces or the larynx. We have seen many such cases. The patients are always quite dyspneic and ashy in color. On putting down a

Therefore no attempt should be made to examine the larynx without proper preparation for a bronchoscopy, including bronchoscopic forceps that can be used to remove the obstructive exudate in case it is encountered. Many, many times we have saved a child from asphyxia by removing great masses of membrane with the bronchoscopic forceps. Early in the disease the membrane is tightly adherent and leaves a bleeding surface if it is pulled off. The children, however, are seldom seen in this stage, usually, when the bronchoscopist is called the membrane is being shed and there may be obstructive, cast-off membrane. Before this stage of shedding the membrane may look like edematous polyps in the nose, and whitish grapelike masses may be drawn up through the bronchoscope with the forceps, causing a sucking sound as they come through. When these appearances are encountered by the experienced observer there can be no question about the diagnosis. There are membranous and exudative forms of laryngitis and tracheitis but none are accompanied by exactly the clinical picture here described.

Laryngoscopic and Bronchoscopic Appearances in Laryngismus Stridulus.—In almost half the cases of acute laryngotracheobronchitis that we have seen the primary diagnosis of "spasmodic croup" had been made on an inferential basis. No one could ever make such a mistake by direct examination. It therefore seems proper to describe the laryngoscopic appearances in laryngismus stridulus. In most cases of laryngismus stridulus in children examined during the attack the mucosa is found to be lavender or violet but otherwise normal. In severe cases there is not only a glottic spasm but a laryngeal sphincteric closure. In these cases the cords are hidden by the closure of the ventricular bands, the aryepiglottic folds are crowded over in support of the bands. In most cases the glottic closure will relax and the child draw a deep breath. It will then be seen that except for the lavender, violet or grayish color of the mucosa, the larynx is normal. If the sphincteric closure does not promptly relax, allowing the patient to take a deep breath, the proper thing to do is to introduce gently a small bronchoscope and then start the child's breathing, if it has already stopped by insufflation of oxygen plus carbon dioxide, 5 per cent, combined with artificial respiratory movements. After respiration is fully established and going on rhythmically, the bronchoscope can be removed. It will then be seen that the glottis will abduct widely on

Fig. 2—A collecting tube showing pus aspirated from the bronchi of a baby, aged 15 months, very ill with streptococcal laryngotracheobronchitis. Aspirations with a catheter through the tracheostomy cannula by the nurse were necessary at frequent intervals. Many times the aspirations brought the child back to life from a seemingly moribund condition. Each time the partial atelectasis at both bases simulating pneumonia completely cleared. The obstructive character of the pus is obvious from the fact that it was so thick and tenacious it would not run down the inverted glass collecting tube. All together about fifty of these tubes were used. Additionally plugs and crusts were formed of this secretion (compare figure 3).

Fig. 1—Roentgenogram showing obliteration of the tracheal lumen complete at the point A by mucosal swelling complicating streptococcal laryngotracheobronchitis in a child aged 15 months. Recovery followed repeated bronchoscopic removal of plugs and crusts of tough gummy adherent secretion that produced atelectasis and impending asphyxia (compare figures 2 and 3).

bronchoscope, one finds obstructive exudate in the trachea or in either or both bronchial orifices. In most of these cases by the time the bronchoscopist is asked to make his examination the child is extremely dyspneic.

⁵ Jackson, Chevalier, and Jackson, C. L. Peroral Pulmonary Drainage: Natural and Therapeutic, with Special Reference to the Tussive Squeeze. *Am. J. M. Sc.* 186:849 (Dec.) 1933.

inspiration, especially the deep inspiration that the child will take because of the air hunger and the stimulus of the accumulated carbon dioxide on the respiratory centers. Thereafter, for a time at least, breathing will go on regularly with the laryngoscope in place but with the bronchoscope removed. Any one accustomed to examine the larynx without anesthesia will promptly recognize the abnormal sphincteric closure and the discolored but never red mucosa as in strong contrast to the deep fiery red that is present in both diphtheria and laryngotracheobronchitis. The difference between the latter two conditions has already been given. If the patient is examined a few hours after a croupy attack, the contrast between laryngismus stridulus on the one hand and the two diseases mentioned on the other is still more striking. The mucosa of the larynx and trachea will be found perfectly normal, but there is usually an abnormal flaccidity of the margins of the laryngeal orifice that is unmistakably typical.

It might be added here that our opinion is that in laryngismus stridulus the exciting cause of the attack is the sudden violent inspiration started by the entrance of secretions into the larynx. The nerve paths traveled are phylogenically very old, they are concerned with the sphincteric closure of the airway against the entrance of anything other than air. To this primary closure is added the secondary passive closure due to indrawing of an anatomically flaccid, usually rachitic, laryngeal orifice. It is this pathologic flaccidity that explains why relatively few children are affected to the degree noted in laryngismus stridulus. Mouth breathers are especially prone, because swallowing is almost impossible with an open mouth, hence secretions accumulate in the laryngopharynx and overflow into the larynx. This happens with any mouth breather, but lacking the rachitic, flabby, laryngeal orificial tissues the reaction is merely a partial awakening, a choking and a clearing away of the intrusive laryngeal secretions.

CLINICAL FEATURES

The symptomatology and almost all the clinical features of acute laryngotracheobronchitis are the same as those of laryngotracheobronchial diphtheria before the days of antitoxin. The chief differences today arise from the fact that we have no remedy for streptococcal infections that is in any degree comparable to diphtheritic antitoxin, the disease must run its course, usually long, and we are fortunate if we can keep the patient alive until the course is run. Space limits here forbid detailed reports of cases. The important clinical features were described by Chevalier Jackson^{1b} and illustrated by two typical cases, one an influenzal infection with recovery, the other streptococcal and fatal. A typical case may be cited here.

A typical case of streptococcal laryngotracheobronchitis with a misleading history and a favorable termination. A boy, aged 15 months, two days before admission fell and struck his head. Cold compresses were applied. The mother stated that "his nose started to run as if he had a cold in the head." That night the breathing became "heavy," and a cough started and soon became "croupy." The mother stated that the child had been playing with dried beans. Two unassociated physicians in succession prescribed medication but the breathing became more and more labored and Dr. Ralph Tyson was called. He made a diagnosis of laryngotracheobronchitis and advised direct laryngoscopic examination, for which the child was brought to Temple University Hospital. On admission the temperature was 104 F, respirations 30, pulse 110. There was marked indrawing at the suprasternal notch and the epigastrium. The condition was toxic. The color was slightly cyanotic, especially the fingers and toes. Dr. Ralph Tyson found dulness through-

out the chest most marked posteriorly and laterally. Coarse rales were heard all over on both sides. An oxygen tent with humidifier gave temporary improvement but asphyxia impended. Preparations were made for tracheotomy to relieve the obvious obstructive laryngeal dyspnea and for a bronchoscope to be inserted to maintain the airway during the tracheotomy. Direct laryngoscopy revealed cords fixed in the position of partial approximation. Immediately below the cords the lumen was just about obliterated by reddish swellings that met in the midline. A mucopurulent secretion was seen in the larynx and in the subglottic region. A 4 mm bronchoscope was inserted and a quantity of thick tenacious pus was aspirated. The relief of the dyspnea was immediate and the child became tranquil. The bronchoscope was held in situ to maintain an airway while a low tracheotomy was done. For four or five hours the condition of the patient was very satisfactory under catheter aspirations by the nurse, then he grew rapidly worse. The temperature was not high but the respiratory and cardiac rates rose rapidly. The breath sounds disappeared at the bases and the percussion note became dull. Bronchoscopy and the removal of plugs of thick secretion restored the patient to a very satisfactory condition. A few hours later the recurrence of symptoms and signs of obstructive secretions again required bronchoscopic removal. This cycle was repeated many times before the bronchial inflammation subsided and the mucosa and secretions became normal. The Proetz treatment was given the nose. Bacteriologic reports at first were Micrococcus

Fig. 3—Specimens of plugs and crusts of inspissated secretion bronchoscopically removed from orifices of bronchi where they were causing recurrent attacks of obstructive atelectasis simulating pneumonia in a child aged 15 months. These crusts were composed of bloody serum and the pus referred to in the legend to figure 2.

carrhalis, later *Streptococcus haemolyticus*. Medical care and management were directed by the pediatrician Dr. Ralph Tyson. Decannulation and perfect recovery followed in due course.

The foregoing case is not unusual in the misleading character of the preliminary history, and it is typical of a streptococcal laryngotracheobronchitis running a favorable course under treatment.

CONCLUSIONS

1 Acute laryngotracheobronchitis is a clinical type. It occurs most often and most severely during epidemics of so-called influenza. In from 3 to 5 per cent of the cases the influenza bacillus seems to be causative, occasionally other organisms seem responsible, but over 90 per cent of the cases are primarily or secondarily streptococcal. The mortality in children under three years is about 70 per cent.

2 In laryngismus stridulus, observations of the living pathologic condition show that the mucosa is lavender, violet or grayish but is otherwise normal and that the discoloration quickly disappears, when the airway is laryngoscopically held open, without leaving a trace of abnormality. It is suggested that attacks may be

due to inspiration of pharyngeal secretions during sleep. The consequent sudden and violent efforts to draw in air draw in the laryngeal orifice in a sphincteric closure. The nerve paths followed are phylogenically very old.

3 In diphtheria limited to the larynx and tracheo-bronchial tree there is a fibrinous exudate that objectively is very different from the inflammatory exudate seen in streptococcic infection of the same mucosal areas.

4 In acute laryngotracheobronchitis the outstanding feature of the bronchoscopically observed pathologic condition is the bronchial obstruction by inspissated secretion which the weak or absent cough reflex is unable to expel. Therefore the following points are important in the treatment of this disease:

(a) The routine administration of atropine and opium derivatives is illogical in theory and often fatal in practice.

(b) The superheating of the air in our hospitals and dwellings contributes largely to inspissation of secretions. Outside air at zero contains little water even at the dew point. When we heat this air to 70 F it becomes extremely desiccating to the secretions and almost caustic to the mucosa. The air surrounding the patient with laryngotracheobronchitis with inspissating secretions should be humid to saturation.

(c) In this disease an impaired percussion note and increased respiratory rate usually mean not pneumonia or bronchopneumonia but obstructive atelectasis.

(d) These signs call for peroral or tracheostomic aspiration of secretions. In extreme cases forceps removal of crusts is the only means of saving life. Such potentially fatal circumstances can be prevented by humid air and the avoidance of atropine, opiates and other desiccating medicaments.

5 In the treatment of babies one must remember that, relatively, a cat in the laboratory has nine lives, a dog has about three, but a baby in his crib has only one. It is a paramount duty of the pediatrician and the family physician to see that the baby gets intervals of rest and that such rest is not interfered with by too many examinations, by serum reactions, by torturing urticaria and by subdermal abscesses. This is not a criticism of scientific medicine but a reminder to the clinicians that they are the balance wheels of the therapeutic machinery.

ABSTRACT OF DISCUSSION

DR. JOSEPH BRENNEMANN, Chicago. I hope that "streptococcic bronchitis" will not replace the term in common usage, laryngotracheobronchitis. The latter is descriptive and both clinically and pathologically adequate; the former is based on etiology and may call for recantation later. The Jacksons have said that the essential problem is that of the pediatrician and the general practitioner. One can only agree with that statement if it is meant to point out the great importance of early recognition of the nature and gravity of the disease. The one important person is the bronchoscopist; the one important thing to do is to keep the airways clear so that the child will not die of atelectasis due to obstruction by the characteristically thick, tenacious secretions. Compensatory emphysema doubtless also enters into the picture when no longer adequately compensatory. The all important measures to keep the airways clear are bronchoscopic aspiration as often as necessary and tracheotomy. The latter both relieves the subglottic obstruction and facilitates the removal of secretions through a catheter and negative pressure apparatus or through the bronchoscope itself. Intubation seems contraindicated. It frequently does not relieve the laryngeal obstruction and does not function in removing the

all important secretions. Contrary to the situation in laryngeal diphtheria the disease often lasts a long time and requires long retention and usually frequent reintroduction of the intubation tube. A child is now at the hospital who was intubated some fifty times elsewhere, who has a contracted larynx, no voice, a tracheotomy tube in place for months that may remain indefinitely. Bronchopneumonia may follow tracheotomy but it is the lesser hazard. Doubtless too, as Chevalier Jackson pointed out years ago, in laryngeal diphtheria what is thought to be pneumonia is more often bronchial obstruction in diphtheria due to membrane, here to thick secretions. I heartily agree to what has been said about atropine or belladonna. I am tempted to say the same of nearly all cough medicines that impair the tussive reflex and, while helping the parents, harm the child. In former experience nearly all of these children, usually infants, died. Recently most of them have lived because a bronchoscopist, trained by the Jacksons who devotes all his time to endoscopy is readily accessible—one of the greatest comforts of my professional life. Parenthetically, not one twentieth of the endoscopist's work has to do with foreign bodies in the usual sense.

DR. CLIFFORD G. GRULEE, Evanston, Ill. This meeting has lost something in not having seen the original paper, as I have, for there were several statements in it that were very interesting. One of the characteristics of the paper that struck me was the vagueness of the definition of the condition. I am not sure I know just exactly what they are talking about. Apparently Dr. Brennemann does. If they are talking about spasmodic croup that is one thing. If they are talking about a streptococcic involvement of the trachea, larynx and bronchi, that is another. That wasn't very clear in the original paper. The streptococcic infections have been known for a good many years. The inspissation of the mucus and the secretions have been recognized. The one thing that should be done that has not been stressed sufficiently which would prevent a great many bronchoscopic examinations and the necessity for them is that the child should immediately be put in a steam tent and kept there. When I say a steam tent I mean a steam tent. I mean that the steam shall be very thick and shall be kept up without any interruption over hours. In many instances, I know the condition about which we are talking, the steam tent does get results. I am not at all sure that I can agree with the authors or with Dr. Brennemann as to the danger of using atropine or belladonna in these cases. For the last twenty years I have used atropine and belladonna and steam in all my cases of respiratory infections of almost every sort except lobar pneumonia. I feel the results have been very good and I think that some of these can be attributed to the action of the atropine. On the other hand I think we owe to Dr. Chevalier Jackson and Dr. Chevalier Jackson Jr. a great debt for bringing to our attention two things: first, the pathology of this condition as seen in the bronchoscope and, second, the fact that so much of the disturbance is on the basis of the inspissated secretions.

DR. ISAAC A. ABT, Chicago. When a baby with laryngeal stenosis is seen in the home or brought to the clinic he needs immediate attention. Often it is difficult to classify at once the bacteriologic nature of the laryngotracheobronchitis. The Jacksons have already pointed out that the condition in question may be due to any one of a number of organisms. I am inclined to agree with Dr. Brennemann that the designation of "streptococcic laryngotracheobronchitis" may be too inclusive. While it is true that diphtheritic laryngitis is not as frequent at present as in former times, nevertheless it must be borne in mind. In the earlier years laryngeal stenosis due to diphtheritic invasion of the larynx seemed to occur more frequently than the variety of laryngotracheobronchitis that the Jacksons have just described. Cultures were always made and the pharynx was inspected carefully though immediate relief of the stenosis was indicated then as now. A great deal was said about intubation for relief of laryngeal stenosis. Indeed the introduction of the tube was a fine art though there are few intubations being performed nowadays and the laryngologists have favored tracheotomy. These children come into the hospital as emergency cases. They are extremely dyspneic and desaturated. The indication is for immediate relief. The vogue today is to

use the Mosher tracheocannula or so called life saver. Intubation would probably be an equally efficient and safe procedure and in some instances might tide the patient over until the edema and inflammation had subsided and the air passages had resumed a nearly normal function. It is true that intubation might not succeed in every case and a subsequent tracheotomy would have to be performed though on the other hand if the intubation tube is introduced skilfully no harm would be done. With reference to blood transfusion in these cases I must admit I am somewhat skeptical as to its indication. My impression is that these patients do not need blood. What they need is air. I realize that blood transfusion is widely used and in moderately severe cases no treatment is complete without one or more transfusions. Nevertheless one should meet the immediate indication and not supply blood when air is urgently needed. I would hesitate to place these strangling children in a steam tent. The amount of oxygen in these tents is limited. The exhaled air will sooner or later reduce the volume of available oxygen. If one wishes to supply moisture I think it would be better to increase the humidity of the whole room. This can be done by moistening large turkish towels and suspending them about the room so that the air is saturated to the dew point. In this way perhaps some of the gummy inspissated matter may be liquefied and expectorated.

DR. RALPH M. TYSON, Philadelphia. It has been my privilege to work with the Jacksons in a number of these cases. Cultures taken from the larynx and trachea showed that they are not diphtheritic. We have found the streptococcus and in one case the hemolytic *Staphylococcus aureus* as the infecting organism. Another point I want to emphasize is the value of oxygen plus the moisture. A machine can be arranged whereby the two can be obtained at the same time. I must disagree with Dr. Grulee with regard to the use of atropine or belladonna. It has been our experience that the drug is a dangerous one to use in these cases. The question also comes up as to just how one is going to procure rest for these children. The use of opiates has been tried and we have just about abandoned the use of either paregoric or codeine. I want to make it clear that we do not use transfusions during the acute stage. It must be remembered that these children have gone through a serious infection that is not over in a day or two and often lasts weeks and sometimes months. It is then of course that we use the transfusions.

DR. CHEVALIER L. JACKSON, Philadelphia. Dr. Tyson has almost closed the discussion for me, but there are one or two things on which I should like to comment. I was glad that Dr. Brennemann emphasized so convincingly the importance of proper postoperative care of the tracheotomic patient. Too often physicians and surgeons feel that the battle is won when a child has a tracheotomy tube in his trachea. Too often twenty-four to forty-eight hours later the child dies because of inadequate postoperative care. Crusts form in the trachea or swelling of the tissues lifts the lower end of the tube out of the trachea. One of many, many things may happen. A cannula may be absolutely clear of any obstruction after autopsy it is reported that the trachea and the tracheotomic cannula were found entirely clear—but were the main bronchi clear? That is equally important. We have heard enough about atropine and opiates from the pediatricians. While that subject was discussed at length in part of the paper that part was not read. I will let Dr. Tyson's discussion of that phase of the question stand without further comment. To avoid confusing the issue, since we are primarily discussing acute infective laryngotracheitis, I have limited myself to presenting here only the portions of the paper which deal directly with this condition. In the full paper as prepared for publication we attempted to describe the endoscopic appearance of the larynx and tracheobronchial tree in acute infective conditions such as acute laryngotracheitis and diphtheria, as well as that in certain other conditions. As to the steam tent I think Dr. Abt makes an excellent point in suggesting that we use a steam room rather than a steam tent, because in a steam tent too often there is heat. Heat, we think, is bad for these little patients. A steam room or the oxygen tent with cool, humidified oxygen is our preference in the Temple Clinic at the present time.

COMMON TUMORS OF THE EYELIDS

C. S. O'BRIEN, M.D.

AND

A. E. BRALEY, M.D.

IOWA CITY

Tumors of the eyelids are quite common, most of them excluding chalazia arising from the skin and its appendages. The greater number of such growths are benign but some are malignant.

In order to determine the types of common lid tumors and the relative frequency of each type and in an attempt to establish more accurate clinical diagnoses clinical and pathologic studies were made in a series of 100 consecutive cases.

Pathologically these 100 tumors were classified as follows: papillomas 34, nevi 17, carcinomas 15, sebaceous cysts 13, fibromas 5, sudoriferous cysts 4, hemangiomas 4, dermoid cysts 2, molluscum contagiosum 2, malignant melanoma 1, sweat gland adenoma 1, xanthelasma 1, granuloma 1.

Papilloma (cutaneous wart)—A benign neoplasm characterized by a localized overgrowth of epithelium and the underlying connective tissue. It is apparently the most common tumor of the lids. Such growths were found in middle aged or elderly persons, were usually single but occasionally multiple and, although most frequently located at the margin of the lid also appeared in other parts of the lid. Growth was slow, in most cases there had been no noticeable increase in size over a period of years. Typical papillomas were small, fairly firm and pedunculated and had nodular warty surfaces, they were not unduly pigmented, and consequently they were of approximately the same color and shade or only slightly darker than the surrounding skin. The most typical characteristics of papillomas were the pedunculation and the papillated surface, but occasionally the tumor arose from a broad base and its surface was smooth or only a bit uneven and in such cases it was difficult or impossible to differentiate clinically from a nevus or fibroma or even an early epithelioma. Ulceration of the surface was noted in only one case.

Under the microscope papillomas appeared to be formed by an overgrowth of epithelium and proliferation of the underlying connective tissue. The epidermis was thickened and large papillae were formed. The basal cells of the epidermis contained small amounts of pigment here and there and many mitotic figures, while the superficial cells showed excessive keratinization. Underlying the thickened epithelium and extending into the papillae was a variable amount of more or less dense, vascularized connective tissue stroma, which invariably showed perivascular and sub-epithelial infiltrates composed of lymphocytes. In one tumor the infiltrates were composed of lymphocytes and polymorphonuclear leukocytes.

Nevus—A congenital benign tumor characterized by a peculiar type of cell believed to arise from the end-apparatus of the cutaneous sensory nerves. Several nevi were seen, and it is apparently a common tumor. They usually occurred singly and often were located at the margin of the lid. According to the histories the nevi, with one exception, grew slowly or remained

From the Department of Ophthalmology, State University of Iowa College of Medicine.

Read before the Section on Ophthalmology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

stationary over a period of years. Typical nevi were small to medium size, firm sessile growths, having smooth, delicately pigmented surfaces. This appearance varied and often it was difficult to differentiate a nevus from a papilloma, fibroma or early epithelioma, for example, two of the nevi were pedunculated, one

Fig. 1—Nevus

was translucent, one was soft, in several no pigment was seen and in two the surface was nodular or papillated. Pigmentation was never dense, consequently it was not considered characteristic.

The origin of nevi remains unsettled, they have been described as arising from the basal cells of the epithelium, from the endothelium of the blood vessels, from chromatophores and from the end-apparatus of the cutaneous sensory nerves. At present the tendency is to accept the last of the aforementioned theories, i. e., Pierre Masson's theory of derivation from the cutaneous sensory nerve end-apparatus. Microscopic

Fig. 2—Wall of sebaceous cyst

studies revealed two types of cells: nevus cells and the pigmented cells. The tumors were composed of nests, whorls or cords of nonpigmented, closely packed nevus cells lying in the dermis. The epithelium was usually normal but occasionally showed some downgrowth in isolated areas. The nevus cells were round or polyhedral and had large nuclei. Many multinucleated or giant nevus cells

were seen. A few fusiform pigmented cells known as melanoblasts, were present in and around the margin of the nevus cell groups. The stroma was composed of more or less dense connective tissue which interlaced between the nevus cell nests but did not extend between individual cells. Blood vessels were scanty as a rule. With one exception these tumors were evidently quiescent and no mitotic figures were found in the nevus cells.

Carcinoma—A malignant epithelial neoplasm characterized by proliferation and downgrowth of epithelium, with invasion through the lymph channels and destruction of the surrounding tissues. There are two types of skin carcinoma: the basal cell carcinoma or rodent ulcer, a relatively benign growth which is common in the eyelids, and the more malignant epidermoid carcinoma or acanthoma, which is not so common about the eye. Both types grow slowly and are locally malignant in that they invade and destroy the neighboring tissues but only the epidermoid carcinoma metastasizes to distant organs.

As is usual, all such tumors in this series occurred in persons beyond 40 years of age. Thirteen of the fifteen cases were rodent ulcers and two were epi-

Fig. 3—Neurofibroma

dermoid carcinomas. A clinical differentiation between the two types was not possible in the tumors here reported, since locally they have much the same appearance and no distant metastases were evident. Several of the neoplasms were located near the medial canthus, a favorite site for rodent ulcer, however, others appeared in other parts of the lids. All were more or less elevated and had the characteristic indurated, rolled, nodular margins. Four of the early, smaller tumors had not yet ulcerated but in each the surface showed a central depression; the others presented a central, depressed, ulcerating, granulating surface covered with crusts.

The rodent ulcers under the microscope were composed of columns and irregular masses of deep blue staining cells which extended downward and infiltrated into the dermis and subcutaneous tissues. The cells resembled the basal layers of the epithelium but as a rule were somewhat smaller, they were small spindle or polyhedral cells with large nuclei and a scanty cytoplasm. Here and there cystic spaces gave evidence of degenerative changes in the tumors. A moderate number of mitotic figures were present. Prickle cell

evidences of keratinization and epithelial pearls were absent. A fibrous tissue stroma, infiltrated in many places with lymphocytes and plasma cells occupied the areas between masses and columns of epithelial cells. Erosion and ulceration of the surface were present in most of the tumors.

The epidermoid carcinomas were characterized by downgrowths of stratified squamous epithelium, composed in great part of cells of the prickly cell type with intercellular fibrils and areas of keratinization within the tumor, which gave rise to the typical epithelial pearls characteristic of this type of neoplasm. In the connective tissue stroma were areas of lymphocytic and plasma cell infiltration. Erosion and ulceration of the surface were present in both tumors.

Sebaceous Cyst—A cystic tumor of the skin arising from a sebaceous gland. Typical cysts arose from a broad base and appeared as yellowish white rather firm, elevated nodules with smooth nonpigmented surfaces. Some were located in the region of the cilia at the margin of the lid, while others occurred in other parts of the lid. These cysts were sometimes difficult to differentiate clinically from fibroma or xanthelasma.

The cysts were lined with stratified squamous epithelium and contained a material which appeared to be made up of degenerated epithelial cells and fatty debris.

Fig 4—Wall of sudoriferous cyst

Sudoriferous Cyst—A cystic tumor of the skin arising from a sudoriferous gland. Such cysts appeared as translucent, yellowish brown nodules, they arose from broad bases and invariably had smooth surfaces. These tumors transmitted light, a property which served as an infallible differential diagnostic sign.

The cyst lining of low cuboidal epithelium enclosed an optically empty cavity.

Hemangioma—A congenital benign tumor composed of an overgrowth of newly formed blood vessels. There are several types of angioma, three of which were encountered in this series of cases.

Two typical cases of plexiform angioma were seen in infants. In one the tumor had been visible three weeks, appearing as a small, dark red spot on one lower eyelid. It had grown rapidly and on admission, appeared as a dark red, bleeding, ulcerating, granulating nodule approximately 6 mm in diameter. It was attached to the skin by a broad pedicle. The clinical diagnosis lay between angioma and granuloma. The tumor in the other child was larger and was located in the upper lid and forehead, it had the typical dark red appearance. Structurally the tumors were composed of masses of newly formed capillaries or, rather, small endothelial tubes, some of which were apparently solid. An enormous number of mitoses

were present. In one tumor the surface epithelium had ulcerated and the underlying vascular tissue was infiltrated with leukocytes.

In a man, aged 53, with nevus vinosus or so-called port wine stain, there were two small, slightly elevated, dark red tumors in the lower lid which had not

Fig 5—Hemangioma nevus vinosus or port wine stain

increased in size since infancy. Under the microscope the tumor was seen to be composed of many dilated capillaries situated directly beneath the normal epidermis. As was expected in a stationary tumor, no mitoses were found.

Fig 6—Dermoid cyst multilocular

One small cavernous angioma of the skin was seen in a woman aged 20. There were several, deep purplish red, slightly elevated tumors along the margin of one lower lid which, according to the patient's statement, had been present since birth. Microscopically, the epidermis was normal but the underlying dermis and subcutaneous tissues were occupied by large, thin walled, vascular channels.

Fibroma—A benign tumor composed of connective tissue which is believed to originate in the sheaths or connective tissue elements of peripheral nerves. All five fibromas were located at or near the margin of the lid. They were yellowish white, firm, elevated nodules with smooth surfaces and arose from broad bases.

Fig. 7—Molluscum contagiosum

Some were difficult to differentiate clinically from nevi, sebaceous cysts or early epitheliomas. In the one case of neurofibromatosis multiplex (von Recklinghausen's disease) the nodule was located in the subcutaneous tissue of the lower lid, it was soft and the overlying skin appeared unchanged.

Microscopically the fibromas were composed of masses of dense, more or less avascular connective tissue and collagenous fibers arranged in whorls and cords beneath the epidermis. The neurofibroma was similar in appearance but much more cellular and quite vascular, a few medullated nerves were visible in sections stained according to Held's method.

Dermoid Cyst—A congenital cystic tumor formed by an inclusion of dermal tissue along the line of an embryonic fissure. Such cysts may be extremely simple, having a lining of simple stratified squamous epithelium but no glands or hair follicles and are then classified by Ewing and others as epidermoid cysts. More often

Fig. 8—Malignant melanoma.

dermoid cysts are more complex and contain all the elements of the skin, for example epidermis, dermis, dermal glands and hair follicles and even on rare occasions, lymphoid tissue, muscle, bone and other tissues.

Two dermoid cysts, both of which had been present since birth, were seen. One tumor, an epidermoid cyst, appeared as a hemispherical nodule approximately

6 mm in diameter, located at the medial edge of the upper lid just above the canthus. The skin appeared normal and was movable over the tumor. Microscopic examination showed the tumor to be lined with a thin layer of stratified squamous epithelium but hair follicles and glands were not found. The tumor looked much like a sebaceous cyst but was believed to be a simple dermoid on account of its presence at birth and its location in the region of an embryonic fissure. The other, a more complex cyst, was a pedunculated growth approximately 5 mm in diameter located lateral to the external canthus. Its color was similar to that of the skin, to which it seemed to be attached, and its surface was slightly nodular. It might easily have been confused with papilloma on account of its nodular surface and pedunculation. Under the microscope this tumor proved to be a multilocular dermoid cyst. The overlying epidermis showed some large papillae. In the underlying dermis and subcutaneous tissue were one large cyst and several small daughter cysts, each lined with stratified squamous epithelium surrounded by many hair follicles, some of which opened into the cysts. The cysts appeared to be filled with sebaceous material and other debris. An interlacing connective tissue stroma lay in the area between the cysts.

Molluscum Contagiosum—A contagious disease of the epidermis caused by infection with a specific filtrable virus and characterized by the formation of small nodules in the skin. Two such cases were seen. One occurred in a child showing three nodules on the face, one of which was located in the lower lid. This lesion appeared as a small slightly elevated wax-like nodule composed of white seedlike lobules, it had the characteristic central umbilication. The other lesion occurred in an adult as a single nodule of somewhat similar appearance located at the margin of the lid. The clinical diagnosis here lay between papilloma and nevus, since the lesion was single and was located at the margin of the lid, and umbilication was questionable.

Under the microscope these tumors were composed of masses of hypertrophic, swollen, degenerated epithelial cells. The basal or germinal cells were somewhat enlarged and showed a few mitoses. Just outside the germinal layer the cells were greatly swollen and vacuolated and the nucleus was atrophic and pushed to one side by the cytoplasmic inclusion bodies, which were made up of myriads of minute spherical virus particles or elementary bodies. At the apex of the lesion many of the cells were ruptured and desquamating. There was little or no inflammatory reaction in the adjacent tissues.

Malignant Melanoma—A malignant neoplasm supposedly arising from a nevus. This tumor had been present for three years in an elderly man, beginning as a small subcutaneous nodule in the lower lid. The mass had enlarged slowly for two years but during the past year had grown rapidly. At the time of admission the tumor appeared as a large subcutaneous mass in the temporal portion of the lower lid; it measured approximately 2 by 2 by 1 cm. The growth had infiltrated the tarsus palpebral and bulbar conjunctivae and evidently the sclera since ocular rotations were limited. The overlying skin was stretched and had a bluish sheen but was freely movable over the growth. Following removal microscopic examination showed an unusual neoplasm growing wild in a fibrous tissue stroma. The tumor cells, which were arranged in whorls, nests and strands, were spindle shaped with

oval, deep blue nuclei and fairly abundant cytoplasm. A few mitoses were noted. Parts of the tumor were suggestive of basal cell carcinoma and others had the appearance of sarcoma. Aniline blue stains showed no fibrils. Scattered throughout the tumor was a fine granular pigment, most of which was incorporated in phagocytic cells in the stroma but some of which appeared in the tumor cells. This pigment did not give the iron reaction and was believed to be melanin.

Sweat Gland Adenoma—A tumor that had grown slowly for many years was seen in an elderly man. The growth was located at the margin of the lower lid; it measured 4 by 4 by 6 mm, was attached by a broad base and had a smooth slightly pigmented surface. Clinically it was believed to be a nevus. Under the microscope the tumor was composed of alveoli lined

cell nests were separated by a loose connective tissue stroma. No fat was found in the fibers of the orbicularis muscle.

Granuloma—A small rapidly growing subcutaneous tumor appeared at the temporal side of the lower lid in a young woman. There was no history of injury or any other lead as to the possible cause of this growth. The nodule measured approximately 3 mm in diameter and was not tender to palpation and the overlying skin was not discolored. Microscopic examination revealed a dense connective tissue infiltrate, especially in the perivascular areas, with lymphocytes and an occasional plasma cell.

CONCLUSIONS

In a series of 100 consecutive tumors of the lid which were studied clinically and with the microscope eighty-four were of various benign types and sixteen were malignant.

The benign tumors were classified as follows: papillomas 34, nevi 17, sebaceous cysts 13, fibromas 5, sudoriferous cysts 4, hemangiomas 4, dermoid cysts 2, molluscum contagiosum 2, sweat gland adenoma 1, xanthelasma 1 and granuloma 1. Of the malignant tumors fifteen were carcinomas and one was a malignant melanoma.

It is apparently sometimes difficult or impossible to make an accurate clinical diagnosis. Papilloma, nevus and fibroma and at times early epithelioma are easily confused if they are at all atypical in appearance. Molluscum may be difficult to differentiate, especially if the nodule is located at the margin of the lid. A sebaceous cyst may be confused with fibroma or xanthelasma. Fortunately carcinoma is usually easily diagnosed although, in the early stages, before ulceration it may be difficult to differentiate from a papilloma, nevus or fibroma.

ABSTRACT OF DISCUSSION

DR. ARNOLD KNAPP, New York. The authors have presented an excellent survey of the tumors of the lid and I wish to compliment them on the beautiful histologic pictures. In the case of tumors of the lid a mental picture of the histologic nature of the process is a great help to the proper treatment of the condition. It occurred to me that a report of a carcinoma of the meibomian gland may be in place today. This occurred in a woman aged 59 whom I saw in 1926 with a swelling of the upper lid measuring about an inch by half an inch, definitely in the tarsus with the overlying skin not involved and not tender. The conjunctival surface of the lid was definitely reddened, nodular and bulging into the conjunctival sac and there were no glandular involvements. The tumor was removed from the inside of the lid in the manner in which a tarsectomy is performed. Except for a slight recurrence at the temporal extremity four months later the patient had no further trouble from the lid. The microscopic examination revealed it to be carcinoma. A year later a swelling appeared in the preauricular region of that side. This was removed by a general surgeon and required a second operation about nine months later when radium seeds were implanted. Slowly in the course of the next few years the glandular involvement descended along the side of the face and the side of the neck and ultimately the patient developed symptoms of an abdominal tumor from which she died in 1933. One reason for mentioning this case is that at one stage of its development it would undoubtedly have been taken for a chalazion. I feel that many conditions are operated on which are not chalazias and I am ready to confess that I have made this mistake many times. It proves that a microscopic examination is indicated whenever one sees a chalazion-like tumor which is in any way atypical or which recurs.

DR. ALGERNON B. REESE, New York. For comparison with the authors' group of cases I have listed 100 consecutive tumors removed from the lids at the Eye Institute of New York.

Fig. 9.—Xanthelasma. The xanthoma cells appear black.

with cuboidal epithelium. Here and there the basal cells of the epidermis extended downward in finger-like processes into the tumor. The stroma was composed of loose fibrous tissue with a few blood vessels. There were subepithelial infiltrates of lymphocytes and plasma cells. The surface of the tumor was irregular and a small ulcer had formed in one area.

Xanthelasma—A lipid degeneration of the dermis and subcutaneous tissues which while not a tumor sometimes has the clinical appearance of one. This case as is usual occurred in an elderly woman as bilateral yellow, flat, slightly elevated areas at the nasal side of each lower lid.

Under the microscope the epidermis appeared normal and only a few fat globules were found in the dermis. In the subcutaneous areolar tissue were nests or groups of large, slightly granular single or multinucleated xanthoma cells filled with fat; these cells stained only lightly with hematoxylin and eosin but assumed a deep orange color with sudan III. The

epithelioma 28 (basal cell 21 squamous cell 4 basal-squamous cell 3), papilloma 18, hemangioma 11, nevus 8, sebaceous cyst 6, dermoid cyst 5, sudoriferous cyst 5, granuloma 4, adenoma 3, neurofibroma 3, malignant melanoma 2, xanthoma 2, lymphangioma 1, lymphosarcoma 1, teratoid tumor 1, foreign body reaction 1 traumatic inclusion cyst 1. In this series the epithelioma is the most frequent and it assumes greater importance on the lid than elsewhere on the skin because in the treatment by surgery or irradiation a possible disturbance of function must be taken into consideration. This may be in the nature of a defect of the lid margin which may be not only a cosmetic blemish but may prevent proper protection of the eye. In irradiation the danger of cataract is always present no matter how carefully the eye is shielded. In two thirds of the cases the lower eyelid was affected. Even a higher percentage of epitheliomas occur on the lower lip rather than the upper. The reason usually given for the predilection of an epithelioma for the lower eyelid and lower lip is that these are the areas which have the greater exposure to the actinic effect of the sun. Another possible reason is the more frequent irritation to which these parts are subject. Certainly the lower lid is more frequently and more severely involved by blepharitis. Our cases also show, as do the authors, that the basal cell is about five times more common than the squamous cell epithelioma. This is fortunate because as the authors pointed out the squamous cell type may metastasize especially to the regional lymph nodes whereas the basal cell type does not. The authors include the dermoid cysts in their group of lid tumors but these should perhaps more properly be considered orbital lesions. The heading "granuloma" includes three cases which we call for purposes of identification novocainoma. Sometimes following an injection of procaine hydrochloride into the lids for a surgical procedure there occurs over the site of the injection a lump the center of which is necrotic tissue surrounded by granulation tissue with many foreign body giant cells. Various special stains fail to disclose bacteria or any foreign substance. It is assumed, therefore, that the reaction is due to a chemical change. We have had this lesion occur a number of times always in groups and they cease with the use of a fresher solution of procaine. The xanthomas did not resemble clinically or histologically xanthelasma. They were round fatty tumors near the lid margin occurring in patients aged 8 months and 38 years. The teratoid, or composite tumor was at the base of the nose adjacent to the inner canthus. It was encapsulated and contained cartilage myomatous tissue and fibrous tissue throughout which was irregular epithelial masses which formed acini and epithelial pearls. It is often difficult to state the exact nature of a lid tumor clinically.

The Corpus Luteum—The growing follicle reaches full bloom ordinarily about half way between two menstrual periods, in the case of women who menstruate at the usual four weekly intervals. And then its thinned-out wall breaks allowing the egg to escape this process being designated as ovulation. The liberated ovum now is drawn toward the open mouth of the tube by the action of the current produced in the fluid by the ciliary action of the cells of the tube as has been already explained. Let us for a moment leave the egg at the tubal entrance and see what now happens in the ovary. The follicle having discharged its ovum and fluid remains as a collapsed shell. But instead of shriveling up and disappearing this rises like a phoenix from its ashes beginning now a second period of growth during which it assumes a yellowish carrot-like color. For this reason the new structure is called a yellow body or corpus luteum. It increases steadily in size until just before the next menstrual period and as it grows it like the preceding follicle produces substances which are given off into the blood stream and which bring about important changes in the endometrium. These changes complete the preparation of the uterine mucous membrane for the implantation of the egg if it happens to have been fertilized so that such an egg finds its bed nicely prepared when it reaches the womb. In the case of the corpus luteum as we shall see two substances are thus produced to act upon the womb both being necessary properly to prepare the latter for the expected little visitor—Novak. *Emil The Woman Ask.* the Doctor Baltimore Williams and Wilkins Company 1925.

THE TREATMENT OF CHOREA MINOR BY MEANS OF ELECTROPYREXIA

CLARENCE A. NEYMANN, MD

MAURICE L. BLATT, MD

AND

S. L. OSBORNE, BPE

CHICAGO

The therapy of chorea minor, or Sydenham's chorea, has always been empirical and symptomatic. The usual recommendations for treatment have been bed rest, a quiet environment, hydrotherapy and arsenicals especially solution of potassium arsenite, combined with the judicious use of sedatives and hypnotics. Under this regimen the disease, which is self-limiting, usually disappears in from two to six months depending on the severity of the attack and the resistance of the individual. Most neurologists and pediatricians have classified the malady as "rheumatic." While sudden shock, trauma or fright can play a role in bringing on the initial attack, it is generally conceded to be a disease of toxic infectious origin closely allied to rheumatoid infection. Chorea has a definite tendency to recur once

Fig. 1—Tracing in case 17 Aug. 23, 1935, before treatment showing sinus tachycardia. The patient, a girl aged 16, had chorea with rheumatic carditis. The heart rate was 125. T_1 and T_2 are positive. P_2 and I increased. These changes are frequent in rheumatic carditis.

it has attacked an individual and is three as common among females as among males. It is dominantly a disease of childhood and adolescence.

In 1929 Roeder¹ reported having treated a child suffering from chorea with phenyl-ethyl-hydantoin or nirvanol, intending to use the drug as a sedative. The typical nirvanol sickness developed with exanthema and fever. This patient, as well as another treated in the same manner, lost all choreiform movements in a very short time. Following this communication a series of cases successfully treated in a similar manner were reported in this country and abroad.² Gradually the fundamental fact that the fever produced by the drug is the important factor came to be recognized. Sutton³

Sutton and Dodge⁴ and Bateman⁵ employed typhoid vaccine injections for the purpose of elevating the patient's temperature. Their results were excellent. By the use of typhoid vaccine they were able to avoid the malarial sickness which has the disadvantages that it not only takes about two weeks to develop but also usually causes severe illness and occasionally death. Sutton and Dodge fully appreciated the value of fever per se, for they increased the febrile reactions of their patients by enveloping them in blanket packs after the typhoid vaccine injections. Unfortunately, one death

duced by this modality would recommend its use in a disease often associated with acute and chronic rheumatic carditis. We therefore did not attempt to employ electrical hyperpyrexia in chorea until August 1934, at which time electromagnetic induction by means of high frequency currents became a feasible method for the production of fever.

A preliminary report of the results in the first seven cases of this series was made by Neymann⁶ on April 30, 1935. The treatment of eighteen more cases has since been completed. The choreiform movements of all

occurred in their series as a result of this procedure. Before Sutton, Mas de Ayala⁶ had employed Malta fever in the treatment of chorea, and as far back as 1923 von Kern⁷ reported favorable results after milk injections. However, he did not attribute his results to the fever produced by the injections.

Although we believed that the treatment of chorea by means of electropvrexia was desirable and had contemplated such treatment shortly after Neymann and Osborne⁸ first introduced this therapy, there were physical factors that made its application impractical at this time. Treatment with penetrating heat, i.e., diathermy or radiothermy, was extremely difficult because of the constant movement of the children afflicted with chorea. Furthermore, the use of external heat seemed inadvisable to us because we did not believe that the high pulse rate and general physical exhaustion pro-

duced by these twenty-five patients ceased after a series of biweekly fever treatments.

For purposes of clinical classification, the group has been divided into severe, moderately severe and mild

Fig. 2—Sept. 24, 1935, after three treatments. Heart rate 110. T₁ is positive. T₂ slightly positive. A normal electrocardiogram.

types. Nine cases were considered very severe and six moderately severe, ten presented a comparatively mild form of the disease. The average period of hospitalization for all cases was less than sixteen days, and the average number of treatments given was

spent in the hospital by the nine very severe cases was twenty-three, while the mild cases averaged ten. During the period of hospitalization, the child remained in bed without any other medication. The patients were not discharged until all pathologic movements had ceased.

The accompanying table is a survey of our series and the results obtained by treatment. These cases were not selected but were treated as they were admitted to the Cook County Hospital from August 1934 to April 1936. There were nine boys and sixteen girls, varying in age between 4 and 16 years. The tendency of the disease to attack females and young children is shown in the table. The period of observation after treatment now varies between one and twenty months. There have been three recurrences of the disease (cases 11, 19 and 24); one was in a girl and the other two were in boys. Their choreiform movements returned within a few weeks after their discharge from the hospital. Case 19 was probably a nonsuppurative encephalitis rather than a rheumatic chorea and should perhaps not be included in this series. The boy has developed into a behavior problem and institutional care has been advised. None of the other patients have shown a return of their symptoms, though eight of the series had had either chronic chorea or previous attacks of the disease. Hardly enough time has elapsed to make a definite statement except in the first seven cases. Here certainly the disease seems to have been arrested. Two cases (2 and 24) of hemichorea were observed. One patient (case 9) was totally aphasic before treatment was begun, two had a chronic form of the disease and in seven cases the disease was complicated with rheumatic carditis. Only one of these (case 17), however, showed pronounced electrocardiographic changes. Figures 1 and 2

show the electrocardiograph in this case before and after treatment. The improvement after treatment is apparent.

Whenever a child with intercurrent carditis was treated, great care was used not to raise the temperature too high during the first febrile session. In such cases we contented ourselves with a maximum temperature of 39.7 C (103.5 F) lasting two or three hours, during the first treatment period. Three such children complained of difficulty in breathing during the first febrile session. For this reason the treatment was terminated after three hours rather than continued for the usual time. Three days later, treatment was repeated and all these patients finished the course without further difficulty. They were retreated until their twitchings ceased. In our series, just as in that reported by Sutton and Dodge,¹⁰ artificial fever, carefully administered, did not harm patients with rheumatic carditis. We noted a frank clinical improvement after treatment in all the patients with this complication. The fact that we were able to give the usual type of treatment after the initial conservative session and produce the usual type of fever curve seems to us to demonstrate the benign therapeutic action of fever in rheumatic carditis. A typical example of the usual fever curve produced by us in the treatment of uncomplicated chorea is shown in figure 3. The temperature was raised to 39.7 C (103.5 F) as rapidly as possible and maintained between 39.7 C (103.5 F) and 40.6 C (105 F) as a maximum for eight hours.

We ordinarily do not employ temperatures of greater height because in our experience they are unnecessary and some children develop convulsions when a fever above 40.6 C (105 F) is reached. A patient who develops a convulsion during a fever treatment is in potential danger, for the muscle activity in itself may suddenly send the fever to a point at which a heat stroke results. This point is 42.5 C (108.5 F) and above. In case 2 of our series such a convulsion developed during the second treatment when the temperature

Fig. 4.—Portion of the cable under the treatment bag for producing artificial fever by electromagnetic induction.

reached 41 C (105.8 F). The patient was rapidly cooled by uncovering him and blowing air over his nude body with an electric fan. After this observation we usually kept the temperature below 40.6 C (105 F) and no further complications of this type resulted. Another patient developed a transient albuminuria with

10. Sutton, L. P. and Dodge, K. The Effect of Fever Therapy in Rheumatic Carditis Associated with Chorea. *J. Pediatr.* 6: 494-511 (1935).

hematuria during treatment. The therapy was not interrupted, however, and the urine cleared up promptly. Herpes labialis occurred in about 50 per cent of the children treated. Treatments were given biweekly in most cases, and in one or two instances only once a week. We believe that the latter is not sufficiently frequent, certainly it lengthens the period of hospitalization. Some investigators are now treating their patients three times a week or even every day. Such

Fig 5—Treatment for chorea minor with electromagnetic induction using the treatment bag. The coil carrying the current is here placed on the chest of the patient in the form of a pancake.

active therapy will undoubtedly further shorten the period of hospitalization, but we believe that it places too great a strain on the patient's cardiovascular reserve.

As before stated, electromagnetic induction was the modality employed for inducing fever. This method uses a current oscillating at the rate of approximately fifteen million cycles a second. The current is led through a flexible cable, which is placed above or below the patient. The electromagnetic flux produces eddy currents in the patient's body, depending in intensity on the quantity of electrolytes present in the various tissues. The greatest concentration of electrolytes is found in the blood stream, muscles and internal organs and the least in skin and fat. For this reason the deeper lying tissues are heated more intensely than the superficial fat and skin. Thus we have a method which produces heat internally. This method never produces burns when properly applied.

For the purpose of heat insulation, the patient is placed in a treatment bag similar to that used for outdoor sleeping. The cable carrying the current is formed into a pancake coil and rests over the patient's chest and abdomen or under the patient's back shaped as an elongated loop extending from the shoulder blades to the middle of the calf. With either method, the cable carrying the current is placed outside the bag. About 2½ inches of heat insulating nonelectrolytic material, such as blankets, cloth, kapok, wool or cotton, must be placed between the cable and the patient. After the desired temperature of 39.7 C (103.5 F) is reached, the current is turned off and the temperature usually coasts a degree or a degree and a half Fahrenheit higher. A pyrometer couple or thermocouple connected with a pyrometer may be inserted in the rectum after the current is turned off. This lightens the labor of the personnel. Figures 4 and 5 illustrate the treatment.

If available, an air conditioned cabinet (fig 6) instead of the treatment bag may be used to maintain the temperature during the entire treatment. The advantages of such a cabinet are twofold, the patient may move his extremities freely and may change the position of his entire body within the machine. In treating children, who complain less than adults during electropyrrexia, these advantages are partially outweighed by the cost of the apparatus and the time spent in training necessary personnel. We wish to stress the point that the cabinet is never used to produce fever but only to maintain it. In this cabinet the air saturated with enough water vapor to produce a humidity of from 85 to 95 per cent, is circulated at a rate of about 250 cubic feet a minute. The temperature of the air can be regulated to vary between 35 C (95 F) and 45 C (110 F). This air, with its comparatively low temperature and high humidity circulating at the rate prescribed will maintain any desired febrile level when that degree of temperature once has been attained by means of electromagnetic induction. The atmospheric conditions within such a cabinet can be likened to those encountered in the sweltering tropics preceding a down-pour of rain. These conditions do not produce the high pulse rates described by Benson¹¹ and by Phillips and Shikany¹² caused by the overheating of the surface of the skin. The strain on the cardiovascular reserve is therefore lessened.

Attention to the details of nursing care is essential. The patient is not permitted to have breakfast before the treatment. He is given a cleansing enema before being placed in the bag or cabinet. During treatment fruit juices with lactose added, water and, in case of complaint of hunger, milk may be given. All liquids should have enough salt added to form a saline solution of 0.6 per cent. This will replace at least part of the

Fig 6—The treatment of chorea minor by means of electromagnetic induction. The patient is placed in an air conditioned cabinet having the temperature of from 105 to 110 F with a humidity of from 85 to 95 per cent. The cabinet is used to maintain the fever after this has been produced by electromagnetic induction.

sodium chloride lost by perspiration. Convulsions, a decrease in respiratory rate to less than 12 per minute, cyanosis or an increase of the heart rate to 160 per minute or more are indications for the immediate cessa-

tion of treatment. Complaints of pain around the heart and shortness of breath are likewise indications for terminating the session if the patient is one with an intercurrent rheumatic carditis.

Since the preliminary report of Neymann in April 1935, reports on thirty-one other cases of chorea treated by artificial fever produced by physical agents have appeared in the literature.¹³ Twenty-eight of the thirty-one were reported as recovered or greatly improved. About 20 per cent showed a return of choreiform movements. The results herein reported are more satisfactory. All our patients recovered directly after treatment, and only three, or 12 per cent, showed a recurrence of their former symptoms. We believe that this is due to the fact that all treatments were individualized. This was possible because of the ease with which electromagnetic induction could be applied and the fact that the amount of electric current, the heating medium, could be instantly controlled.

SUMMARY

1 Twenty-five cases of chorea were treated by artificial fever produced by electromagnetic induction.

2 In all cases, the choreiform movements ceased promptly.

3 The average period of treatment and hospitalization was sixteen days, an average of four treatments were given each patient.

4 The chorea recurred in three children.

5 Electropyræxia is not contraindicated in rheumatic carditis complicating chorea.

6 In contrast to devices dependent on external heat, electromagnetic induction seems to us to be a superior method for producing therapeutic hyperpyrexia.

ABSTRACT OF DISCUSSION

DR. MAURICE L. BLATT, Chicago. The criteria of a treatment are dependent on the necessity for its use and on its safety. In this series of cases, its safety was apparently well proved. The complications commonly found in chorea did not appear in increasing numbers, nor were the complications already present aggravated by the institution of hyperpyrexia with electrical induction. The treatment, however, is not a simple one. It is not the type of treatment that one would recommend for the general use of individuals not experienced in the handling of such apparatus. Dr. Neymann's previous experience with hyperpyrexia in the treatment of more chronic diseases, however, warranted our attempting this series of cases. In a general hospital such as the Cook County, the number of days of hospitalization is a factor of considerable economic importance. In our previous series of cases, we found that approximately five to six weeks with nursing care and sedation was the usual period of hospitalization necessary for these patients. In addition, the incidence of endocarditis or rheumatic carditis was a factor of some consequence since many of these patients returned to us at a later date with cardiac decompensation or with acute exacerbation of an endocarditis the primary occurrence of which was recorded during the first choreiform attack. We have examined these cases since their discharge and have found no manifestations of endocarditis not recorded at the time of entrance or the time of discharge from the hospital. It has seemed to us that if we could shorten the course of the disease process associated so frequently with endocarditis we might

cut down the number of cardiac cases that come back to us at a later date. In this series we were able to shorten the period of hospitalization. We did so apparently without harm to any of these patients. We probably prevented the occurrence of a number of cases of rheumatic carditis and to date but two cases of chorea have recurred.

DR. C. A. NEYMAN, Chicago. We believe that our efforts have been worth while because we have had no deaths because if anything, the rheumatic carditis was improved after treatment and not aggravated and because the patients seemed after months of treatment, to be in better general physical condition than one would ordinarily expect especially in the patient who had developed a more or less chronic recurring chorea.

OSTEOMYELITIS OF THE FRONTAL BONE

NOTES ON THREE CASES

H. P. MOSHER, M.D.

BOSTON

As the title indicates, I am not writing a systematic paper or one that attempts to cover the subject of osteomyelitis of the frontal bone in any way approaching thoroughness. I shall pick and choose perhaps from old habit leaning toward the dramatic, stressing the points from which I have learned something and those which strengthen convictions which have been gradually and somewhat laboriously built up in my mind on this subject during the past five or six years. During this time I have seen, I will not say, the full light but some light.

In two of the cases which I am to comment on large portions of the frontal bone were removed in one piece. One measured 2 by 2½ inches, the other 3 by 2½ inches. It was possible, therefore, to get large sections for histologic study. Before, I have had small pieces taken from known positions in the frontal bone and drew my conclusions as to how far the infection spread from them. The large histologic sections which I am reporting on here, many of them serial sections, made it possible to trace the infection by continuity until it disappeared, and to see the routes by which it traveled. The conclusions stated in my earlier paper have been amply confirmed. I shall present the histologic observations of the new specimens as briefly as possible. From the practical standpoint, they are the most important facts that I have to present.

I was not the operator in any of the cases. In each from time to time I acted as consultant. The operators' names, to use theatrical language, are given in the order of their appearance.

SUMMARY OF CASES

CASE 1 (surgeons, Drs. P. E. Meltzer, R. L. Goodale and H. G. Tobey).—A woman aged 21 received a black eye on the left while wrestling. One week later while riding in an automobile, she noticed a swelling in the middle of the forehead. It became painful ten days later.

On admission to the hospital there was an elliptic swelling in the median line of the forehead which was fluctuant and painful on pressure. The patient's chief symptom was severe headache.

At operation the median skin incision evacuated a large amount of pus from a pocket under the skin. The central

Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

This article on account of lack of space is abbreviated in *THE JOURNAL* by the omission of numerous illustrations. The complete article will appear in the Transactions of the Section and in the author's text.

portion of the frontal bone for an area about the size of a 50 cent piece (30 mm) was bare of periosteum and moth eaten. The surrounding bone for 1 inch laterally and up to the hairline appeared normal. The periosteum was intact but when the bone was drilled, pus escaped from the diploe. With the electric drill, an elliptic area of bone measuring $2\frac{1}{2}$ by 2 inches was outlined and removed. The bone was adherent over an extradural abscess, and the dura presented many granulations. There was no evidence of a cerebral abscess.

The patient's convalescence was uneventful. About six weeks later, Dr. Kazanjan did a plastic operation for closure of the flaps. The lower end of the midline incision had to be opened later and wicked for a short time.

Two months after her discharge and four months after her original illness, the patient was readmitted.

The edges of the bone defect showed no osteomyelitis. She now had all the signs of a frontal lobe abscess. The first brain exploration was negative. At the second an abscess was found deep in the left frontal lobe.

The choking of the disks was especially marked, reaching 6 diopters in each eye. The other cardinal sign of increased intracranial pressure, namely, the pressure of the spinal fluid was always high and rose at one time to 600. At this time a re-investigation of the abscess gave no further pus. Tapping of the left ventricle gave neither pus nor fluid. The patient then became thoroughly septic. She had two anginal attacks, a pneumonia of the right upper lobe and a question of a mesenteric infarct.

The blood culture was never positive. The organism from the brain abscess was *Staphylococcus albus*. The white count varied from 13,200 on admission to 9,850. The fields could never be taken satisfactorily.

The autopsy showed multiple abscesses in the right frontal lobe which had not been found. On the left there were no abscesses. The abscess which had been found on the left had been extruded. About three fourths of the left frontal lobe had sloughed away and the right was filled with abscesses.

There was no meningitis.

I interpret this case as one of localizing osteomyelitis which started after trauma. The exposure on the automobile ride probably played a part in hurrying things along. It has been known for a long time that after a Killian frontal sinus operation an automobile ride with the wind shield up is very liable to cause a blow up in the operative wound.

The patient was operated on radically and she made an uneventful recovery except for a slight infection at the lower end of the median incision after the plastic operation. This was found to be due to the fact that the right frontal sinus had not completely filled with granulations. This happening occurred in another case not included in this series. It is of no use, therefore, to do a plastic operation until the sinus cavities are fully obliterated by granulations.

I might add at this point that some years ago I stated it was my belief that the surest way to obliterate a frontal sinus is to remove both the anterior and posterior walls as we have done for the past five years almost as a routine in cases of osteomyelitis originating in a septic frontal sinus. At present there is no sure way of obliterating a frontal sinus. In carrying out this procedure, the floor of the sinus is not removed and only a minimum enlargement of the nasofrontal duct is attempted. The ethmoidal cells are dealt with in the customary way.

The most reassuring thing about the case is that the osteomyelitis was cured at the first operation.

The other points which I wish to comment on are as follows. The large bone removal allowed the opened brain abscess to come to the surface and to slough off. Frontal lobe abscesses when opened I feel, have a tendency to come to the surface more readily than abscesses in other localities.

The removal of a cone of brain tissue down to the abscess by the diathermy knife, as was done in this case and the removal of a part of the abscess capsule by the same method I have found an improvement over older procedures.

The point in the case which bothers me the most is the time of the plastic closure, i.e., six weeks. This seems to me to be too short, especially as there had been some infection in the median incision after the plastic operation. I feel that three months would be a safer time.

In making a trephine opening in the frontal bone either to outline the bone flap or for diagnostic purposes, if pus wells up from the diploe in quantity there is an extradural abscess. There may be an extradural abscess even if there is no pus in the diploe, therefore all diagnostic trephine openings should be carried through both tables of the skull to the dura. Extradural

Fig 2 (case 1)—Bone defect on reentry of patient to hospital. There is no evidence of osteomyelitis.

abscesses are so common that one should expect them and look for them, and not consider them as a rare complication.

In this case there was thrombosis of the superior longitudinal sinus. There is every reason why this should happen in osteomyelitis of the frontal bone and I believe that it often occurs without being recognized. I have known it to be present in several other cases. The emboli probably came from the sinus. When a thrombus is present it must greatly increase the septic load of the patient even without thrombi. Unless, however, the clot goes well back and is large enough to cause pressure on the motor areas of the legs which about on each side of the sinus, the classic leg symptoms do not appear. They were not present in this case although the sinus was thrombosed to the torcular.

Incontinence of urine was a prominent symptom during the patient's second hospital stay. This is given by some writers as characteristic of a frontal lobe abscess. Dreams and hallucinations are given as further symptoms. The patient did not have either of these. She did, however, develop a great change in character.

and a marked loss of memory. A change in character also is supposed to be peculiar to frontal lobe abscess. It has been noted, however, in abscess of the other lobes. Dr. Schall had such a case after a cerebellar abscess. A clinging vine type of wife, on returning from the hospital, changed to the exact opposite and proceeded to beat up her husband.

It was learned quite a few years ago in one of Dr. G. H. Tobey's first cases that a bacteriophage dressing keeps the operative wound cleaner than any other. It was being used in this case. After the brain abscess on the left was found, the temperature remained at about 100 for ten days, when there was a sudden rise and the patient's condition became very poor. It so happened that Dr. Lynch, the house officer in charge of the case, was at our regular Friday evening meeting at the medical school, and the patient's condition was reported to him by telephone. One of the papers

Fig. 9 (case 2)—Enlargement of diploetic vein from infection. See figures 7 and 8.

abstracted that evening was the report of a case of osteomyelitis of the skull. It was a long drawn out affair with many complications and many operations. I never read a more dramatic report. A bacteriophage was used intravenously. The patient recovered, and much of the credit of the recovery was given to this procedure. I suggested that the treatment be tried in our case. This was done and the change for the better in the patient's condition seemed almost a miracle. We were actually stunned by the improvement and almost asked one another if the patient was going to get well.

As was stated in the summary there were many complications, a pneumonia, two anginal attacks and a question of a mesenteric thrombosis. During these complications the intravenous use of the bacteriophage was persisted in, seven injections in all being given. Finally it was powerless to combat the general sepsis; the temperature rose again, and the patient died in twelve hours.

CASE 2 (surgeons Drs. V. J. Kelley, P. E. Meltzer, R. L. Goodale and L. A. Schall)—A boy aged 14 ran the whole gamut of the complications that can occur in connection with an infection of the ethmoidal labyrinth and the frontal sinus. He started with an infection of the left frontal sinus and

the ethmoidal labyrinth. This was aggravated by swimming and he entered the hospital with the left eye closed and pushed down and out. There was marked swelling of the left side of the forehead and left temporal region and marked tenderness in the left temporal fossa. A Lynch operation was done on the left frontal sinus, and the left ethmoidal labyrinth was everted. Pus was found in the orbit and in the ethmoidal labyrinth.

The swelling promptly extended to the right frontal sinus and an external operation was done on both frontal sinuses. The bone at the outer angle of the left frontal sinus was found to be necrotic. The patient did poorly.

The roentgenogram showed an extension of the osteomyelitis laterally toward the lower outer angle of the frontal bone and a bone flap measuring 2 by 2 inches was removed at this place.

Because the spinal pressure rose to 700 and there was a beginning choking of the disks, an exploration for a frontal lobe abscess was performed five days after the third operation, and an abscess was found.

About a month later a small fluctuant swelling appeared (1 by 1 cm.) on the forehead an inch beyond the hairline. The roentgenogram showed the presence of osteomyelitis as far as the coronal suture.

At operation a large abscess was found under the local swelling. The bone was necrotic beneath the abscess and pus pulsed through a hole in the bone. A bone flap measuring 2½ by 3 inches was removed. This extended from the old bone edge to just beyond the coronal suture and 1 inch beyond the median line to the right.

The wound was very dirty but cleaned up under treatment with bacteriophage.

In a few days over a month, the patient died. Her second hospital stay was two and a half months. Autopsy revealed osteomyelitis of the frontal bone, meningitis and multiple brain abscesses (frontal lobe).

In this case swimming, I believe, was a decided factor in the extreme infection. Our worst cases of frontal sinus infection and osteomyelitis have followed swimming. We had three such cases in a row.

Another point in connection with this case, a well known point now, is that the roentgenogram was not positive for bone necrosis until nine days after the external swelling appeared.

One usually thinks of osteomyelitis as advancing upward on the front face of the frontal bone instead of extending to the outer angle and progressing from there. In this case however the greatest swelling and tenderness were in the left temporal fossa and a large piece of infected bone was removed from this locality. From a few cases which we have had I have learned to be suspicious of the outer angle of the frontal sinus and of the external angle of the frontal bone. In what I like to call a full operation the bone flap should extend laterally far enough to reach the outer limit of the frontal sinus and at least encroach on the anterior limit of the temporal fossa.

The subcutaneous abscess which was the last complication could be seen to have its origin in a thrombosed diploic vein. It was striking to see how far the infection traveled by way of the vein from the original source of the infection. It was easy to see in the specimen how an abscess originating in this way could extend both inward and outward, causing both a subperiosteal abscess and an extradural abscess.

CASE 3 (surgeons, Drs. M. H. Lurie, F. E. Garland, A. H. Kazanjian, G. H. Poirier, L. E. White and E. B. Lovett)—A woman aged 26 following a cold for ten days had swelling and tenderness of the left frontal region with edema of the forehead. She had one convulsion. The left half of the forehead bone was removed from the upper limit of the edema to the frontal sinus the front wall of which was removed.

Six days later the left ethmoid was excrated. There was pus in the ethmoidal labyrinth. At the first operation there was a rupture in the dura. At the second operation a small abscess was evacuated through the dural tear. Six days later another abscess was found 2 cm below the first one.

The headache and vomiting persisted and eight days later the herniated brain tissue was removed and a large opening was made into the abscess. The recovery from the operation was slow. In the right eye there was 1 diopter of choking of the right disk and three fourths in the left. The choking slowly disappeared.

In the next three months three sequestrums were removed from the right edge of the bone defect. Then the patient had a convulsion and was admitted to the hospital. The next day she had three convulsions. No more convulsions occurred and five days later she was discharged to the neurologic clinic.

About two years later she had ten convulsions, became unconscious and was admitted to the hospital in coma.

On the day after admission she was operated on. An L shaped flap was turned up by following the old incision. At the lower inner angle of the wound a cystic swelling was present. This was opened and found to contain clear fluid which proved to be sterile. Two days later the left frontal lobe was explored for brain abscess. No abscess was found. In four days the patient was rational and in ten days she was up in a wheel chair.

A month later a plastic closure of the wound was attempted. Following this, the center of the flap sloughed.

Again a month later, Dr. Kazanjian performed the second plastic operation transplanting a piece of whole skin to fill the defect.

The patient was discharged April 14 1936.

This young woman must have a charmed life. I have seldom seen a patient as sick as she was get well. In the four years that she has been coming to the hospital, she has been admitted five times and had nine operative procedures. She seemed to specialize in convulsions.

At no time was the pressure of the spinal fluid high, and the choking of the disks was only moderate.

The important point about the case is that the patient had a complication which may occur, but seldom does, in any healed case of osteomyelitis, namely, an arachnoid cyst. This was accompanied by coma and many convulsions. I have known such a cyst to follow a radical mastoid operation, but this is the first time I have seen it in a case of osteomyelitis. The bone removal included only half of the frontal bone. The bone flap evidently was not large enough, because later two small sequestrums and one large one were removed from the left edge of the bone defect. The bone flap should have included the right half of the frontal bone as well as the left.

THE INCISION

Four types of incision have been used to expose the frontal bone, including a U shaped incision with the base down, a U shaped incision with the base up, and a median incision from the hairline to the root of the nose joined by a horizontal incision paralleling each eyebrow. The fourth incision, advocated by von Eicken is a right angular incision with the point of the angle at the external angular process of the frontal bone. I prefer a central incision meeting a horizontal incision above each eyebrow. The main point is to get a thorough exposure of the whole front face of the frontal bone. Timid incisions breed timid surgery.

The U shaped flap which turns down does not give full vision of the wound postoperatively, or full drainage. The U shaped flap which turns up should give better cosmetic results. It does not cover the edges of the bone defect well. I am watching one case in

which this form of flap was used and cannot give a positive opinion about the flap until the case is further along. The question is what will be the fate of the bare bone.

The right angular flap of von Eicken does not appeal to me because it limits the exposure of the frontal bone especially at the opposite external angular process of the frontal bone. One of the things, and I have mentioned it before, which I think that I have learned about these cases of osteomyelitis is to watch the external angular process of both sides.

THE REMOVAL OF THE BONE FLAP

Marking out the bone flap by trephine holes made by an electric burr is the quickest and most craftsman-like method. One worries at first about getting the bone flap free from the superior longitudinal sinus. Experience has shown that slow dissection will readily accomplish this without tearing the sinus.

When, however, the dissection goes hard owing to a marked bowing of the frontal bone and the large size

Fig. 13 (case 3)—Cyst after evacuation and filling with iodized oil.

of the bone flap, if half of the bone flap is sacrificed up to the longitudinal sinus, the periosteal elevator can get a straight shot, the operator can see better what he is doing, and the bone flap can be more easily and safely freed from the sinus.

HISTOLOGIC EXAMINATION OF THE BONE SPECIMENS

In the first specimen the bone was taken adjacent to the original source of infection, namely, the frontal sinus, and its vertical diameter extended some 2 inches from the upper rim of the sinus. The second specimen was taken at a distance from the original source of infection, that is, at the top of the forehead, and consisted of a bone flap measuring $2\frac{1}{2}$ by 3 inches. It was perforated in the center by a necrotic area, which connected superficially with a subperiosteal abscess and internally with an extradural abscess.

In the first specimen, in what might be called the more acute case, the marrow spaces were crowded to overflowing with large and small lymphocytes. The majority of the marrow spaces were markedly infected and many of them contained actual abscesses. There was some fibrous tissue, but it did not predominate. Infected vessels were found making their way to the

surface of the bone, both externally and internally. The infection broke through the inner table more often than the outer table. The current of the infection, so to speak, seemed to be more inward than outward. There was some new bone on the surface of this specimen next to the dura. The inner surface of the new bone was covered with a layer of infected blood clot and in places with infected granulation tissue.

The impression which the bone gave was that the majority of the marrow spaces were acutely infected.

Fig. 14—Various types of flap. The author prefers the third.

as shown by the great increase of the cellular elements, especially the small and large lymphocytes, and the large numbers of polymorphonuclear leukocytes. In this case the osteomyelitis was circumvented and cured by operation.

In the second specimen the bone flap was removed at a distance from the original source of infection after two other bone flaps had been removed and the case had been running a much longer time than the first one. In this second specimen there was actual abscess formation in the marrow spaces near the necrotic area in the center of the bone flap. There were a few scattered abscesses in other parts of the bone, but the predominating picture was that of fibrosis of the marrow spaces.

On the inner surface of the bone flap there was a longer and larger layer of new bone. Through this many infected vessels ran to the dural surface. Again there was an infected blood clot between the dura and the bone, and the vessels in the fibrous tissue that connected the dura and the under surface of the skull were often infected. Again the impression was that the greater current of the infection was inward. The extensive fibrosis of the marrow spaces suggested that the infection for the greater part had been conquered and walled off except along the track of the infected vein which led to the necrotic perforation in the center of the bone flap. Infection was found to extend to the edge of the bone in all directions.

The first specimen, therefore, shows the acute fulminating type of infection and the second shows bone in which the infection had cleared up for the most part and the marrow spaces had been obliterated by fibrous tissue. The main channel by which the infection spread in the second specimen was by way of a diploetic vein.

CONCLUSIONS

It is obvious that I am not reporting these three cases as favorable results because two of the patients died. My purpose in reviewing them is to record a number of facts which I learned from them. Also, reporting the cases gives me an opportunity after a silence of three years to say my say again on the subject of osteomyelitis. Three years, I maintain, is a modest and commendable period of silence. Others of my audience might well imitate me in this respect. In reviewing all the cases which we have had at the infirmary, espe-

cially those of the past five years, our operative results have been progressively better, and better in direct proportion as the operations performed were systematic and radical.

I feel even more strongly than I did in my original paper of three years ago that the edema of the skin of the forehead is a rough guide to the extent of the bone and periosteal infection. Further, as was pointed out in that paper, if there is actual bone necrosis the bone is infected without necrosis for an inch to an inch and a half beyond the necrotic area. Bone necrosis does not occur until seven to ten days after the pitting edema appears, and the x-ray is not positive until necrosis appears. Examination of the bone specimen removed in two of the cases just reported showed that the infection spreads along the inner surface of the bone as well as by the diploic veins. When the infection spreads by way of a diploic vein it may localize at a point far from the original source of infection. When it does so localize, the pus tends to work both inward and outward, giving either a subperiosteal abscess or an extradural abscess or both, with a destruction of the bone between the two. When a case has lasted two or three weeks the operator should expect to find one or both of these conditions.

The histologic examination of my specimens shows in addition that the infection may spread by way of an inner layer of new bone which is formed between the skull and the dura. The small veins which run in the new bone are often infected and there are numerous hemorrhagic clots which also are infected. Further the infection spreads by way of the fibrous tissue which covers the new bone and which binds the inner surface of the skull to the dura.

The operator who is doing his first operation on osteomyelitis of the skull should expect extradural abscesses as a matter of course. In fact, he should expect more than this, he should be on the lookout for a subdural abscess or a brain abscess. The brain abscess, if present, is usually found later or comes later as a complication, but it is always round the corner, and should be watched for even at the first operation.

The more I see of osteomyelitis of the frontal bone, the more I feel that the whole face of the frontal bone should be removed as a routine from the hairline to the eyebrow. Preferably, it should be removed in one piece. However if the patient is in poor condition and there is an area of necrosis, it is justifiable to work from the necrotic area outward, removing the bone for an inch to an inch and a half in all directions from the necrotic area. I believe further that both frontal sinuses should be opened, and the anterior and posterior walls of each sinus removed. I feel strongly that the lateral limit of the bone flap on each side should be at least the outer angle of each frontal sinus or, better, the outer angular process of the frontal bone on each side. The objection to this extensive removal is the deformity. It has been proved that fully 90 per cent of this can be corrected by modern plastic surgery. Therefore the surgeon should not allow himself to be halted by the question of deformity. If he does he will lose most of his cases of osteomyelitis of the skull.

Fig. 16—Drill holes for removing the frontal bone in one piece.

ABSTRACT OF DISCUSSION

DR ERNEST SACHS, St Louis I have had the opportunity of seeing a good many cases of osteomyelitis of the skull in the last twenty-five years, and the one conclusion that I have come to is that the best way of treating them is to be conservative. Drain the superficial abscess and wait for the skull to sequestrate and then remove the sequestrums. I am sorry that I have to disagree with Dr Mosher but in my experience the cases in which large fragments of bone have been removed have been the cases that have ended as a rule disastrously, just as his have. The most common complication of osteomyelitis of the skull is a brain abscess. One of the things about which neurologic surgeons feel very strongly is that in dealing with brain abscesses in the presence of an infected skull, whether it is the mastoid or the frontal region, it is extremely important to drain the abscess through a clean field and not to go through an infected field. I believe the principle of going through an infected area is not sound surgery. One should go through a potentially clean area. That may be an extremely difficult undertaking when an extensive osteomyelitis is present, it may be occasionally even impossible. But if the conservative method is used and healthy areas of bone are not opened but sequestrums are allowed to separate and then removed the field is gradually cleaned up and better results will be obtained.

DR JOHN J SHEA Memphis In the *Laryngoscope* (43 153 [March] 1933) Mosher and Judd presented a valuable contribution on osteomyelitis in which they delineated its pathology. The authors felt that the edema of the skin and the soft tissues of the forehead roughly furnished a practical guide to the extent of the bone infected and the limits necessary to be removed. Today Mosher's paper on the clinical aspect of three cases demands a thorough study of the manuscript in order to learn the many lessons that it contains. Osteomyelitis of the frontal bone is a progressive disease and its surgery must be timely and radical. Formerly it was a fatal condition but with bolder cranial surgery and the utilization of immunization successful cases are constantly being reported. If a census should be taken of this audience many cases never published would be reported. The bacteriology of osteomyelitis of the frontal bones is the same as osteomyelitis of the long bones. This severe complication may follow any operation simple or radical a suppurating sinus or may occur spontaneously with or without trauma. Usually it occurs whenever the diploe has been opened and exposed to an infection against which sufficient immunity has not been established. The diploe of the frontal bone is spacious in the growing skull which explains the rapidity of its spread in young adults. The earlier the osteomyelitis occurs after an operation or injury the more likely is it to be serious and rapid in its destruction. I agree with Dr Mosher that roentgenologic studies are misleading for the pathologic changes are more advanced than revealed in the films. Dr Mosher calls attention to the frequency of extradural abscesses. In two cases presented to the Southern Section of the American Laryngological Rhinological and Otolological Society in 1928, I called attention to the tendency of the infection to travel upward to the site of the anterior fontanel and then extend inward to form an extradural abscess. The operative procedures are carried out with greater ease under local than under general anesthesia.

DR O JASON DIXON, Kansas City, Mo The knowledge that this was a serious disease and that other men before me failed prompted me to try a more or less cowardly procedure. To my surprise I found that by not operating I got better results. I watched these patients go away and come back in a year some of them in two years and under a local anesthetic have a small sequestrum removed. The radical procedure is a very frank admission of the lack of understanding of the true nature of the disease. Not much is known about the pathology of osteomyelitis of the skull. Certainly thrombosis is nature's protective mechanism against the systemic spread of an infection and is not always a fatal or a bad sign. By no means is it an indication of necrosis. Pricking one's finger with a splinter never killed anybody because the splinter was left in. It kills from the onset with the spread of the phlebitis and the reaction that occurs immediately following the onset of the injury. If one does not succumb the foreign body may stay in for weeks or months or years without any harm. Physicians must have the patience to stand by and help the patient a little. I am convinced that it is unfair to criticize anything

about this procedure unless one takes the entire responsibility, and to be a good critic one must be bold enough to go ahead and handle the entire problem. As Dr Sachs so well emphasized, the brain abscess is the major problem. The patient must be viewed as a whole and not through a microscope or a slide or the x-ray film. Fortunately for me I did not diagnose my early cases early because I didn't think about it and I didn't get the x-ray picture. It is just as well not to find out the diagnosis early. Swimming is the chief etiologic factor. I have had so many cases from Pittsburg, Kan., due to swimming in the strippet mines that there must be something to that. Trauma plus infection is the major factor. The physician must have the courage to stand by and support the patient and let him fight his first infection and then to remove the sequestrums as they occur, preferably under local anesthesia.

DR JOSEPH E J KING, New York I favor the opinions expressed by Dr Mosher regarding the complete extirpation of the involved bone in osteomyelitis of the skull. I did not know that the conservative removal of sequestrums was advocated by any one. Drs Mosher, Furstenberg, Naffziger, Fincher and others have reported series of successful results after complete extirpation. I have had about eight such cases at Bellevue Hospital, the Manhattan Eye, Ear and Throat Hospital, and the Jersey City Medical Center. Furstenberg states that regeneration of bone takes place between the dura and the pericranium in about two years and fills the cranial defect so that a cranioplasty is not necessary. Naffziger told me that he has removed a block of involved skull *en masse* and has later reinserted the piece of skull which remains intact and takes well. Before knowing of Naffziger's work I removed a rather large piece of involved bone from the left parieto-occipital region in a case of metastatic osteomyelitis secondary to a lung abscess. As yet the piece has not been reinserted for the reason that a sufficient amount of bone was not removed and the infection extended around the patient's head, requiring more operations. At the present time an enormous amount of bone has been removed but the patient is perfectly well, is up and about the hospital and works in the ward. I am inclined to agree with the speaker who stated that some cases of osteomyelitis of the frontal bone result from certain types of operative procedures done on the frontal sinus. Nevertheless when these cases occur I think the best results will be obtained from complete extirpation of the infected bone. I turn down a scalp flap with all the soft parts, exposing the skull. The portion involved is completely removed and the frontal sinus is cleaned out. Gauze packings wet in diluted solution of sodium hypochlorite or a solution of azochloramid are placed over the dura, and the scalp flap is returned to its position and loosely sutured. Instillation of the solution is done for six days, at which time under tribrom-ethanol anesthesia the gauze is removed and replaced and again taken out on the tenth day. The flap is again returned to its position and sutured an opening being left for packing the frontal sinus. These cases have recovered nicely. I therefore am heartily in accord with the opinions of Drs Mosher, Naffziger and Furstenberg.

DR HARRIS P MOSHER Boston I never expected a neurologic surgeon to agree with me. He is decided in his opinion, and I am decided in mine, and I will let time settle who is right. Dr King has put the idea as I should like to have it put. He does a more extensive operation than I ever dared to do, not any more extensive however, than Furstenberg has done. The latter is one of the foremost of the brain surgeons of this country. His support is all that I ask. I rest my case with this statement. Until we began a systematic and a thorough operation and clung to conservative treatment we had very disappointing results. It is only since we have reversed our steps that we have begun to get results which were in any way satisfactory. They can be better. Some men seem to feel that their results are all that possibly could be desired but I respectfully doubt it.

Canned and Raw Fruits—In canned grapefruit and in canned tomatoes the high vitamin C value is excellently conserved. These therefore, rank along with the raw citrus fruits and their juices among the richest sources of vitamin C. Not far below them in this respect are raw ripe bananas and some varieties of apples.—Sherman, H C. Food and Health New York, Macmillan Company 1934

PERITONITIS DUE TO BILE AND TO LIVER AUTOLYSIS

HENRY N. HARKINS, M.D., PH.D.

PAUL H. HARMON, M.D., PH.D.

AND

JEANNE E. HUDSON, S.B.

CHICAGO

Bile peritonitis is a clinical entity due to the action of escaped bile on the peritoneal surfaces that is probably more common than has been realized. Eliason and McLaughlin¹ report that perforation of the gallbladder occurs in from 1 to 3 per cent of all cases of biliary disease. These figures were based on a study of more than 7,000 cases of gallbladder disease. It has also been recognized² that bile peritonitis may occur in the absence of demonstrable perforation of the biliary system.

Once the importance of this hitherto rarely recognized condition was demonstrated numerous experimental studies on the mechanism of death in bile peritonitis were made. These observations include the work of Horrall and others³ and center chiefly around the postulates that toxic action and anaerobic bacterial invasion are the chief two lethal factors in bile peritonitis. From other data⁴ similarly obtained by experiment, we have advanced the idea that secondary shock (in the sense of decrease in volume of circulating fluid) is one of the most important lethal factors in this condition. We fully recognize that there are substantial differences between experimental and human bile peritonitis. However, since the theories of the previous workers were obtained by experiment, refutation of these theories might come from similar experiments. It is after this that application of the theories to patients can be made.

No attempt will be made at this time to present proof against the toxic or bacterial theories of death in bile peritonitis, but a brief outline will be given of the positive evidences for the role of secondary shock in this condition. The presence of secondary shock is significant because its therapeutic implications are clear.

Dogs under general anesthesia were used in all experiments. The peritonitis was produced by the intraperitoneal injection of usually 5 cc per kilogram of body weight of either 10 per cent bile salt solution or whole gallbladder bile. The animals were then observed until death, a matter of usually five to twenty-three hours later.

The most striking result of the biliary action was a gradual but profound lowering of blood pressure (chart 1) with a markedly lowered bleeding volume. Accom-

panying this fall in blood pressure was a marked concentration of blood in all of thirty-two dogs observed and in three instances the hemoglobin rose to the extreme values of 177, 178 and 190 per cent respectively. Hematocrit determinations were proportionately elevated. Increase in the blood nonprotein nitrogen content was found in agreement with that previously reported by Ziegler and Orr⁵ and others. Haden and Orr⁶ had previously found that autolyzing liver in the abdominal cavity produces no change in the blood chlorides even with a very great increase in the urea and nonprotein nitrogen.

As the peritonitis developed there was an enormous effusion of blood-stained fluid into the peritoneal cavity. This fluid was not a mere transudate but clotted spontaneously and was shown to be chemically similar to blood plasma in total protein, sugar, sodium chloride and nonprotein nitrogen content. For example in one typical experiment the blood plasma protein was 6.3 Gm per hundred cubic centimeters and the fluid protein 5.7 Gm. In twenty-seven experiments the amount of this peritoneal fluid averaged 2.5 per cent of the body weight, which corresponds to 250 cc in a 10 Kg dog and in turn to 33 per cent of the blood volume and to approximately 60 per cent of the plasma volume. It was assumed that this outflow of plasma-like fluid accounts for a large part of the blood concentration with increased hemoglobin percentage and hematocrit reading for the decreased bleeding volume and for the marked fall in blood pressure. Blalock,⁷ Parsons and Phemister⁸ and others have shown that a somewhat similar loss in burns, trauma to an extremity, intestinal manipulation, hemorrhage, plasma pheresis and other conditions is sufficient to cause death. The same evidence indicates its importance in the production of secondary shock and the resultant death in bile peritonitis.

Since the aforementioned work indicated that secondary shock might be an important lethal factor in bile peritonitis, it was thought that it might likewise be significant in death due to intraperitoneal insertion of tissues (so-called tissue autolysis *in vivo*). The clinical importance of tissue autolysis is especially to be considered when ligating large bits of tissue in producing hemostasis in surgical operations.

LITERATURE ON LIVER AUTOLYSIS⁹

Mann⁹ noted that, if in the performance of a hepatectomy a small amount of liver was left in the abdomen, the animal was more apt to die than when the liver was completely removed. Mason and his associates¹⁰ extended the work of Mann. These authors in their first experiments on dogs replaced an excised portion of liver in the same animal and showed that there was a marked decrease in plasma volume. At postmortem examination they found that the peritoneal

cavity usually contained from 100 to 300 cc of brown fibrin-flecked fluid. This fluid contained a considerable amount of nonprotein nitrogen, but they did not report any analysis for total protein content. When injected intravenously into other animals the abdominal fluid was much less toxic than saline extracts of autolyzed liver.¹¹ These authors¹² also reported that, when the spleen was separated from its blood supply and left free in the peritoneal cavity, death occurred in 50 per cent of the animals studied and was accompanied by an outpouring of fluid into the peritoneal cavity similar to that found in liver autolysis. In general, spleen acted similarly to liver but did not produce death so easily or so soon.

Wangensteen and Waldron¹³ also performed experiments on autolysis of intestine, liver, spleen, muscle and other tissues. After intraperitoneal insertion of these tissues the authors found 300 or 400 cc of sero-sanguineous fluid in the peritoneal cavity. The peritoneal surfaces were reddened and gas was often found. No mention of anaerobic cultures was made. They

substances when permitted to grow in dead liver, and that it is the absorption of these poisons from the peritoneal cavity that causes death in *in vivo* liver autolysis. They furthermore reported that fetal liver, proved sterile by culture, does not produce any toxic effect.

Andrews and his associates¹⁶ performed experiments that differed from those of Dragstedt in one important respect. Whereas the latter had found that sterile autoclaved liver was nontoxic, Andrews reported that if such sterile liver was ground into fine bits it produced an autolytic peritonitis accompanied by gas forming organisms similar to that produced by fresh liver. Andrews also reported that muscle or bile salts would produce a similar fatal peritonitis.

Later work of Mason¹⁷ again called attention to the extensive loss of fluid in these experiments, especially into the peritoneal cavity. The large amount of peritoneal exudate had also been noted by Dragstedt and by Andrews. Mason and his collaborators believed that irritative substances liberated from the autolyzing liver

found that spleen was less lethal than liver, and the animals suffering from the action of spleen could sometimes be kept alive by subcutaneous administration of saline solution.

Dragstedt and his associates¹⁴ began work on autolysis of intestinal loops separated from their blood supply and reported that the *in vivo* autolysis of short isolated sections of intestine that had been sterilized by prolonged drainage into the peritoneal cavity did not produce any serious effect in dogs. When such segments were infected, however, death followed shortly after the occlusion of their blood supply. Ellis and Dragstedt¹⁵ later performed experiments on liver autolysis. They reported that the uncontaminated liver of a normal healthy adult dog regularly contains a gram-positive anaerobic bacillus and concluded that this organism probably forms exceedingly poisonous

cause a chemical peritonitis with increased permeability of the peritoneal surface. This results in passage of both bacteria and fluid into the peritoneal cavity. They further believed that the fluid loss is sufficient to cause circulatory disturbances but that the failure of fluid administration to prolong life was due to the enormous increase in permeability of the abdominal viscera.

Trusler, Reeves and Martin¹⁸ in a series of papers made a special study of the anaerobic bacteria found in experimental liver autolysis and bile peritonitis. These organisms did not produce exotoxins and were similar to those recovered from normal dog liver and muscle. The authors did not classify them as *Clostridium Welchii*. They found that sterile autoclaved liver or bile salts did not cause invasion of the peritoneal cavity by anaerobic organisms if contamination by touching the muscles of the abdominal wall during the process of insertion was avoided. These authors noted that the various incubated preparations of liver and sterile bile salts cause an intense irritation of the peritoneal sur-

all but one instance. In two of the animals definite gas was present in the intraperitoneal tissues, and in all instances gram-positive anaerobic bacilli were found on culture. This indicates that both secondary shock and the effects of infection are to be considered as responsible for death in these animals. If, however, as Trusler, Reeves and Martin¹⁸ postulate, the dog's anaerobic organisms produce no exotoxins, it would seem unlikely that the small amount of infection produced by these organisms would cause death while much more extensive infection by definite pathogenic anaerobes in human beings would not do so as quickly. The absorption of toxic products from the decomposed liver is to be considered, therefore, as an additional lethal factor.

EXPERIMENT 3—Peritonitis and death produced by the intraperitoneal insertion of fresh muscle. Fresh muscle obtained sterilely from a dog's thigh was chopped up and ground and then 100 Gm implanted in the peritoneal cavity of each of two animals by the technique of experiment 2-a. Death occurred in nine and twelve hours. There was very little hemoconcentration.

Andrews¹⁶ Although gram-positive anaerobic bacilli were found in both animals that died, no gross signs of infection were present.

EXPERIMENT 5—Peritonitis and death produced by the intraperitoneal insertion of incubated muscle. A quantity of dog muscle was incubated at 37 C with *Bacillus sporogenes* and another quantity with *Clostridium Welchii* for thirty-six hours. They were then autoclaved for twenty minutes at 20 pounds pressure. The resultant semiliquid soupy mash was in each case sterile on culture and 150 Gm of each was placed intraperitoneally in two dogs. The muscle that was incubated with *Bacillus sporogenes* produced marked hemoconcentration and death in seven hours, but only 200 cc. of spontaneously clotting peritoneal fluid (which included the remains of the semiliquid muscle implant). This animal was the only one in the entire series definitely known to have died in convulsions. Necropsy revealed moderate hemorrhages in the peritoneal surfaces, mesenteric glands, duodenum, jejunum and part of the ileum. There were no hemorrhages in the adrenal glands and no edema of the dependent portions of the back. There was slight edema of the lungs. The muscle that had been incubated with *Clostridium Welchii* produced marked hemoconcentration, death in eighteen hours and only 110 cc of nonclotting bloody peri-

Chart 3—Blood pressure changes in peritonitis due to liver autolysis.

tion and very little fluid found in the peritoneal cavity at necropsy. The spleen was sterilely removed from two dogs and cut and ground. This mash was then implanted into the peritoneal cavity of one of the two splenectomized dogs. This animal (dog 326) died after seven hours with rather marked hemoconcentration (hemoglobin rise from 118 to 158, hematocrit rise from 50 to 69), but with little peritoneal exudate.

This experiment indicates that death may occur in fresh tissue autolysis in the absence of either local fluid loss or of generalized blood concentration. Moon and Kennedy¹⁹ reported concentration of the blood following intraperitoneal insertion of muscle fragments with an increase of almost 3 million in the red count in one instance.

EXPERIMENT 4—Peritonitis produced by the intraperitoneal insertion of autoclaved liver. One hundred grams of autoclaved liver mash was implanted intraperitoneally with similar technique in each of three dogs. Autoclaving was done for twenty minutes at 20 pounds pressure and afterward aerobic and anaerobic cultures showed the liver to be sterile. Hemoconcentration was much slighter than when fresh liver was used, death occurred later (average of thirty hours in two instances, recovery in the third) and there was relatively little peritoneal exudate.

Some other cause of death than local fluid loss was active in these animals. At necropsy there was no gas and the liver was not blown up or markedly discolored as in the typical autolytic peritonitis described by

peritoneal fluid. Necropsy revealed marked hemorrhages in all the peritoneal surfaces, duodenum, adrenals, mesenteric glands and lungs. There was marked edema of the dependent portions of the back.

While the marked hemoconcentration in these two animals indicated a possible plasma loss from the blood stream, there was no proportionate loss into the peritoneal cavity. The only indications of loss elsewhere were the localized hemorrhagic changes and the dependent edema of the second dog. However, it seems quite probable that fluid loss with secondary shock was not the chief factor in the death of these animals. Exotoxins produced by the action of the anaerobic organisms may have been a factor, as stock cultures of known toxin-producing strains were used. This would not necessarily apply to the autolysis or incubation of tissue in the other experiments, for in them the gram-positive anaerobic bacilli were from dog tissues, which according to Trusler and his associates do not produce exotoxins.

EXPERIMENT 6—Subcutaneous implantation of liver with resultant death. Autoclaved liver mash was placed subcutaneously in the axilla and groin of one side of each of three dogs, two of the specimens having been previously incubated for at least six hours. Hemoconcentration was appreciable in only one of the three animals and death occurred after twenty, twenty-three and seven hours respectively. The dorsal and ventral midlines of the animals having been previously marked, bisection was done and the difference in weight of the two sides (corrected for the amount of liver inserted) averaged 23 per cent of the

¹⁹ Moon, V. H. and Kennedy, P. J. Pathology of Shock, Arch Path. 14: 360-371 (Sept.) 1932. Changes in Blood Concentration Incident to Shock. J. Lab. & Clin. Med. 18: 295 (Dec.) 1933.

body weight. However, the dog which died the most rapidly had the smallest amount of local fluid loss and dissection revealed no edema. Necropsy of these animals showed hemorrhagic changes in the adrenals, mesenteric glands and to a less extent in the intestine.

While fluid loss may thus be a factor in death from subcutaneous implantation of liver, it does not seem to occur invariably. This is in marked contradistinction to the effects of subcutaneous bile salt injection, in which death of the experimental animals was almost invariably associated with a marked local fluid loss.

COMMENT

While extensive loss of plasma-like fluid into the peritoneal cavity seems to be a lethal factor of importance in experimental bile peritonitis, the evidence that such is the case in death due to experimental implantation of liver in the peritoneal cavity is not only inconclusive but instead seems to point toward other causes. In experimental bile peritonitis, gram-positive anaerobic bacilli were found in only a small proportion of cases and then usually as either late or postmortem invaders. In peritonitis following liver implantation, on the other hand, such organisms were found in all instances. It is quite possible that these organisms act chiefly in breaking up the liver or other tissue into toxic substances. Such action may be chemical in producing toxic proteose-like substances or may be merely mechanical with disruption of the tissue into finer particles, as the result of the explosive action of the gas. When broken up into such particles the action may be partly that of a local irritant producing some local fluid loss and partly that of a general toxic agent. In addition, some of these substances may give rise to a generalized increased permeability of the vascular system with a generalized loss of circulating blood fluid. It is only by considering these factors working simultaneously that a complete picture of the mechanism of death due to liver implantation can be drawn. At the present time it seems unwise to say that one of these factors is the only element of importance or even the chief instrument of death. These causes may work coordinately in bile peritonitis as well, but in the latter the local irritating effect of the bile produces such a regional outpouring of fluid that the factor of secondary shock outweighs and overshadows the rest. In liver autolysis, on the other hand, the less irritating broken-down liver juices may produce a general toxic action out of proportion to the local fluid loss before the latter has reached dangerous proportions.

While certain of these experiments, especially those on bile peritonitis, indicate that there is such a thing as irritative peritonitis in which local fluid loss may be a lethal factor of importance, the exact cause of death in all instances is not clear. The peritoneal cavity in liver autolysis experiments contains a vicious mixture of irritant, foreign body, bacteria and injured tissues of the host. To say that there is one cause of death in such a case is difficult. At least it is brought to attention that fragments of foreign or devitalized parenchymatous tissues should not be left in patients.

SUMMARY AND CONCLUSIONS

1. At least five possible lethal factors in experimental peritonitis due to bile or to implanted liver may be active, including (a) local irritant action of the foreign substance producing local plasma loss and secondary shock, (b) local damage to body tissues with absorption of toxic products thereby produced, (c)

absorption of toxic products from the foreign substance itself, (d) absorption of exotoxins produced by anaerobic organisms or of toxic products produced by the action of these organisms on the foreign substance present or the body tissues themselves, and (e) action of absorbed products on general vascular permeability furthering secondary shock.

2. The first of these factors, i. e., producing local plasma loss and secondary shock, seems to be of relatively greater importance in bile peritonitis than in peritonitis due to implanted liver. In the treatment of bile peritonitis attention should be directed against the possible presence of secondary shock.

950 East Fifty-Ninth Street

ABSTRACT OF DISCUSSION

DR. THOMAS G. ORR, Kansas City, Mo. In clinical medicine the important question is whether or not bile in the free peritoneal cavity will cause peritonitis. Some writers have expressed the opinion that bile does little damage to the peritoneum unless infected. Both experimental and clinical observations indicate that the effect of sterile bile within the peritoneal cavity varies directly with the quantity of bile. This was definitely true in a series of experiments on dogs which Dr. A. M. Ziegler and I did a few years ago. After we had incised the gallbladder and drained its contents into the peritoneal cavity several of our animals recovered without any noticeable clinical symptoms. Autopsy revealed that the gallbladder fundus had healed without evidence of any general peritonitis and with only a few adhesions about the immediate vicinity of the gallbladder. This is undoubtedly what happens in patients. During and following operation on the gall tract, especially the common duct, there is frequently soiling of the regional peritoneum without any serious clinical results. On the other hand, in traumatic rupture of the gallbladder or ducts a general bile ascites may be caused which will result in death if not relieved by operation. In such cases the peritoneum shows an inflammatory reaction but no suppuration. Spontaneous rupture of the gallbladder is usually associated with infection and has a very high mortality rate. The experiments reported here today prove conclusively that uninfected bile in the peritoneal cavity of the dog in sufficient quantity will produce death in a very few hours. The rapid lowering of blood pressure, the blood concentration and the marked effusion of fluid into the peritoneal cavity with a high protein content indicate that secondary shock may be a lethal factor. Since human bile is apparently less toxic than dog bile, I am very doubtful whether the shock syndrome plays a very important role as a mortality factor in patients.

DR. EDWARD C. MASON, Oklahoma City. In working on this problem my associates and I have considered it from three different angles. Our first impression was that a toxic substance was liberated from the sectioned liver and we still believe that such is the case. More recently we have published observations which demonstrate that the peripheral portion of the rabbit's liver would remain sterile within the abdominal cavity and undergo aseptic autolysis. Such autolysis was accomplished by pathologic changes especially in the liver and kidneys. The second possible cause of death was introduced by Drs. Ellis and Dragstedt, who called attention to the presence of a Welch-like organism. This organism has been found at autopsy in all our animals dying following section of liver tissue. At present we feel that the function of the organism is only that of intensifying the liberation of toxic substances from the sectioned liver tissue. The organism may be injected intraperitoneally without producing harmful effects, also it may be placed in the abdomen infiltrated in fetal liver without causing death. Recently we have injected the organism intravenously, together with its substrate, without causing harmful effects. The last factor, that of dehydration was considered in our first paper on autolysis and again recently we have tried to keep the animals alive, crowding fluids by mouth stomach tube intravenous salt solution dextrose solution and gum in salt solution. We found that such crowding of fluids caused an

increase in the amount of fluid in the peritoneal cavity following death but failed to prolong the life of the animals. Our results were therefore similar to those subsequently repeated by Blalock, who observed that intravenous administration of fluids in clinical peritonitis was also accomplished by a marked increase in intraperitoneal fluid. We concluded in 1935 that three factors were active in causing the death of our animals and that the chain of events included (a) the toxic material liberated from the sectioned liver, (b) the bacterial action which intensifies the liberation of this toxin, and (c) increased permeability resulting from chemical irritation by the material.

Dr. M. PINSON NEAL, Columbia Mo. The authors did not mention observations on the pancreas. I should like to ask whether interpretations were made on lesions demonstrable grossly or microscopically in that organ. Rewbridge in 1931 recorded an experimental study of bile peritonitis produced by the artificial escape of bile from the pancreatic ducts. In cultures from the peritoneal exudates he found gas-producing organisms. To get away from the bacterial agents, he used sterile bile salt injections and produced the same type of so-called bile peritonitis. Rewbridge in this work found a rather high percentage of his animals showing fat necrosis and concluded that the fat necrosis found in the pancreas, omentum and mesentery was due to some change in the pancreas or pancreatic ducts that permitted the escape of pancreatic juice into the peritoneal cavity. With a co-worker, I have been particularly interested in fat necrosis for a number of years. We have produced experimental fat necrosis by pure lipase obtained from fresh hog's pancreas, liver, and commercial pancreatins. We have also produced it by lipase extracts from vegetable sources, which eliminated trypsin. It would be very valuable if Dr. Harkins and his co-workers have some observation on pancreatic lesions or of fat necrosis to add to their recorded observations.

Dr. H. M. TRUSLER, Indianapolis. I have been interested in the subject for several years and have recognized the fact that these animals die from shock. The results of unpublished blood chemical studies agree with those of the authors and are somewhat more elaborate. There are some interesting things about fresh liver that have not been mentioned. If an adult dog liver is ground in a food chopper with equal parts of physiologic solution of sodium chloride and the gross connective tissues are removed, the emulsion of liver cells that remains may then be injected through an 18 or 20 gage needle. Large amounts of this preparation may be injected into a dog and it will not kill him, even though a rich bacterial flora is present. In other words the fresh liver cell suspension, even in 100 Gm quantities, may be injected intraperitoneally into a normal dog without causing death. The connective tissue from the same liver when injected in a similar fashion is rapidly fatal to the dog. The animal dies in a state of shock and the peritoneal fluid shows a rich growth of the liver organisms. If, however, this fresh liver is autoclaved and finely ground it can then be introduced into the peritoneal cavity, even after deliberate inoculation with the liver organism, and most of the animals will survive. Those which do die may live for a period of ten days. The picture is entirely different from the shock syndrome that has been described by the authors. Certainly autoclaving the liver does something to it so that it is no longer very toxic. The change does not seem to be merely a matter of sterilization. If this liver tissue is incubated for twenty-four hours or more and is then autoclaved, it is extremely toxic and kills the animal in a state of shock even though the peritoneum in this case remains sterile. There are some interesting things about this shock picture. It is more severe and differs considerably from traumatic shock or shock due to hemorrhage. For one thing, there is a tremendous initial rise in blood sugar after this injection and then the blood sugar falls sharply to a very low level, so that the animal at death may have a blood sugar of 50 mg.

Dr. ANTON J. CARLSON, Chicago. I am sorry Dr. Horrall is not here to discuss this paper. He did his work in my laboratory a number of years ago. I wish to congratulate Dr. Harkins and his co-authors on well conceived experiments. So far as I know, the emphasis on the loss of fluid from the blood vessels in bile shock is new. But there are other factors. We know that the bile does not need to be put in the peritoneum

to kill, intravenous injection of bile kills. I am ready to accept the conclusion that where this large amount of fluid is lost it is a contributory factor in death. It is astonishing how much blood a normal dog can lose without dying, without going into shock. Of course, if there are poisons in the system such as anesthetics, bile or other irritants over the whole peritoneum, smaller quantities of blood loss will probably cause death by shock.

Dr. NORMAN E. FREEMAN, Boston. Much has been said concerning the loss of plasma into traumatized regions as the mechanism for the reduction of blood volume in surgical shock. The amount of fluid in the peritoneal cavity in certain of the authors' experiments furnishes an example of such a mechanism. I fully believe that this loss of plasma is of real significance. In addition, the possibility of absorption of toxic substances has been discussed. Ether has also been mentioned as one of the factors that may produce shock. There is an additional factor which I believe may be of some importance in the production of shock in these experiments which has not been brought up. That factor is the afferent stimulation from the chemical trauma to the peritoneal cavity. It is recognized that vasoconstriction is produced by afferent stimulation. Vasoconstriction, if prolonged, may lead to blood concentration and a reduction of blood volume. Possibly the traumatic action of the substances introduced into the peritoneal cavity might have produced sufficient reflex vasoconstriction to be in part responsible for some of the interesting results which the authors have reported.

Dr. HENRY N. HARKINS, Chicago. I mentioned the difference between human and experimental bile peritonitis, the reason for which is partly the marked difference in concentration between gallbladder bile and duct bile. If the bile acts as an irritant, the more concentrated bile undoubtedly is much more irritant. We did all our experiments on bile peritonitis with gallbladder bile taken from a number of other dogs and inserted into one dog, using more than we could get from one single dog. In human beings, even if a fairly large gallbladder ruptures, 50 or 60 cc. very little bladder bile is lost. If after operation there is a leakage from the common duct, such leakage is of the less irritating bile. In our experiments we required at least 2 cc. of gallbladder bile per kilogram to produce death. In an ordinary sized man this corresponds to about 150 cc. Very seldom does that much concentrated bile result from rupture of a gallbladder. Referring to Dr. Mason's statement concerning posture we noticed no special position assumed by the animals at death. Our work differed from that of some previous workers in that instead of leaving the animals alone after injection of bile and finding them dead the next morning, we sat up and watched them as they died. We did not notice any peculiar position at the time of death. Of all the series of dogs, only one dog died in convulsions. Concerning the anaerobic organisms present in these conditions, it is of interest that, while they were found by us at death in every case in which liver was implanted intraperitoneally, they were not found regularly in bile peritonitis. These cultures were taken immediately at death rather than at some indeterminate time later. I wish to point out that both Dr. Trusler and Dr. Mason mentioned some time ago that these conditions may be associated with shock and that this idea is not original with us. The bacteria that Dr. Trusler and his associates isolated from the peritoneal cavity were said by them not to produce exotoxins. In certain animals in which there was not sufficient peritoneal fluid to account for death, very extensive edema of the dependent portions of the body was present and it is possible that the fluid might have gone to these other regions. Dr. Carlson has mentioned that large amounts of blood can be lost from the dog without production of death. In animal experiments, Blalock and others have shown that blood plasma can be lost in much smaller amounts than whole blood, the ratio of the two being about one of plasma to two of whole blood. We have noticed that as the time of death approached even in animals in which the blood pressure had not yet fallen markedly there was a vasoconstriction of the peripheral vessels as denoted by the fact that, when the ears were cut for blood counts, blood was very difficult to obtain. In several instances we had to cut even the femoral artery to obtain sufficient blood for blood counts.

THE CORBUS-FERRY GONOCOCCUS BOUILLON FILTRATE

A CLINICAL STUDY

ROGERS DEAKIN, M.D.

Chief of the Genito-Urinary Clinic Washington University
Outpatient Department
ST. LOUIS

The Genito-Urinary Section of the Washington University Outpatient Department has for some time been engaged in a study of the various medicaments and procedures proposed for the most intelligent treatment of gonorrhea and its complications. We have felt that carefully controlled and conscientiously studied clinical research in these cases was quite compatible with and could be carried out without sacrificing unduly the primary function of the clinic, namely, to cure the disease in the simplest, speediest and most economical way possible, as well as to carry out as much of an educational program as we could under the circumstances.

Like most such clinics connected with a teaching institution, we have had to depend on physicians who volunteered their services and time, we have had to combat poverty, ignorance, indifference and general viciousness on the part of the patient, and the attempt

TABLE 1—Acute Gonorrhea

| | Filtrate | No Filtrate |
|------------------------------|--|--|
| Negative complement fixation | 8 cases O K 4 recurrences 1 epididymitis 1 arthritis 1 prostatitis | 5 cases O K 2 recurrences 1 epididymitis 1 acute posterior urethritis 1 persistent infection |
| Positive complement fixation | 6 cases O K 8 recurrences 2 epididymitis 2 prostatitis | 3 cases O K |

to get a sufficient number of carefully observed controlled cases is, and I suppose always will be, the occasion for much discouragement. The tremendous amount of work that must be discarded because of the failure of the patients to return until their case is closed to the complete satisfaction of the investigator has caused many a doctor to give up the problem, which he started in earnest good faith and allowed to drop in disgust because of the apparent complete indifference of the average clinic patient.

We do believe, however, that such a clinic is the place to test out every claim, be it for a vaccine, a new chemical or what not, which has any semblance of decency in either its origin or its rationale, and because of this we have consistently encouraged at least a preliminary trial of various substances advocated in the therapeutics of gonorrhea.

We have been studying the Corbus-Ferry gonococcus bouillon filtrate for a year. That we have kept it up that long is in itself an indication that we felt it had clinical merit. As a matter of fact, we were furnished a considerable amount of the original experimental product four or five years ago, and while no report was made, since we saw no startling benefit from its use at that time, even then there were indications that it or a similar product might eventually lead to something. Accordingly, when the opportunity was again offered to use the newer filtrate we were happy to undertake a series of cases such as is reviewed here.

Dr. Ralph Muckenfuss of the laboratory encouraged us to begin the routine use of the complement fix-

ation test for gonorrhea at the start for two reasons: first, that we might determine, at least for our own information, its general value in gonorrheal work, and second, since we were using an immunologic or antigenic agent as a therapeutic measure, it would not be inappropriate to correlate a study of the antigenic response of the blood in both filtrate and nonfiltrate cases.¹ To date we have almost a thousand blood reports on gonorrheal and nongonorrheal cases, which I intend at some later date to summarize.

During the past year we have started 112 men with acute or chronic gonorrhea² on the filtrate. Fifty-two

TABLE 2—Chronic Gonorrhea

| | Filtrate | No Filtrate |
|------------------------------|---|-------------------------------|
| Negative complement fixation | 9 cases O K 2 prostatitis | 8 cases O K 2 recurrences |
| Positive complement fixation | 1 case O K 5 recurrences 2 epididymitis | 6 cases O K 1 epididymitis |

of them may properly be included in the statistics presented together with thirty control cases. The other sixty filtrate cases and a similar percentage of controls have had to be discarded for one reason or another, mainly because this type of person in a clinic usually has no interest in his troubles past the stage when it is no longer painful to urinate.

The local treatment in both groups consisted of urethral injections of 0.5 per cent solution of strong protein silver twice daily and 10 minims (0.65 cc) of oil of santal by mouth three times a day. The filtrate group received in addition weekly intradermal injections of the filtrate starting with 0.5 or 0.1 cc and increasing 0.1 cc each time until 0.7 cc was reached. Variations of this program were made when indicated according to the manufacturer's directions. Even though I did not give each treatment personally, I assumed complete responsibility for the therapy instituted, so that the two seniors who were doing most of the actual work would be carrying out in the main a routine type of local treatment in both the filtrate

Chart 1—Percentage of positive smears in acute and chronic gonorrhea. Solid line Corbus-Ferry filtrate; broken line no Corbus-Ferry filtrate.

and control groups. The personal equation would therefore be that much more limited and certainly subject to the same errors and limitations in each group.

1. The technic for the complement fixation test follows that described by R. F. Parker (J. Infect. Dis. 55: 88 [July-Aug. 1934]) except for fixation at 37°C for one hour instead of five hours at 5°C.

2. Men with no history of a previous gonorrhea who presented themselves for treatment within six weeks from the onset of their discharge were considered to have acute gonorrhea. Those who had had their disease longer or who gave a history of repeated infections were considered to have chronic gonorrhea.

In the first curve (chart 1), designed to show the behavior of the acute and chronic cases together, with and without the filtrate, the percentage of positive smears obtained on successive weeks and months from each group has been charted. I do not wish to leave the impression that we were able to obtain such smears on every successive week or month in every patient. On the contrary, there are fairly numerous breaks. We have repeatedly recorded positives, for instance, in weeks following a definite positive finding until a definite negative or positive was obtained. In the same manner, negatives have been inserted in blank weeks where negatives preceded and succeeded the interpolated record. I do wish it to be plain, however, that we tried hard to make weekly or monthly smears in each case, so that the interpolations have been relatively few.

I fully appreciate that this type of curve represents but one phase of the case progress, but it is adaptable to representation in chart form and indicative of the course of the disease. A comparison of these curves with clinical progress can be made by referring to the initial differentiation between filtrate and nonfiltrate case in table 3.

Chart 2—Percentage of positive smears in acute gonorrhea. Solid line, Corbus-Ferry filtrate; broken line, no Corbus-Ferry filtrate.

The second curve (chart 2) contrasts the behavior of the acute gonorrheas only with and without the filtrate in the same manner.

The third curve (chart 3) is a similar comparison of the chronic gonorrheas.

The late rise in both charts 2 and 3 may be explained by an occasional positive smear from recurrence, or possible reinfection, at a time when most of the patients had been dismissed. One or two such positives in a relatively small group of smears creates a relative disproportion in the curve. For instance, in chart 3, six out of eighteen men given the filtrate were still under observation in the eighth month. Of these, two had positive smears and four were negative.

At the same time, if one again refers to table 3, in which a percentage result according to clinical progress is recorded, it will be seen that the somewhat poorer behavior of the filtrate cases in both the acute and chronic gonorrheas is definitely reflected in these curves made from the tabulation of smears.

Tables 1 and 2 show in brief the clinical results obtained in the acute and chronic groups with and without the filtrate, further subdivided according to the behavior of the complement fixation test. An uneventful course from onset to cure is considered "O. K." A complication of any sort made the case "unsatisfac-

tory," even though the clinical course, so far as time element or end results were concerned, proved satisfactory eventually.

The degree of reaction of the complement fixation test is not differentiated in tables 1 and 2. If the individual at no time while he was under observation showed any degree of fixation, he was placed in the

Chart 3—Percentage of positive smears in chronic gonorrhea. Solid line, Corbus-Ferry filtrate; broken line, no Corbus-Ferry filtrate.

negative blood group. On the other hand, any report of from one plus to four plus from the laboratory at any time during his disease caused us to include him in the positive blood group. Needless to say, many individuals never showed anything more than a weak reaction, some stayed strongly positive during their entire observation, and most of those who developed a four plus reaction showed a definite improvement or complete change to negative as treatment and observation continued.

The analysis of the cases (table 3) proved most interesting. If the cases (eighty-two in all) were divided simply into two groups, filtrate or no filtrate, there is an appreciable difference in their clinical performance as evidenced by the percentage figures 46 and 73. Continue this analysis, but separate the acute from the chronic cases, again with and without the filtrate, and the percentage figures obtained give the

Chart 4—Percentage of positive smears in chronic gonorrhea. Solid line, positive blood group with filtrate; broken line, positive blood group with no filtrate; negative blood group with filtrate, and negative blood group with no filtrate.

impression that it is the acute gonorrheal group placed on the filtrate at the onset of their disease which suffers by comparison with those acute cases in which the filtrate was not administered and the filtrate and nonfiltrate chronic gonorrheas. Even here in the chronic gonorrheas with filtrate the percentage of satisfactory

clinical results (52 per cent) is lower than the general average (nonfiltrate, 73 per cent) or the 82 per cent in the chronic group without filtrate

However, if the group is still further subdivided, so that the acute and chronic groups are considered according to whether or not their bloods were positive or remained consistently negative, again with or without

TABLE 3—Percentages of Satisfactory Clinical Results

| Type of Case | Complement Fixation | No of Cases | Therapy | No of Cases | Percentage O. K. |
|-------------------|---------------------|-------------|-------------|-------------|------------------|
| Acute and chronic | | 82 | Filtrate | 52 | 46 |
| | | | No filtrate | 30 | 73 |
| Acute | | 46 | Filtrate | 33 | 42 |
| | | | No filtrate | 13 | 61 |
| Chronic | | 38 | Filtrate | 19 | 52 |
| | | | No filtrate | 17 | 82 |
| Acute | Positive | 21 | Filtrate | 18 | 83 |
| | | | No filtrate | 3 | 100 |
| | Negative | 25 | Filtrate | 15 | 53 |
| | | | No filtrate | 10 | 50 |
| Chronic | Positive | 15 | Filtrate | 8 | 13 |
| | | | No filtrate | 7 | 88 |
| | Negative | 21 | Filtrate | 11 | 82 |
| | | | No filtrate | 10 | 80 |

the filtrate, it will be noted that in the acute group the results generally were rather unsatisfactory except for the nonfiltrate group with positive blood. The number of individuals that could be included here, however, is too small to justify much consideration.

The most startling discrepancies appear in the chronic group, in which a combination of positive blood and the filtrate therapy gave a very low percentage of good results (13) and in the remaining three groups, one with positive blood and no filtrate, a second with negative blood and filtrate, and the third with negative blood and no filtrate gave us a very high percentage (86, 82 and 80) of clinically satisfactory results.

To see whether this interesting fact with regard to the chronic gonorrheas was substantiated in any other way, I again resorted to a plotted curve in which the cases included in the positive blood filtrate group (13 per cent clinically satisfactory) are plotted against the other three chronic groups, and chart 4 presents what I consider irrefutable evidence of the accuracy of our observations. In this chart the tendency of the patients to retain their positive smears and the erratic nature of the curve due to relapses and complications in the chronic group in which positive bloods had developed and the filtrate had been given is so definite as compared with the smooth course indicated in the remaining chronic cases as to make me believe that the use of the filtrate in a chronic case with positive blood is quite contraindicated.

COMMENT

In the beginning I pointed out that we had as a routine procedure and almost without exception continued the use of the filtrate up to 0.7 cc. It is quite possible that, as Dr. Corbus has pointed out, this represented an overdosage for some of the individuals under study. We were, however, on the look out constantly for skin reactions which would indicate that we were approaching or had reached the limit of injection and did not knowingly exceed this amount at any time. Moreover, I am quite sure that we did not in any case see the acute local exacerbation that has been described by Dr. Corbus and others.

It is not within the province of this paper to undertake a discussion of the immunologic or serologic properties of the Corbus-Ferry gonococcus bouillon filtrate. To me, clinically, it has specific properties that may

produce a good or bad result, depending on the type of case or perhaps the manner in which it is used therapeutically. Furthermore, I am unable to correlate our results with the reported good results obtained in gonorrheal arthritis, in which the complement fixation is nearly always positive. We have not seen enough arthritis of this sort to be able to report any results. It seems to me, however, that a possible explanation for some of our results may lie in this possibility, i. e., that the filtrate serves to break down the natural walling off and sterilizing process which the body contrives against further invasion by the gonococcus much as tuberculin does in certain types of tuberculosis.

SUMMARY

A series of both acute and chronic cases of gonorrhea from an outpatient clinic, in which the Corbus-Ferry gonococcus bouillon filtrate was used in a routine manner were compared with a control group. In both instances the same local treatment and general hygienic measures were instituted. Complement fixation tests were made repeatedly in all cases.

The results would indicate that acute gonorrheas do not do as well with the filtrate as without, that the poorest results with the filtrate are obtained in chronic gonorrhea with a positive gonococcus complement fixation, and that the best results are obtained in chronic gonorrhea with a consistently negative complement fixation test.

THE PRESERVATION AND CONCENTRATION OF HUMAN SERUMS FOR CLINICAL USE

STUART MUDD, MD
EARL W. FLOSDORF, PHD
HARRY EAGLE, MD
JOSEPH STOKES, JR, MD
AND
AIMS C. MCGUINNESS, MD
PHILADELPHIA

During convalescence from many infectious diseases the blood contains antibodies that are capable of conferring passive immunity. Transfer of convalescent human blood, plasma or serum to a susceptible recipient before or during exposure or in the incubation period of a number of diseases may give either complete protection or attenuation. In a smaller number of infections, therapeutic benefit may also be anticipated from convalescent human serum. The difficulty of obtaining such serum in sufficient amounts, however, and its cost must necessarily impose limitations on its use.

Healthy adults afford a second and less limited source of human serum the value of which lies chiefly in the prevention and less frequently the treatment of the infectious diseases of childhood. The passive immunity that is transmitted transplacentally from the mother to the new-born infant is lost during the first year of life. Acquisition of active immunity occurs slowly and reaches its maximum only in early adult life.¹ During the years of childhood humoral immunity

From the Departments of Bacteriology and Pediatrics, University of Pennsylvania School of Medicine and the Children's Hospital of Philadelphia.

1. For detailed discussion of this process and of the relative roles in it of infection and of physiologic maturation refer to: Topley W. W. C. *An Outline of Immunity*. Baltimore: Williams & Co. 1933 or Baumgartner Leopold. *The Relationship of Age to Immunological Reactions*. Yale J. Biol. & Med. 40:5 (March) 1935.

is in general low and may be augmented at critical times of exposure or definite infection by the serum of properly chosen healthy adults

Donors artificially immunized against a given infectious agent are a third possible source of human serum. Thus far utilization of this source has been chiefly in the relatively small number of cases treated by specific immunotransfusion. A number of experiments with specifically immunized donors are in progress now, however, and this method may well find much wider application in the future.

Human serums afford a means of prophylaxis against certain diseases for which animal serums are not obtainable, for instance, measles, chickenpox and mumps. With reference to other diseases the choice of human versus animal serum is determined largely by practical considerations of availability and potency. In the treatment of such severe and acute diseases as diphtheria, meningococcal meningitis and type I lobar pneumonia or in the prophylaxis of tetanus, horse antisera of high potency are clearly the agents of choice.

In the management of streptococcal infections, on the other hand, there is definite competition between human and horse serums, and the present trend is toward the use of human serum. The considerations involved are complex. Hemolytic streptococci are both toxigenic and invasive, and the ideal therapeutic agent should contain both antitoxic and antibacterial antibodies. The problem of obtaining the required antibacterial properties is rendered exceedingly difficult by the fact that there are at least twenty-seven known serologic types of streptococci among the human pathogens² and that a given disease such as scarlet fever may be caused by any one of a considerable number of these types. Streptococcus horse serums of adequate polyvalence in antibacterial properties have yet to be prepared. On the other hand, there is much evidence of the presence of specific antistreptococcus antibodies in the serums of human beings convalescent from streptococcal disease.³ In our judgment, therefore, the best expedient at the moment available for obtaining antibacterial serums of adequate polyvalence against hemolytic streptococci is the use of large pools of serum from scarlet fever convalescents or from healthy Dick-negative normal adult donors. Such theoretical considerations find some practical substantiation from the favorable results with pooled human serums reported by Weaver,⁴ Meader,⁵ Hoyne, Levinson and Thalhimer,⁶ McGuinness, Stokes and Mudd,⁷ and others in the prevention and treatment of scarlet fever and its complications, and in the treatment of other hemolytic

streptococcus infections.⁸ With regard to antitoxic properties, properly prepared horse serums are undoubtedly of far higher potency.⁹ Yet this advantage is outweighed in the minds of many clinicians by the disadvantages of serum sickness and the possibility of anaphylactic accidents with the use of horse serum.

Methods for the preservation of serum with a minimum of deterioration have been evolving for nearly half a century. Desiccation¹⁰ was an early method of definite value. More recently work¹¹ has indicated desiccation in vacuo from the frozen state to be the best method at present known. Procedure and apparatus for desiccation in vacuo from the frozen state have been fully described in a recent publication.¹² Briefly, the serum or other biologic material to be preserved is distributed with sterile precautions into glass containers. These are immersed in a bath of Dry-Ice in a commercial solvent (Methyl Cellosolve) at a temperature of approximately -75°C . The containers of the frozen serum are attached to a manifold which leads through a condenser to a vacuum pump. The condenser is kept at -75°C with a bath of Dry-Ice in the same solvent. The whole system is rapidly evacuated and held at a pressure below 0.05 mm of mercury by the vacuum pump. Water vapor evaporates from the frozen serum to be trapped as ice in the condenser, the rate of evaporation is sufficient to keep the serum frozen throughout the process of desiccation. The containers are sealed without breaking the original vacuum. Storage for prolonged periods should be at refrigerator temperature. The light porous residue of serum solids quickly and completely dissolves in distilled water to regenerate a serum the potency of which is not detectably different from the original serum. This procedure has been termed the "lyophile" process.¹²

The rates of deterioration of lyophile serums under various conditions are at present under investigation. Sufficient data are available, however, to show conclusively that potency is much better preserved in this than in liquid form. Striking examples have been published by Eagle, Strauss and Steiner¹³ and by Boerner and Lukens,¹⁴ who have shown that lyophile guinea-pig complement at refrigerator temperatures undergoes no detectable deterioration for ten months and has definite advantages over liquid complement for the Wassermann laboratory. Pooled human adult serum, lyophile

12 Although here used in a somewhat special sense the term "lyophile" is not new but is widely used in colloid chemistry to denote the affinity of a colloid for the liquid in which it is dispersed. The serum proteins preserved by this method maintain their original affinity in this respect, and in consequence they exhibit a remarkably rapid rate of dissolution.

processed and kept at icebox temperature for seventeen months, has been effectual in prophylaxis against measles and in the reversal of positive Dick tests. Lyophile convalescent measles and mumps serums after one year of storage at icebox temperatures have also been effectual in prophylaxis against these diseases.

Lyophile serum may be restored to liquid form by the addition of distilled water to one-half or even to one-fourth the original volume. This concentration is of considerable practical advantage, particularly in the routine intramuscular administration of the serum to children, since less painful injections of smaller volumes of liquid are thus made possible.

The Philadelphia Serum Exchange was established at the Children's Hospital of Philadelphia in the spring of 1934. Its purposes were to make available in and about Philadelphia human serums of known value, to investigate the usefulness of such serums in lyophile form, and to explore the possibilities of new or unrecognized values of human serums made possible by current advances in immunology and explicitly by the lyophile process. Because of our preoccupation with the application of the lyophile process, practically all serums distributed from the exchange have been in this form.¹⁵

The methods used for the collection of serums have been somewhat similar to those employed by other large serum centers such as have existed for some time in Detroit and Chicago. The cooperation of the Department of Public Health of Philadelphia has made it possible to approach through their own physicians patients discharged from the Municipal Hospital for Contagious Diseases and from the Philadelphia General Hospital. After permission of the family physician has been secured, these individuals are invited in person or by mail to act as donors and are offered a small fee for their blood. Healthy adults for pooled adult serum are secured through the social service department of the Children's Hospital. It has been practicable to bleed a healthy adult to the extent of 200 cc. about once a month. A careful history is taken of all donors, especially with reference to previous infectious disease. The donors are bled at the Children's Hospital or, when this is impracticable, in their homes.

The blood is collected in 400 cc. pyrex centrifuge bottles. Fitted on these bottles is a two-holed rubber stopper through which pass two glass tubes, one 2 inches and the other 3 inches long. To the 2-inch tube is attached a piece of rubber tubing 18 inches long, this tube contains a cotton plug and to its end is attached a hard rubber mouthpiece for suction. To the 3 inch glass tube is attached an 18 inch rubber tube, to the other end of which is fitted a "Luer-lock" adapter. A 2 inch No. 18 gage needle will give an adequate flow of blood when aided by the reduced pressure caused by the mouth suction and causes the donors little pain.

At the end of the bleeding the suction is stopped, the tourniquet is released about twenty seconds later and the needle is then withdrawn. Enough blood may then be milked from the tube to which the needle is attached for the performance of the Wassermann or Kahn test. After the bleeding, the rubber stopper with the bleeding and suction tubes attached is removed from the

bottle. The neck of the bottle is flamed and then closed with a solid rubber stopper, which is sterile. In order to give added protection a piece of sterile lead foil is then placed over the solid stopper and pressed down close to the side of the bottle. A number of bleeding outfits, i. e., the perforated stopper with rubber tubing attached, and centrifuge bottles, are kept on hand and are put up and autoclaved in packets.

The blood after collection in centrifuge bottles is stored over night in the refrigerator. The clot is then "rimmed," the bottle centrifuged and the serum removed with sterile precautions. This is best done by aspiration with negative pressure in a dust-free room. The serum so obtained containing erythrocytes is recentrifuged, and aspiration is repeated without disturbing the red cell sediment. The serum is not mixed with serum from other donors for pooling until a negative Kahn report has been received and until a sterility test has shown the absence of gross contamination and of pathogenic bacteria.

The work of pooling and processing was done at the beginning in the department of bacteriology but for the past two years has been conducted at the Mulford Laboratories of Sharp & Dohme through the courtesy of the director, Dr. John Reichel, and Mr. John S. Zinsser, president of Sharp & Dohme. The serum obtained on any given day is transferred to pyrex bottles and rapidly frozen in a bath of Dry-Ice in Methyl Cellosolve. The frozen serum is stored in a refrigerating vault at from -12 to -15 C until serum from thirty to ninety donors has accumulated. All is then thawed, mixed and filtered through a Berkefeld W filter.¹⁶ The filtered serum is distributed sterily into the final containers and there frozen and lyophile processed. Sterility tests are conducted on the filtered serum in accordance with the requirements of the National Institute of Health, and the serum is not released until sterility has been demonstrated.

The lyophile containers are stored in an icebox at the Children's Hospital until required by physicians. A second distribution center has been maintained at the Abington Memorial Hospital by Dr. John Eiman. The serum is regenerated for use by injection of sterile distilled water into the container. Since the serum contains no chemical bacteriostatic agent, the regenerated serum should not be allowed to stand for longer than an hour before administration. The redissolved serum is given by intramuscular injection.

The lyophile human serum prepared by this routine and regenerated appears turbid.¹⁷ Examination under the darkfield microscope reveals that this turbidity is due to aggregated and coalesced lipid droplets.¹⁸ To avoid any possible danger of capillary embolism due to these lipid aggregates, lyophile serum has not been administered intravenously in the work recorded in a paper to be published.

Lyophile human serum four times concentrated has however been used by Hughes, Mudd and Strecker.¹⁹

16 The filters are tested by forcing air through the immersed and thoroughly wetted filter (Mudd, Stuart, and Rivers, T. M. Filtrable Viruses, Baltimore: Williams & Wilkins, 1928). Those used allow air bubbles to pass when air pressure reaches 14 pounds per square inch.

17 In this respect human lyophile serum differs from lyophile horse serum, which regenerates to form a clear or only slightly opalescent solution. Other biochemical differences in the lipids of human and horse serum have been noted (Theorell, H. Studien über die Plasmalipide des Blutes, Biochem. Ztschr. 223, 1, 1930).

18 The microscopic appearance resembles that of aggregated and coalesced chylomicrons as shown by Ludlum, Taft and Nugent. The Chylomicron Emulsion, J. Phys. Chem. 35, 269 (Jan.) 1931.

19 Hughes, J., Mudd, Stuart and Strecker, E. A. Reduction of Increased Intracranial Pressure by Concentrated Human Lyophile Serum. Tr. Am. Neurol. Soc., 62d meeting, June 1936. Arch. Neurol. & Psychiat. to be published.

15 A more economical practice in other human serum centers would doubtless be to use lyophile serum only for storage or shipping of serum in excess of current requirements or when concentration is important thus saving the cost of lyophile processing.

and by McGuinness and Stokes²⁰ for the purpose of reducing cerebrospinal fluid pressure, and for this purpose the serum must be given intravenously. To prepare lyophile human serum for intravenous use the foregoing routine is modified. The pooled serum in large volumes is processed without filtration and is then regenerated. The turbid regenerated serum is clarified by passage under two atmospheres of air pressure through a Berkefeld V filter (such a filter testing at about 6 pounds). This clarified serum is then refiltered to ensure sterility through a Berkefeld W (14 pounds) candle and is distributed into final containers and again lyophile processed.²¹ The volume of serum filtered should be as large as practicable in proportion to the size of the filters, in order to minimize losses by adsorption and occlusion in the filters. This doubly filtered, doubly processed serum redissolves to a clear or opalescent solution in as little as one-fourth its original volume of distilled water, and on intravenous administration has the desired clinical effect of reduction of cerebrospinal fluid pressure and increase of arterial blood pressure.¹⁹

Serum for therapy in scarlatina has been and could be prepared for intravenous administration should the advantage of the intravenous route justify the expense of processing and double filtering. It is perhaps worth pointing out that the procedure outlined for preparing lyophile serum for intravenous use does not require low temperature cold storage facilities. The serum is first processed in a container of the size required for the bleedings of that day. It may then be stored in an ordinary refrigerator until required or until sufficient for a large pool has accumulated. The serum is then regenerated, clarified and refiltered and may be used intravenously or intramuscularly in the liquid form or distributed into individual containers and lyophile processed for later use.

Mention may be made of the precautions against accidental transfer of syphilis in this use of human serum. Only serums from Kahn-negative donors are used. The serum is Berkefeld filtered. Finally one of us (H. E.) has shown that *Spirochaeta pallida* does not survive lyophile processing. Rabbit chancres were emulsified, shown to be infectious for rabbits, and lyophile processed, the residue was reemulsified and injected intratesticularly into six new rabbits. These rabbits showed no signs of syphilis, and after a year four survivors were found to be susceptible to the same strain of *Spirochaeta pallida*. There has therefore been a triple safeguard against accidental transmission of syphilis.

The extremely favorable clinical results in prophylaxis and therapy obtained with lyophile serums will be reported in a later paper.⁷

SUMMARY

The clinical usefulness of human serums has been considerably broadened by the development of methods for their preservation and concentration. Convalescent serum may be collected at times of epidemic prevalence and held until needed. Donors may be specifically immunized and their serum harvested for later use. Pooling on a large scale, for the purpose of augmenting polyvalence is facilitated.

²⁰ In cases of hydrocephalus in babies intravenous injections with refiltered lyophile serum concentrated four times have been made. The resulting reduction of intracranial pressure may be of value in certain cases of the communicating type of hydrocephalus.

²¹ The idea of clarifying the turbid serum and reprocessing was adopted from the procedure of Elser, Thomas and Steffen.^{11c}

The most distinctive advantages of the procedures outlined possibly are in increasing the practicability of the use of serum of healthy adult donors. Such adult serum collected in large pools and properly preserved is proving extremely effective in the prophylaxis of infectious diseases of childhood.

Concentration has the general advantage of reducing the volume of serum to be injected. A special use of four times concentrated human serum in reducing cerebrospinal fluid pressure is set forth in another paper.¹⁹

THE CLINICAL INVESTIGATION OF AN IMPROVED CRYSTALLINE INSULIN

PRELIMINARY REPORT

M. PAUL MAINS, MD

AND

CLARENCE J. McMULLEN, MD

Resident in Medicine and Attending Physician, Respectively,
Cook County Hospital
CHICAGO

Clinicians have long felt the need for a slower and more prolonged action of insulin in diabetic patients to simulate the normally functioning pancreas in maintaining a more constant level of blood sugar. The rapidity with which insulin is absorbed and the short duration of its action often produce marked fluctuations in the blood sugar during the twenty-four hour period. Various modes of insulin administration have been tried, as well as various insulin compounds.

This study deals with the observations in the clinical use of an improved crystalline insulin as to its rate of absorption and its duration of effect in diabetic patients.

The material used was a solution of improved crystalline insulin developed by Dr. Melville Sahyun of Detroit.¹ A solution of the improved crystalline insulin cannot be distinguished in appearance from that of regular insulin. Our supply of this preparation was kept at room temperature for four months, with no decrease in potency. In this we confirm Dr. Sahyun's observations. Over a period of four months no untoward reactions, either local or general, were noted following the injection of the product, nor did any patient note any increase of discomfort over regular insulin.

TYPE OF PATIENTS

This series consisted of twenty-two cases admitted to the surgical diabetic service in the Cook County Hospital and three admitted to the medical service for diabetic management. Of the patients in the surgical service, there were fifteen with complaints which did not complicate their diabetic management, namely, four had arteriosclerotic feet, three had practically healed ulcers on the legs or feet, three had simple fractures, three had cataracts, one slight inflammation of a toe, and one a surgical operation, a perineorrhaphy, two and a half weeks previous to our study of her case. The remaining seven surgical cases presented disorders complicating the diabetic management: three presented

From the Diabetic Service, Cook County Hospital.

¹ From a personal communication received from Dr. Melville Sahyun. We have the following information: "The improved crystalline insulin is dissolved in dilute hydrochloric acid and made up to 40 units per 1 cc. in 0.1 per cent trisresol and 1.6 per cent glycerol and sterilized in the usual manner. Trisresol is added as a preservative and glycerol to render the solution isotonic. Such or similar substances are added to all preparations of crystalline insulin on the market. Dilutions of this improved crystalline insulin have been subjected to 40°C. for seven months. No loss in potency was observed at the end of that period."

gangrene of a foot, two an infection of the stump following amputation, one multiple furuncles, and one an occipital carbuncle

Ages varied from 26 to 74, ten were males and fifteen were females

PROCEDURES

Blood sugar tests were made by the micromethod of Folin, the samples being drawn at 7 30 and 11 a m and at 2, 5 and 10 30 p m Daily twenty-four hour urine specimens on each patient were tested qualita-

Chart 1—A an average of all the blood sugars in a group of eleven patients on each type of insulin B an average of all the blood sugars of two patients receiving one dose of insulin daily C an average of all the blood sugars of the remaining nine patients, those receiving two doses of insulin a day Note the slower absorption of the improved crystalline insulin and its prolonged action resulting in lower fasting morning blood sugars

tively for sugar with Haines' solution, and, if positive, the percentage of sugar was determined by Benedict's method

The diet of each patient remained as nearly constant as possible throughout the course of blood sugar study on that patient Diets were standardized as shown in table 1 Breakfast was served at 8 a m, dinner at 11 30 a m and supper at 4 30 p m In addition, 100 Gm of a 9 per cent fruit was left at the bedside to be eaten about 8 p m Thus there was a more stringent test on both types of insulin by having a liberal allotment of carbohydrate for the evening meal and further by giving the patient 9 Gm of carbohydrate

Chart 2—One of the patients included in chart 1 B She was 74 years of age and was known to have had diabetes for five years. She was admitted January 7 with a fractured femur Recovery was uneventful She was on diet 3 Her chart shows the slower absorption of the crystalline insulin

at bedtime, tending to raise the blood sugar level at 10 30 p m and the next morning Insulin was administered from five to fifteen minutes before the meals

Two experiments were made on two groups of patients The first was to compare the relative efficacy of regular insulin and improved crystalline insulin The second was to observe the effect of replacing multiple daily doses of regular insulin with a single large dose of crystalline insulin

EXPERIMENT ONE

To compare the relative efficacy of the two types of insulin, curves were plotted for eleven patients already stabilized on regular insulin These patients were subsequently stabilized on equal doses of crystalline insulin administered at the same hours, their diets remaining unchanged, and further determinations were made The eleven patients were not selected but were taken in order of admission and included conditions complicating and not complicating their diabetic management, nine were on two doses of insulin a day and two were on one dose They were on either diet 2 or diet 4, as explained in table 1

The series included a total of 280 blood sugars, 164 with the patients on regular insulin of various pharmaceutical companies and 116 on improved crystalline insulin There was, however, such variability of the daily blood sugar curve in so many cases even though uncomplicated and regardless of the type of insulin used, whether regular or crystalline, that comparisons of single days' curves, or even the curves of several days, on any one patient might not result in accurate conclusions Apparently there are factors other than

TABLE 1—Standardized Diets

| Diet No | Carbohydrate | Protein | Fat | Percentage of Carbohydrate Allotted to | | | | Calories |
|---------|--------------|---------|-----|--|--------|--------|--------|----------|
| | | | | Breakfast | Dinner | Supper | Hourly | |

| Crystalline insulin | | | | | |
| Number of determinations | 28 | 20 | 21 | 21 | 21 |
| Average blood sugar | 176 | 220 | 173 | 163 | 164 |

diet and insulin that vary the blood sugar, such as sympathetic nervous disturbances, the functions and dysfunctions of other endocrine glands, alimentary absorption, and infection Thus the daily curve on any one patient might remain fairly constant for several days and be followed by a radically different curve presumably owing to one or more of these intercurrent factors For this reason it was assumed that an average of all the blood sugar levels at each of the five times during the day of all eleven patients while on each kind of insulin should show the activity of that preparation better than one or two individual curves

Potency—An average of all the blood sugars with patients on regular insulin was 182.6, on improved insulin 182.2 This fact, plus the ability to keep patients aglycosuric, proves the new insulin to be equally efficient Since the two types of insulin are equally potent, any differences in their action can be attributed to differences in their rates of absorption

Insulin Reactions—During the entire course of this investigation only five instances of insulin reactions were noted, in none of which did the patient ever

become comatose. One patient was subject to very frequent reactions with regular insulin, coma striking him almost immediately and before he would have time to summon aid or take any carbohydrate, prodromal symptoms were entirely absent. On crystalline insulin this patient had two reactions, one following his omission of the evening nourishment. In neither case did he lose consciousness, but his tongue felt so thick that his speech was unintelligible, although he was able to summon nurses and ask for some sugar. This appar-

Chart 3—One of the patients included in chart 1 B. Note the fairly level blood sugar maintained by the crystalline insulin after its period of delayed absorption. This patient was a Negress aged 55 who was on diet 4. She was known to have had diabetes for several years and had been attending the diabetic clinic. She had arteriosclerosis of the legs and feet.

ently slow onset of hypoglycemia with crystalline insulin allows the patient ample time to ingest carbohydrate to forestall further reduction in the blood sugar level and thus prevent coma. None of the patients, except the one just mentioned, required any treatment for the hypoglycemia, the reactions being so mild as to cause very little discomfort.

Delayed Absorption—Chart 1 A, showing the blood sugar averages from table 2, clearly demonstrates the slower absorption of crystalline insulin, a dose given immediately before breakfast is not absorbed quickly enough to lower the blood sugar by 11 a. m. But after this sharp rise due to delayed absorption the blood sugar for the remainder of the day is maintained at a fairly constant level.

Chart 1 B is the average blood sugar curve in two uncomplicated cases on one dose of regular insulin for two or three days, then on the same dose of crystalline insulin for a like period. A much lower fasting, as well as a much higher 11 a. m. blood sugar while on crystalline insulin, is again apparent.

Chart 1 C, the average curve of the remaining nine cases, those receiving two doses of insulin a day, at breakfast and at supper, also showed the slower absorption of crystalline insulin by an increase of the blood sugar from 7:30 to 11 a. m. and from 5 to 10:30 p. m.

Delayed absorption is likewise shown in chart 2.

Duration of Effect—Chart 1 shows that the effect of regular insulin is worn off by 2 p. m. and thereafter the blood sugar rises until 5 p. m. The new insulin is still active, as evidenced by a lowering of the blood sugar during this period. While with regular insulin (chart 1 B) the blood sugar dropped 20 mg% from 5 to 10:30 p. m., it dropped 25 mg% with crystalline insulin, again, during the night, while the blood sugar remained level with regular insulin, there was a further drop of 5 mg% with crystalline insulin.

In chart 1 C, as pointed out in the section on delayed absorption, the 5 p. m. dose of regular insulin brought

an immediate drop in blood sugar, the new insulin, because of its slow absorption, allowed a slight rise. Since the carbohydrate content of breakfast and supper are approximately equal, this rise undoubtedly would have been much higher, paralleling the 11 a. m. rise, had not the breakfast dose of crystalline insulin still been active. Despite the fact that the 10:30 p. m. average was slightly higher with crystalline than with regular insulin, the prolonged action of the former caused a lower 7:30 a. m. blood sugar.

Level Blood Sugar Curves—The ability of improved crystalline insulin to maintain a more nearly constant blood sugar level after the period of initial delay in absorption was demonstrated in chart 1 A. It is also shown in chart 3 of a patient who was given only 10 units of insulin each morning, the amount necessary to prevent glycosuria. In accordance with hospital routine, this dose was given with the breakfast. Had it

TABLE 3—Rate of Absorption

| Slow Absorption | | Fast Absorption | |
|-----------------|-----------------------|-----------------|------------------|
| Number of Cases | Complication | Number of Cases | Complication |
| 5 | Arteriosclerotic feet | 2 | Gangrene of feet |
| 2 | Medial cases | 2 | Infected stumps |
| 1 | Postpericarditis | 2 | Carbuncle |
| 3 | Simple fracture | | |
| 3 | Cataracts | | |

been given an hour earlier, the sharp rise at 11 a. m. would have been avoided and a more level blood sugar curve maintained throughout the day. But since we were using an entirely new type of insulin and had no previous clinical experience with it to guide us in its use, we confined our studies to its effect on the blood sugar under constant conditions and not to its possibilities in producing the ideal level blood sugar curve.

Rate of Absorption—The rate of absorption seems to be very dependent on some factor in the body, possibly the pH . In this series of cases those who showed quick absorption of the morning dose of crystalline insulin as evidenced by a blood sugar lower at 11 a. m. than at 7:30 a. m. were grouped together. Another group was made up of those whose blood sugar rose in

Chart 4—A woman aged 45 had had a painless ulcer on the right heel six months before admission. She was known to have had diabetes for eight years and was on diet 2. There was an immediate larger drop in blood sugar following 30 units of regular insulin than following 70 units of crystalline insulin.

spite of the dose of crystalline insulin at 8 a. m. The average daily dose and the average single dose of insulin in the two groups were the same. These two groups arranged as in table 3 clearly show that those whose response was rapid are the ones having an active and severe infection, while those showing slower absorption were the uncomplicated diabetic cases.

This observation was made on patients receiving small or moderate doses of insulin, not over 40 units per dose. Even with much larger doses of the new insulin there was an 11 a. m. rise in 33 per cent of the determinations in uncomplicated cases. The immediate

drop in the remaining determinations probably was due to the prolonged action of the preceding large dose

Further studies of the effect of complications on the rate of absorption, with frequent determinations of the carbon dioxide combining power of the blood as an index of acidosis and of the rate of sedimentation of erythrocytes as an index of the severity of infection, might prove illuminating

EXPERIMENT TWO

Five patients receiving two or three doses a day of regular insulin, totaling from 30 to 80 units, were put

Chart 5—A woman aged 54 had a small ulcer on the right leg which healed with out difficulty. On diet 4 she showed adequate control of her blood sugar and no glycosuria on one daily dose of crystalline insulin

on a single large dose of crystalline insulin. These patients had complaints not complicating their diabetic management. There was no dietary change during the experiment.

The substitution of crystalline insulin for regular insulin caused no loss of control of blood sugar and consequently no glycosuria. We did not find it necessary to give supplementary doses of regular insulin to maintain this stability.

The resulting curves confirmed the observations noted in the average curves. The charts of patients receiving the three largest dosages of insulin are worthy of analysis.

Charts 4, 5 and 6 show the curves of patients receiving 50, 60 and 80 units of regular insulin daily in divided doses. Delayed absorption of crystalline insulin is shown by the fact that small doses of regular insulin produced a larger drop in blood sugar from 7:30 to 11 a.m. each day than was produced by doses of crystalline insulin from two to three times as large. In fact, following the crystalline insulin there was often the rise at noon, as noted in the average curves. With crystalline insulin there was a universal drop in the blood sugar from 11 a.m. to 2 p.m. which was not present when regular insulin was administered, even with a noon dose, as in chart 4. Thus crystalline insulin is slower in absorption; the peak of its action not being reached till six hours after injection, i.e., about 2 p.m.

While the blood sugar at 10:30 p.m. with one daily dose of crystalline insulin is often high, owing to the liberal carbohydrate content of the evening meal, to the nourishment taken at 8 p.m. and to the slow absorption of the insulin, there is usually a large drop in the blood sugar over night, whereas with regular insulin there is an invariable rise even with a supper dose. The constancy of this difference in the two preparations is striking. The regular insulin in cases of moderate or severe diabetes does not remain effective over night,

while the nocturnal effect of crystalline insulin in lowering the blood sugar is marked. Apparently a single dose of crystalline insulin shows prolonged action for twenty-four hours or more.

It is noteworthy that there was not a single insulin reaction nor any discomfort to the patient following the administration of daily large doses of crystalline insulin. Even though the patient in chart 6 had a fasting blood sugar of only 103 mg. on the morning of May 8, he was given 60 units of crystalline insulin without any symptoms of hypoglycemia. At no time was there glycosuria.

The convenience and decreased discomfort accompanying a single daily dose of crystalline insulin in preference to multiple doses of regular insulin are highly acceptable to diabetic patients. The use of crystalline insulin in this respect merits further clinical study.

SUMMARY

The improved crystalline insulin used in this investigation was perfectly stable at room temperature.

The data obtained in comparing regular and crystalline insulins show them to be equally potent, as demonstrated by the daily average of all blood sugars.

An average of 280 blood sugar readings in complicated and uncomplicated diabetes shows slower absorption and more prolonged action of improved insulin.

Severe infections or an acidosis seems to favor a more rapid absorption of crystalline insulin.

Delayed absorption prevents insulin reactions following the injection of large doses of improved insulin, even when the fasting blood sugar is low.

The single morning dose apparently remains in effect during the succeeding night, as shown by the lowering of the blood sugar between 10:30 p.m. and 7:30 a.m.

One daily, large dose of crystalline insulin may adequately control the blood sugar of patients requiring two or more doses of regular insulin daily and maintain the patients aglycosuric.

Chart 6—A man aged 65 had had diabetes for six years. A small ulcer on the plantar surface of the right foot healed quickly. Even though his fasting blood sugar on May 8 was only 103 he had no insulin reaction following a dose of 60 units of the crystalline insulin. This patient was on diet 2.

Our work was a comparative study and no attempt was made to improve the blood sugar curve with crystalline insulin.

The improved crystalline insulin is worthy of further clinical study.

Chewing the Food—Such rules as that each mouthful should be chewed a given number of times are too arbitrary to be permanently helpful. A more rational rule is that each mouthful should be chewed until swallowing is entirely unobscured.—Sherman H. C. Food and Health New York, Macmillan Company, 1934

Clinical Notes, Suggestions and New Instruments

MYELOPHTHISIC ANEMIA IN A CASE OF CARCINOMA OF THE STOMACH

EDGAR F. KISER, M.D.

Associate Professor of Medicine, Indiana University School of Medicine
AND

B. D. ROSENAK, M.D., INDIANAPOLIS

This report of a patient having carcinoma of the stomach with an unusual form of anemia has been prompted by a report of two similar cases made recently by Dr. Theodore R. Waugh.¹

Clinicians are familiar with the usual picture of anemia due to gastric carcinoma. The vast majority of cases demonstrate the typical picture of so-called secondary anemia due to chronic blood loss. The factor of impaired nutrition enters into the production of minor degrees of anemia in those cases before actual loss of blood begins. It is thought that in cases in which there is an actual achylia gastrica this factor also plays an important role in disturbing the normal hematopoiesis. In most cases in which there is a more or less severe degree of anemia in cancer of the stomach, the etiologic factor of most importance is the chronic loss of blood from the ulcerated surface of the lesion itself. The degree of metastasis, according to Crohn,² has nothing to do with the severity of the anemia unless bone marrow metastases have occurred, as in the case herewith reported. However, Eusterman and Balfour³ point out that there is a correlation between the degree of anemia and the extent of involvement of the stomach, and consequently the blood picture has some value as a prognostic sign. The severity of this type of anemia in cancer of the stomach varies greatly. The red blood cells may number 2,000,000 or less, but most cases at the time of diagnosis will be found to show a red cell count of from 3,500,000 to 4,000,000, and a hemoglobin of 40 to 70 per cent. The color index is always below 1 in this type of anemia. There is no feature of this blood picture to enable differentiation from the anemia due to chronic blood loss from any other cause.

A less common blood picture in cancer of the stomach is that which closely resembles Addisonian anemia. This condition has been seen on a number of occasions in the past few years and always has aroused considerable debate as to diagnosis. In most of these instances in which a macrocytic anemia with a high color index is found, certain clinical features of the case will point the way to the correct diagnosis. Often the hematologic studies alone will not suffice, and only a thorough study of gastric contents, with determination of enzymes and a careful roentgen examination of the stomach, will reveal that such a case of anemia is due to or accompanied by carcinoma of the stomach. In several instances we have had such cases on liver therapy and obtained excellent reticulocyte response. In one case, seen three years ago not only were the blood picture and reticulocyte response present but the patient also presented the clinical picture of posterolateral sclerosis. At present, three years after a sleeve resection of an adenocarcinoma of the stomach, he is apparently well and maintains a satisfactory blood picture on iron alone. It is never possible under such circumstances to feel absolutely certain that a single individual does not have both lesions. Nor can one dismiss the thought that the carcinoma has played some part in destroying the intrinsic gastric hematopoietic factor and is, in fact, the etiologic background for what is essentially a true pernicious anemia.

A third and much less common form of anemia engages our attention at present—so-called myelophthisic anemia, a severe grade of hemolytic anemia occurring in diseases which destroy the bone marrow. Metastatic carcinoma is an occasional cause of this type of anemia. Cancer of the breast, thyroid and prostate are most apt to metastasize to bone, but not infrequently this occurs in cancer of the stomach. For some

unaccountable reason, bone marrow metastases may occur without producing this bizarre blood change, but when it does occur there should be no difficulty in classifying it. The significant morphologic changes in the blood include a marked diminution of red blood cells, correspondingly low hemoglobin content, marked anisocytosis and poikilocytosis, and a high percentage of polychromatophilic cells and nucleated forms. Myelocytes are frequently found in the circulating blood. Thus in these cases a very rapid destruction of blood cells, particularly the red cells, occurs and there is a marked increase in the number of immature cells present in the circulating blood. Waugh found an increased red cell fragility in his cases and felt that this factor played some part in their rapid destruction. The fragility test in the case herein presented was entirely normal. The mechanism of the destruction of the erythrocytes in these cases is unknown. Waugh states that a "toxin" produced by the cancer cells may be the hemolytic factor. The logical explanation for the abundance of young cells in the blood is that a compensatory stimulation of the uninvolved areas of bone marrow occurs. This may be due to mechanical or chemical irritation of the marrow neighboring the metastatic nodules. Pepper and Farley⁴ state that in the terminal stages of this type of anemia an actual aplasia of bone marrow occurs with an absolute cessation of hematopoietic activity. It is not often that an individual lives until such bone marrow destruction extends sufficiently to produce an absolute aplasia. However, it is conceivable that a considerable degree of aplasia of bone marrow may be produced in cases of widespread carcinomatosis. It seems reasonable, therefore, that an aplastic element might also play a part in the picture of myelophthisic anemia, in that destruction of marrow occurs out of proportion to compensatory activity of uninvolved hematopoietic tissue.

Another feature of the present case which may or may not support the foregoing theory is the terminal disappearance of platelets from the circulating blood. This may be due to a failure of formation or to a rapid destruction of these elements by the same toxin that destroys the red blood cells.

REPORT OF CASE

A white man, aged 38, a plumber, first consulted his physician Nov. 24, 1935, when he complained of mild backache, weakness and fever. At this time he was sent to bed and treated for influenza. However, he did not respond to treatment, continued to lose weight, became weaker, and developed dyspnea. He was seen in consultation in his home December 24, one month after the onset of his illness. He was found to be cachectic, profoundly weak, very short of breath, and definitely flushed.

Physical examination revealed his temperature to be 101 F and there were signs of fluid in the left side of the chest. Examination of the abdomen disclosed nothing. The patient did not appear to be profoundly anemic. At this time the diagnosis of tuberculosis and possibly tuberculous pleurisy was made, and he was sent to a hospital.

At the time of the initial visit, no significant data concerning family illnesses could be ascertained, and the patient stated that his health had been excellent until the onset of the current illness.

When admitted to the hospital, he was found to be mildly jaundiced and his spleen was definitely palpable. There were no gastro intestinal symptoms. The nails and mucosae appeared very pale, but his skin did not show a marked anemia. His pulse was 140, respiration 30, and temperature 100.

Laboratory examinations on the day of admission showed the urine to be entirely normal and the Wassermann and Kahn reactions to be negative. A roentgen examination of the chest revealed a general increase in density of both bases, a small amount of fluid in the left base, and an area of increased density in the right lower lobe, which latter the roentgenologist stated had the appearance of a small metastatic nodule but which he said was probably due to an area of exudation. In this instance, caution prevented the making of a brilliant roentgen diagnosis.

There was very little response following two transfusions of 500 cc of citrated blood. Several blood counts were made, but the one made December 28 is representative hemoglobin

2 Crohn B B. Affections of the Stomach. Philadelphia W B Saunders Company 1927

3 Eusterman G B and Balfour D C. The Stomach and Duodenum. Philadelphia W B Saunders Company 1935

4 Pepper, O H P, and Farley D L. Practical Hematology. 4th Edition. Philadelphia W B Saunders Company 1933

28 per cent, or 421 Gm, erythrocytes 1,690,000, anisocytosis marked, poikilocytosis marked, nucleated cells frequent, polychromatophilia marked, reticulocytes 11 per cent, leukocytes 6,000, polymorphonuclears 6 per cent, small lymphocytes 17 per cent, large lymphocytes 26 per cent, staff cells 33 per cent, basophils 3 per cent, metamyelocytes 10 per cent, myelocytes 3 per cent, monocytes 2 per cent, platelets too few to count, color index 0.82, coagulation time 10 minutes, bleeding time 45 seconds, fragility of red cells on initial hemolysis 0.44 per cent sodium chloride, on complete hemolysis 0.34 per cent sodium chloride. Clot retraction occurred within twelve hours. Red cell sedimentation was 0.1 mm per minute (normal, according to the method of Rourke and Ernste). The van den Bergh test gave a delayed positive reaction, indirect positive reaction. Quantitative serum bilirubin was 0.5 mg. Blood cultures were negative.

As stated before, the patient did not respond to blood transfusions but declined very rapidly and died on the fifth day after admission to the hospital.

Autopsy showed an adenocarcinoma of the stomach situated on the posterior wall near the lesser curvature. The lesion was 6 cm in diameter and protruded about 1 cm into the lumen. The surface of this lesion was not eroded or ulcerated. The nodes along the lesser curvature and those throughout the mesentery as well as those following the aorta and its branches were markedly enlarged and firm. The liver was enlarged and was studded with metastatic nodules. The spleen was enlarged but was not involved in the metastatic process. The left adrenal gland showed numerous firm nodules throughout. The lower lobes of both lungs contained microscopic areas of carcinomatous infiltration. There were very few areas that might have been large enough to cast the shadow seen on the x-ray films. Unavoidable circumstances made it impossible to obtain bone marrow specimens, but such sections would only have added corroborative information to this case, which completely demonstrates the myelophthytic type of anemia in a patient with rapidly metastasizing carcinoma arising in the stomach.

SUMMARY

There are two common forms of anemia seen in cancer of the stomach. One of these is a simple form of secondary anemia due to chronic blood loss and undernutrition, the other is one that bears much similarity to true pernicious anemia.

A case of carcinoma of the stomach presented a rare form of anemia due to metastatic involvement of bone marrow. The mechanism of this so-called myelophthytic anemia is not definitely understood but presents elements of rapid destruction of red blood cells, a compensatory stimulation of hematopoietic activity, and probably some degree of aplasia.

RECTAL STRICTURE COMPLICATING DELIVERY

REPORT OF A FATAL CASE

Cecil D. Gaines, M.D. and James F. McDowell, M.D.
Birmingham, Ala.

A review of the recent literature fails to reveal any articles dealing with the problem of rectal stricture complicating delivery, yet the great mass of rectal disorders that the average physician meets in general practice should warrant giving a severe rectal stricture the respect that is its due in regard to pregnancy and the delivery of that pregnancy. We feel that the presence of rectal stricture in the pregnant patient should be regarded with grave apprehension.

The principal point in the relation which the presence of a stricture might have on the delivery of the pregnancy depends entirely on the degree of the stricture. A history of constipation over a long period of time associated with the presence of "pencil sized" stools should warn the obstetrician of impending difficulty. Small strictures or "bands" in which there is no decrease in the size of the stools or in which there is no decrease in the size of the rectal canal are of no consequence and may be disregarded. But when there is a definite thickening of the rectal wall and particularly of the rectovaginal septum a complete study of the condition should be made preferably before the onset of labor.

REPORT OF CASE

S. V., a white woman, aged 19, admitted to the labor room in active labor, dated the onset at about twenty hours before admission with rupture of the membranes thirty minutes before admission. The past history was essentially negative except for the presence of "rectal trouble" for several years. She had had no antepartum care, owing principally to the fact that she had never menstruated. She stated that she was not cognizant of being pregnant. On examination she was found to be in very active labor and her general condition did not appear to be good. External pelvic measurements were within normal limits, no internal measurements were taken. Routine rectal examination revealed a very tight rectal stricture which would admit the index finger with the greatest difficulty for a distance of about 1 inch (2.5 cm). There was involvement of the entire wall of the rectum, extending as far as the finger could reach. There was a definite thickening of the rectovaginal septum. Internal hemorrhoids protruded with each labor pain. The fetus was in the left occipito anterior position with fetal heart tones well heard in the left lower quadrant of the abdomen. Approximately three and one-half hours after admission the fetal head was crowning, but the patient seemed to be making little if any progress. She was prepared for delivery. Tucker-McLean forceps were applied and a medio-lateral episiotomy done, there was marked bleeding from the incision as the result of the unexpected large size of the vulvar varicosities. Strong traction with the forceps failed to bring the head any farther down. Version and extraction was then decided on as the most advisable procedure. Except for some difficulty in replacing the head the version was comparatively easy, but after the delivery of the chin the obstruction was sufficient to stop the extraction. With a great deal of traction the head was finally delivered rather suddenly. The child was a normal full-term living male weighing 6 pounds 7¼ ounces (3,062 Gm). The episiotomy was repaired in spite of the patient's semishocked condition, and she was transferred to the ward when it was thought safe. She reacted only once from the shock and died approximately five and one-half hours after delivery.

Postmortem examination revealed a moderate amount of thick dirty brown fluid with a fecal odor in the pelvis and dependent portion of the upper part of the abdomen. In the rectovaginal excavation there was a transverse laceration through the pelvic peritoneum and underlying anterior wall of the rectum with a direct communication of the lumen of the latter into the peritoneal cavity. There was a stricture of the rectum two phalanges above the anus with a considerable narrowing of the lumen of the remaining portion of the rectum, 8.4 cm above the anus was a laceration of the anterior and lateral portions of the upper part of the rectum, with an opening communicating directly with the peritoneal cavity. The mucosa of the rectum and sigmoid colon was irregularly scarred and covered with scattered deep purple hemorrhagic areas. The wall was moderately indurated and the lumen definitely narrowed. A diagnosis of chronic ulcerative colitis and sigmoid diverticulitis was made.

It was apparent from the clinical history, physical examination, difficulty in delivery, and the postmortem examination that the direct cause of death in this case was the presence of a severe rectal stricture. The method of handling the delivery would have undoubtedly been cesarean section, with probable sterilization, had it been realized beforehand that the dystocia offered by the rectum could have been so great. We feel that in this type of case a section is definitely indicated and that if the diagnosis is made prior to the onset of labor a great deal of danger may be averted.

SUMMARY

1 In a fatal case of rectal stricture complicating delivery the dystocia caused by long-standing chronic ulcerative colitis was sufficient to cause rupture of the rectum with delivery of the head.

2 Cesarean section is indicated in cases of severe rectal stricture.

3 The history of "rectal trouble" should be studied thoroughly during the antepartum care of the pregnant woman.

Special Article

THE IMPORTANCE AND ADVANTAGES OF PRESCRIPTION WRITING IN MEDICAL PRACTICE

E FULLERTON COOK, PH M

Chairman of the Committee of Revision of the Pharmacopeia
of the United States

PHILADELPHIA

This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U S Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—Ed

In connection with the Eleventh Revision of the United States Pharmacopeia, containing the new official *materia medica*, a series of articles are appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. The authors have been asked to express their opinions, without bias or influence, concerning the most effective treatment of certain diseases. Although their attention has been called to the official list of medicinal substances, they will be free to disregard these agents if in the interests of efficacious therapy other drugs should be mentioned. Any remedies that come to light through these writings can then be considered and investigated with the view of possible inclusion in the Pharmacopeia through "interim revisions."

THE SELECTION OF U S P MEDICINES

The therapeutic agents included in the latest Pharmacopeia were selected by a subcommittee consisting of eighteen physicians and five pharmacists. The physicians were those named by the medical members of the U S Pharmacopeial Convention, primarily for their special qualifications for deciding the scope of the U S P so far as it represented therapeutic agents. The pharmacists contributed information concerning the extent of use of substances but were specially responsible for pharmaceutically necessary items such as were needed to manufacture or test the quality of the official medicines.

The principle governing the selection of medicines was exclusively that of therapeutic merit, as demonstrated through biologic and clinical experience. At the time of selection, even such questions as their status with respect to trademark or patent control were not to be considered. That the new Pharmacopeia might adequately represent the best therapeutic agents known to modern medicine, the former official list was carefully reviewed and about 100 substances eliminated as obsolete or unnecessary. Then all outstanding items in the newer *materia medica* were studied and fifty-four therapeutic agents were added to the official list.

THE U S P CONTAINS MOSTLY SINGLE THERAPEUTIC SUBSTANCES—NOT COMBINATIONS

Another guiding principle influenced the selection of the U S P XI titles. This was a theoretical ideal which the committee has maintained, namely, that only simple or basic substances or at least only concentrates of these, and no polypharmaceutical mixture, should receive Pharmacopeial recognition. This is based on the teaching that the physician should be free to exercise skill and judgment in the selection and combining of each

medicine, that it may exactly meet the needs of his individual patient. It also affords an opportunity to the physician to employ one drug of known physiologic activity, if he so wishes, or to combine with it an adjunct or such adjuncts as he believes desirable.

A PRESCRIPTION SHOULD BE DISTINCTIVE

While the ideal of medical practice is to use a single therapeutic agent of known physiologic value, it is often advisable to employ a suitable vehicle and to vary this so that the medicine may be distinctive. This applies to all forms of medication, such as liquids, powders, capsules and ointments. A pleasant flavor, an odor that suggests something other than a medicine, an added color are all legitimate enhancements to a prescription and make the medicine less likely to be duplicated. Those who deal with the sick are conscious of the influence of suggestion, a belief in the physician and his treatment is a powerful influence for relief and cure.

ADVANTAGE OF COOPERATION BETWEEN THE PHYSICIAN AND THE PHARMACIST

If the physician in practice is unfamiliar with suitable flavors, colors and vehicles, he has a tendency to order ready made preparations rather than to write a prescription containing the ingredients desired. Other factors that sometimes lead to "ordering" in place of "prescribing" are complexity of the pharmaceutical problem involved or lack of information as to dosage, solubility, chemical reactions and other factors.

In these strictly pharmaceutical problems the skilled pharmacist can often help the physician. He can also supply information concerning manufactured medicines, and cooperation with a competent pharmacist will frequently prove beneficial to the patient.

The intensive training of the physician and the elaborate machinery for preparing, standardizing, checking and distributing medicinal substances are all animated by the needs of a patient. To meet this situation there comes the physician, skilled in diagnosis, familiar with the most effective methods of treatment and having at his command a knowledge of the action of medicinal substances and knowing when they are indicated. But his medical skill frequently cannot function effectively if there are not available the carefully prepared and standardized ingredients for his prescriptions, already produced by expert pharmacists, chemists, bacteriologists or biologists, and made available through the pharmacist in the hospital or the community.

IMPORTANCE OF THE SCIENTIFICALLY CONTROLLED MANUFACTURING LABORATORY

In the background there must stand today the manufacturing laboratories, with efficient equipment and rigid control over every step of manufacture. These must produce standard inorganic and organic chemicals such as ether, potassium iodide and sodium salicylate, complex synthetics such as arsphenamine, biologicals such as diphtheria antitoxin and rabies vaccine, biologically standardized pharmaceuticals, including preparations of digitalis and pituitary, sterile products for parenteral administration and the hundreds of other needed chemicals and pharmaceuticals.

The trained pharmacist serves as a liaison officer in the hospital, the medical center and the community. His specialized knowledge concerning the available medicines should be of inestimable value to the physician in both the selection of medicines and their combination.

THE PRESCRIPTION FOR THE INDIVIDUAL

The prescription written for the individual patient is an important link in a perfected service. An original prescription shows evidence of professional skill and is not a product with which the patient is already familiar through its display in the type of medicine store where no professional knowledge is present and where such standards must necessarily be low.

The latter situation is worthy of serious consideration, for the patient is likely to question the justification for a doctor's fee when it results in what may appear to be a "patent medicine" type of treatment. Physicians are also realizing that the patient is almost certain to recount his or her experience when talking to friends, perhaps to the discredit of the doctor. Even the naming of such trademarked medicines under these circumstances often leads those who hear the discussion to buy the same medicine to relieve self-diagnosed symptoms. The alarming increase in the use of hypnotics, without medical advice, illustrates this danger.

The use of abbreviated official titles written into a prescription and with a "non rep" order controls the situation, while the suggestion to "buy it at the drug store" opens wide the door to self medication.

OFFICIAL MEDICINES NOW LARGELY USED

In proposing the use of official medicines on prescriptions it is not being suggested to physicians that they seriously modify the present-day custom of most doctors. In a scientifically conducted survey of the actual ingredients used by physicians in their prescriptions during 1931-1932, a study covering typical communities throughout the United States and including 121,294 prescriptions, Gathercoal¹ reported that 65.19 per cent of the ingredients in these prescriptions were official in the U. S. P. X, 7.92 per cent were in the National Formulary, 16.05 per cent were proprietary specialties and 10.84 per cent were unofficial items. About the same time the author of this paper found by a study of the catalogues of physicians' supply houses that a preponderant proportion of the ingredients used in their formulas were official in the U. S. P.

The Pharmacopeia of the United States was founded by physicians in 1820 as a therapeutic guide to the profession. It has endeavored to maintain that position for more than a hundred years. Its preparations were the basis for the teaching of therapeutics in medical schools for almost a century and now they constitute the large majority of those therapeutic agents recommended by the American Medical Association in *Useful Drugs* as a present-day therapeutic guide for medical schools.

PHYSICIANS AND THE PHARMACOPEIA

The Pharmacopeia invites the physicians of the country to assist in maintaining it as a reliable guide to the medical profession in the field of therapeutics. If items now official are unreliable they should be deleted, as important new remedies are developed these should find a place in the Pharmacopeia by "interim revision."

It is believed that, with a study of the ingredients official in the new Pharmacopeia especially when supplemented by the National Formulary tablets, ampules and elixirs of U. S. P. drugs, including such preparations as Elixirs of the Bromides, of Barbitals, Phenobarbital and Aninopyrine respectively, and the

Sprays and Jelly of Ephedrine, physicians will find a wide range of medicines for practically every therapeutic need.

OFFICIAL MEDICINES IN HOSPITAL TREATMENT

Emphasis should also be placed on the restriction of routine hospital treatment to official medicines whenever possible, since this has been demonstrated to be a policy which is scientifically and economically sound.

PRESCRIPTION WRITING BY HOSPITAL INTERNS

This program for the hospital has within it another possibility of far-reaching significance. It is realized that the medical student has little opportunity in his crowded curriculum to become familiar with official titles or even to gain practice in prescription writing. Insufficient information and training in these two fields as well as the use of certain types of hospital formularies and lack of cooperation between the house and visiting medical staffs help to explain the failure to write more prescriptions for official medicines. This is being recognized by a number of hospitals, and both medical and surgical interns are being given regular training in the use of official medicines and in prescription writing. The appreciative response, where this course has been well conducted, is gratifying and is apparently justifying itself by the increased efficiency and ability of the younger physicians having this added training. The medical staffs of many hospitals have developed their own "formulary" as an aid in the efficient and economic use of medicines within the hospital. The prescriptions in such a "formulary" should never be given by numbers, as this practice has led to both carelessness and mistakes. In the compiling of such a "formulary" the official titles of drugs, chemicals or preparations, or their official abbreviations, should be used so that the younger physicians on the staff may become increasingly familiar with these established medicines.

THE PRICE OF A PRESCRIPTION

The price of a prescription is no small item for consideration in the total cost of medical care. It should be the basis for a complete understanding and must be established on a sound and economically correct foundation.

It is proper that the patient should pay for the medicine and that it should not come out of the physician's fee, for that is not economically sound and leads to numerous abuses. Many physicians today are being persuaded to start the practice of office dispensing. There are conditions in which this is justified, as in a country district where there are no prescription filling facilities, but that it introduces the possibility of many complications must be conceded, and most physicians return to prescription writing as soon as financial pressure is relieved.

However, to return to the price to be charged for the prescription when the pharmacist is called on to utilize his professional skill and equipment in supplying the medicine ordered by the physician or when he has prepared the medicines beforehand in his laboratory, using his training and equipment, there is justification for including a reasonable professional fee in the price to be charged the patient.

THE REFILLING OF PRESCRIPTIONS AND THE GIVING OF COPIES

An argument sometimes advanced against the writing of prescriptions is based on the belief that the patient often continues the use of the medicine long after it

¹ Gathercoal, E. N. The Prescription Ingredient Survey published by the American Pharmaceutical Association.

was intended by the physician by having the original prescription refilled and by even giving copies of the prescription to friends

If a physician prefers that the prescription shall not be refilled except on his order, it is the common practice to add to the prescription the abbreviation "non rep" and this injunction will be honored by the pharmacist

This "non rep" order should never be printed on a prescription blank. It has a different significance when written on the prescription by the physician. The pharmacist can assist by attaching a special label to the filled prescription indicating that it is nonrefillable. In such cases "a copy" of the ingredients should not be placed on the package

SUMMARY

The welfare of the patient is often aided by the administration of a properly selected medicine. A distinctive prescription, written for the needs of a specific patient and using official drugs or preparations whenever these are available, is desirable.

The skilled professional pharmacist can often be helpful in the selection and combination of medicines.

The judicious use of the "non rep" order on prescriptions and the employment of official titles will assist in the control of objectionable self medication.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER Secretary

MODEL J DIATHERMY AND COAGULATOR ACCEPTABLE

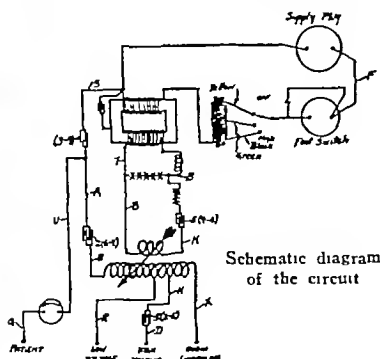

Manufacturer The Liebel-Flarsheim Company, Cincinnati

This machine is recommended by the manufacturer for medical and surgical diathermy. The unit is mounted in a cabinet of walnut finish and is equipped with three voltage taps low, high and medium. The unit weighs about 60 pounds.

At the request of the Council the manufacturer submitted data concerning tests of the machine for power input and out-

Model J
diathermy and
coagulator

put and for its spark gap and transformer temperature rise. The results recorded in the data were in agreement with the observations of the Council's investigator and were in conformity with the standards for diathermy machines previously established by the Council.

The unit was tested for seven months in a clinic acceptable to the Council and the investigator reported that the machine coagulates desiccates and fulgurates satisfactorily and develops sufficient heat for use in medical diathermy.

In view of the favorable report, the Council voted to include the Model J Diathermy and Coagulator in its list of accepted apparatus.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT
PAUL NICHOLAS LEECH Secretary

SMALLPOX VACCINE (From Chick Chorio-Allantoic Membrane)-LILLY

Eli Lilly & Co requested Council consideration of its smallpox vaccine made by using chick chorio-allantoic membrane instead of the usual calf lymph. The firm supplied the following statement of the method of preparation:

Chick embryos of about fourteen days are used. After sterilizing the surface of the eggshell a minute opening is drilled and the chorio-allantoic membrane inoculated with sterile seed vaccine virus from a syringe the needle of which is introduced through the shell puncture. The opening is sealed with paraffin and the inoculated egg returned to the incubator. After an incubation period of seventy-two to ninety-six hours the chorio-allantoic membrane is exposed, harvested and tested for sterility. Only sterile membranes are used in the preparation of the vaccine. These are pooled into a sterile container and a 50 per cent glycerin diluent added. Grinding to a very fine homogeneous emulsion is effected by a high speed electric grinder. Sterility safety and potency tests are run. After filling the vaccine into capillary tubes sterility and potency are checked.

The firm holds that this method of preparation eliminates the hazard of bacterial contamination and gives an improved preparation of uniform potency, diminished virulence and immunizing quality at least as high as that of the vaccine prepared from calf lymph.

In support of the claim of equal potency with that of calf lymph the firm presented the following comparative chart of potencies of the finished product as filled into the capillary tubes and placed on the market:

Comparative Filling Potency Chick Embryo and Calf Smallpox Vaccine

| Item and Lot Number | 1 100 | 1 1 000 | 1 3 000 | 1 10 000 |
|---------------------|-------|---------|---------|----------|
| Chick Vaccine | | | | |
| No. 922716 | 5+ | 3+ | 1+ | 1+ |
| No. 922715 | 5+ | 4+ | 3+ | 3+ |
| No. 922713 | 5+ | 4+ | 2+ | 2+ |
| No. 922714 | 5+ | 4+ | 2+ | 2+ |
| No. 922712 | 5+ | 3+ | 2+ | 1+ |
| Calf Vaccine | | | | |
| No. 913966-2 | 4+ | 3+ | Not run | 2+ |
| No. 913966-3 | 4+ | 3+ | Not run | 1+ |
| No. 916388-1 | 4+ | 4+ | Not run | 2+ |
| No. 916388-2 | 4+ | 3+ | Not run | 2+ |
| No. 918191-1 | 4+ | 4+ | Not run | 2+ |
| No. 902731-4 | 4+ | 4+ | Not run | 3+ |

As evidence for the clinical effectiveness of the product, the firm presented the following reports of its use by Drs. Frank D. Ryder and Carl J. Lund of Minnesota, who have kindly given permission for their use in this preliminary report.

SMALLPOX VACCINATION Grand Island Public School System November 1935

| | |
|---------------------------------|-------------|
| Number Vaccinated | 3 356 |
| Elementary Schools | 1,968 |
| Junior and Senior I Students | 1 388 |
| | 3 356 3 356 |
| Reactions | |
| Positive takes entire system | 2 492 |
| Negative—no takes entire system | 864 |
| | 3 356 |

| | |
|--|-------|
| The percentage of positive reactions in elementary schools (up to 7th grade) | 91.3% |
| Immune reactions same age group | 1.9% |
| Inherited immunity—no reactions | 6.8% |
| In Junior and Senior High Schools (7th grade to 12th grade incl.) the percentage of positive reactions | 50.1% |
| Immune reactions same age group (students who had been vaccinated within seven years and those who had had smallpox) | 49.9% |

Dr. Lund reported as follows:

It may be of interest to know that I recently vaccinated 118 pupils in our local grade and high school.

I used your chick chorio-allantoic membrane smallpox vaccine and had 100% takes on those who had primary vaccinations.

I used the multiple pressure method (40-50 pressures).

The Council considered the evidence offered for Smallpox Vaccine (from Chick Chorio-Allantoic Membrane)-Lilly to be favorable but insufficient as yet to justify its acceptance for inclusion in New and Nonofficial Remedies. The Council therefore postponed consideration of the product to await the development of further confirmatory evidence of its value.

SELENIUM POISONING IN THE UNITED STATES

Selenium poisoning, formerly called "alkali disease," has been discussed before in our editorial columns.¹ It was first recognized in 1857 by Madison² on the Missouri River in what is now Gregory County, S. D., among a squadron of horses. Mayo³ reported its occurrence in certain sections of Kansas in 1890-1891, and the Wyoming Agricultural Experiment Station observed it in horses in Carbon County, Wyo., in 1893. Peters⁴ in 1897 and 1904 announced its occurrence among cattle, horses, pigs and chickens in Boyd County, Neb., and Lipp⁵ described it in South Dakota in 1921. In 1928 Kurt W. Franke of the South Dakota State College of Agriculture at Brookings learned that animals consuming vegetation growing on particular areas developed "alkali disease." He found that grain which had been grown on "alkalied" farms and fed to white rats was very toxic and he attributed the injurious effects to a definite toxic constituent or group of constituents. In 1931 Henry G. Knight of the Bureau of Chemistry and Soils, United States Department of Agriculture, suggested that traces of selenium absorbed by plants from the soil might be responsible. Analysis of a sample of toxic wheat by W. O. Robinson revealed a content of from 10 to 12 parts per million of selenium. These important discoveries have stimulated much investigation, especially by the Bureaus of Chemistry and Soils, Plant Industry and Home Economics of the Department of Agriculture at Washington and the agricultural experiment stations of South Dakota and Wyoming. The evidence obtained definitely incriminates selenium and indicates that the so-called alkali disease of live stock may be due to traces of selenium in indigenous grains and forage.

Selenium, with an atomic weight of 78.9, is a relatively rare allotropic element having many of the physical and chemical properties of sulfur and tellurium. It is widespread in the earth's crust, occurring in small quantities in the combined and free state, mostly associated with native sulfur, sulfate or metallic iron. It combines with many elements, such as oxygen, hydrogen, fluorine, chlorine and bromine, and most metals. Its chief commercial usefulness lies in the glass, copper, steel, ceramic and photographic industries and in the process of vulcanizing rubber and insuring noninflammability to electric cords.

The "alkali" disease is prevalent in the North Central Great Plains of the United States, causing losses among cattle, horses, pigs, sheep and chickens as the result of the ingestion of selenium-bearing vegetation growing on arid or semiarid grazing lands and farms. Cereal-producing areas are involved, for the most part certain regions in South Dakota and Wyoming, and it is thought that North Dakota, Kansas, Montana, Nebraska, Colorado and New Mexico may be affected.

The Cretaceous and Eocene geologic formations, deposited about 120 million and 60 million years ago, are the selenium-bearing strata in this section of the country, particularly the Pierre formation, where from traces to 100 parts per million of selenium have been found. Soils derived from such strata and vegetation growing on such soils contain selenium in varying quantities. The total area of soils concerned is enormous, but not all the vegetation growing on them is toxic. Byers⁶ believes that seleniferous areas exist in at least four continents. If leaching has not occurred, all soils derived from pyritiferous parent materials contain selenium. However, water in these toxic areas contains the element only in traces. The investigations of the United States Bureau of Agriculture and of the South Dakota State College of Agriculture have revealed the presence of selenium in foods in the "alkalied" areas, such as milk, eggs, corn, wheat, barley, rye, string beans, lettuce, cabbage and turnip leaves in amounts varying from 0.3 to 150 parts per million of selenium, data which indicate the gravity of this problem, at least locally.

The toxicity of selenium compounds toward bacterial, plant and animal life varies with the ionic state. Selenite is more toxic than selenate, and reduced selenium is almost nontoxic. Selenium and arsenic possess similar toxic effects. Selenium is readily absorbed but is rapidly reduced by all life. The toxicity of vegetation depends on its selenium content, and the absorptive power of plant life for selenium depends on the degree of rainfall, leaching, weathering, composition of the soil, the geological outcrop on which the plant material grows, the species of plant, and the amount of available sulfur or sulfate in the soil. Any soil containing more than 0.5 part per million of selenium and

6 Byers H. G. Selenium Occurrence in Certain Soils in the United States with a Discussion of Related Topics. Technical Bull. 483 U. S. Dept. Agriculture August 1935.

any vegetation containing 5 parts per million is potentially dangerous⁷. As shown by the studies of Franke,⁷ in the plant the selenium toxicant exists in the protein fraction in an unknown organic combination and may be removed by mercury bichloride precipitation.

Whether animals are fed with inorganic selenium compounds or with the natural plant toxicant, the pathologic and symptomatic features resemble closely those encountered among animals in the toxic areas. Necrosis and regeneration of the hepatic parenchyma with extensive periportal fibrosis and resulting cirrhosis combined with hemorrhages and secondary inflammatory reaction in the liver and kidneys are the primary pathologic features. Reduced selenium is found in the liver and spleen, and compounds of selenium are found in all tissues, secretions and excretions. Cattle, horses, sheep and pigs show erosions of the ends of the weight-bearing bones, with hoof abnormalities that considerably impair locomotion. Malaise, anorexia, stunted growth, loss of body hair, loss of weight, emaciation, impairment of reproductive power and severe anemia develop, to be followed by exhaustion, toxemia and death. The poisoning may be acute, in which case it is called blind staggers. Chickens show a decided impairment of fertility, if the eggs hatch the young do not live long, and monstrosities occur among them frequently. It is significant that Franke succeeded in producing similar monstrosities in chicks by the injection of selenium salts into fertile eggs. The symptoms encountered experimentally in the guinea-pig and the white rat do not essentially differ from those in other animals.

Even if removed from the toxic range and fed wholesome forage, selenized cattle do not usually recover their normal health. The stunting of growth in calves is distinct and continued, and in cattle the damage to the kidneys and liver seems to be permanent. Franke noted that rats fed on toxic grains for as short a period as ten days showed a lack of recovery, growth disturbances and typical pathologic changes even when fed a control diet for 165 days.

An evaluation of soil treatment with sulfates is indicated especially in the light of the work of Hurd-Karrer,⁸ who observed that an adequate sulfur content of the soil may reduce the toxic influence of selenium.

"Alkali disease" is essentially an agricultural and veterinary problem of local concern. The danger to public health seems to be relatively slight, owing to the low content of selenium in the great portion of commercial crops and the high dilution of toxic grains in the general market. So far human selenium poisoning has not been reported in the toxic areas, but because of occurrence among various kinds of animals there is no reason to believe that man is immune. This aspect of the problem is now under investigation.

EPIDEMIC AMEBIC DYSENTERY

Studies of the Chicago outbreak of epidemic amebic dysentery of 1933 are now accumulated in a special bulletin¹ issued by the United States Public Health Service. The epidemiology, which constituted one of the most important aspects of the general situation, is reported in considerable detail. This epidemic was the first recognized water-borne outbreak and the only known extensive epidemic of this disease in a civilian population. Approximately 8,500,000 out of town visitors came to Chicago during the period of the epidemic, with resulting congestion of the downtown hotels and public eating places. Two large neighboring downtown hotels having to some extent a common water supply were chiefly involved. During the epidemic period approximately 160,000 persons had contact with these hotels. During the year from June 1, 1933, to June 30, 1934, an obviously incomplete total of 1,409 cases were brought to light. More than two thirds of those infected were out of town visitors to the city. The active onset of symptoms generally occurred after the visitors had returned to their homes, hence amebic dysentery so acquired was reported from more than 400 cities scattered in forty-three states, the territory of Hawaii and three Canadian provinces. The average interval between exposure and report of illness to the Chicago board of health was three months, the long delay being due to various factors. There was no evidence that any active focus existed other than that of the two hotels, but in one of the hotels the general incidence of infection was higher than in the other. Except at the beginning and end of the epidemic period, from June 1 to Dec. 31, 1933, infections were being spread almost continuously but with marked variation in the risk of exposure at different times. In general, the more prolonged the exposure at the hotel, the greater was the hazard of infection. Ten per cent of those apparently infected within the hotels gave no record of eating at either of the two hotels, and almost all of these stated specifically that they did not eat in the hotel at which they stayed. All, however, presumably drank water there. The age, occupation and socio-economic status of the hotel guests infected corresponded with those of visitors to these two hotels. Evidence was not found of variations in sex susceptibility. The incidence of carriers among employees of the two hotels was respectively 37.8 and 47.4 per cent. Repeated examinations of employees indicated that infestations with *Endamoeba histolytica* were taking place during the epidemic. Vigorous measures directed to the prevention of the spread of infection by carriers among food handlers were ineffective. The opinion was reached that the principal if not the sole means of spread of this epidemic was through water polluted in one of the hotels. A contributing factor, however, was the progressively increasing number of carriers among

employees and probably among guests who remained for longer than the average stay

Study of the engineering features of the epidemic was particularly productive of results. Thus, it was found that pressure variations in the different parts of a hotel plumbing system are more marked than is customary in a city street distribution system, because of the height of the building, hence hazards from lack of pressure or negative pressure are more liable to occur inside the building than outside. Two major sanitary defects were found, namely, cross-connections between sewer 2 and the condensers and a sewer leak round a wooden plug over the cooled water tank in the same hotel. Several important points were brought out in the investigation. Regulations for building cross-connections, in order to be enforced, must be backed by an adequate and experienced inspection force, there is great need for education of engineers, architects, designers, equipment manufacturers, installation artisans and operating personnel having to do with water supply, drainage and the sewage disposal systems of large buildings relative to the hazards of cross-connections, the secondary use of water in an institution may involve potential hazards of pollution, and therefore any secondary system should be kept entirely separate from the main water supply system. The installation of new or additional plumbing fixtures in a building without providing for the extra load on the drainage system may cause serious flooding of the sewers. Sewers operated under pressure require special construction, especially of joints, to prevent leakage. Plumbing defects of any character should be promptly and effectively repaired. Water storage tanks should be effectively covered.

The clinical aspects of the epidemic also were studied, as far as allowed by the wide geographic distribution. That the disease is not exclusively a tropical disease has been effectively impressed by the outbreak. It is therefore a clinical entity that must be considered in differential diagnosis in all regions. Not alone may epidemic cases be encountered, but endemic infections have been found to be more widespread than generally supposed. It may simulate a variety of clinical conditions, such as colitis, appendicitis, malignant conditions of the colon and surgical conditions involving the rectum. Specific therapy proved to be remarkably effective in the epidemic cases, but nonspecific measures were usually disappointing and surgical intervention often disastrous.

The thoroughness of the investigation of this widespread epidemic furnishes a notable example of what should be done in preventive medicine. It can scarcely be doubted that, had the knowledge existed and had such knowledge been put into effect prior to the disaster of 1933, more than a thousand serious illnesses would have been prevented. It is certainly important that the engineering and sanitary information gleaned from this epidemic be applied immediately in order to prevent a similar epidemic from arising whenever conditions of

unusual crowding occur. The engineering and inspection laws relative to big buildings should be revised if necessary and immediately enforced not only in Chicago but in all cities in which such conditions might possibly arise.

Current Comment

RADIO HEALTH DRAMAS RESUMED

Beginning October 13, the American Medical Association and the National Broadcasting Company resume the health dramatizations broadcast during 1935-1936 under the title *Your Health*. The first program will be broadcast October 13 and will be the thirty-second nation-wide dramatized program broadcast by the American Medical Association. Details as to the time of day, the stations to which the program will be available, and the topics will be found under Association News in this issue of *THE JOURNAL*. These dramatized radio programs have been described in the *American Medical Association Bulletin*.¹ The dramatic technic has met with the approval of the profession and of the public. Mail from our audiences did not cease with the termination of the first series of dramatized broadcasts in May. Throughout the summer letters have continued to come referring to programs given several months prior to the date of the letter and requesting information supplementing the broadcast. This evidence that the dramatized technic not only interests at the time but makes a lasting impression justifies continuance of this more expensive and more difficult technic in preference to the didactic talk. The presentation of dramatized radio programs in cooperation with the National Broadcasting Company is an instance of how the radio networks are prepared to cooperate in educational broadcasting. Physicians do not always see eye to eye with the radio in matters of advertising and with relation to restrictions on discussion of some medical topics. The cooperation of the radio in educational programs of this kind is an evidence of willingness to grant expensive radio time and network facilities in the public interest. It should lead to a better mutual understanding between the medical profession and the radio industry, which will be helpful in the solution of their mutual problems. Putting a radio program on the air is only the first step. The radio as an advertising medium is valuable, but it does not stand alone. Neither does it stand alone as an educational medium. The radio must be supplemented with other forms of publicity. The program *Your Health* will be delivered to the Red network and the Pacific network of the National Broadcasting Company and will be available to approximately sixty stations. These stations may take it or leave it. The local decision may often be influenced by evidence of a local demand. The local medical societies have an opportunity to aid in popularizing the program by calling attention of their patients to it, both individually and collectively, through newspaper announcements and other means that may suggest themselves.

¹ Bauer, W. W. *Dramatizing the Health Message*. A. M. A. D.C. 30:97 (Oct.) 1935. *Evaluating Health Dramatizations*. Ibid. 31:114 (May) 1936.

in the local situation. An attractive announcement card which may be hung in the office of the physician is in preparation and will be sent gratis on receipt of a postcard or letter addressed to the Bureau of Health and Public Instruction, American Medical Association, 535 North Dearborn Street, Chicago. The greatest measure of success for this educational project can be achieved only through the highest degree of cooperation between the American Medical Association and local medical societies and auxiliaries.

RADIO BROADCASTS

Health Dramas to be Resumed October 13

The American Medical Association and the National Broadcasting Company present the second series of dramatized health broadcasts under the title *Your Health*, beginning October 13. The first broadcast in the new series will be the thirty second dramatized cooperative broadcast under the title *Your Health*. The theme for 1936-1937 will differ slightly from the topic in the first series which was "medical emergencies and how they are met." The new series will be built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night, to serve the American people in sickness and in health."

The program will be on the Red network and Pacific network of the National Broadcasting Company. The following stations are those to which the program is available:

New England States

WEEI—Boston
WTIC—Hartford
WJAR—Providence
WTAG—Worcester
WCSH—Portland Me

Middle Atlantic States

be induced to broadcast the program if it receives evidences of local interest. The committee on education or other appropriate committee of the local medical society might take this matter up with the station management and tender cooperation in giving the program local publicity.

The topics are announced monthly in advance in *Hygeia*, the Health Magazine, and three weeks in advance in each weekly issue of *THE JOURNAL*. The topics and speakers for October are as follows:

October 13 What to Do for Blind Children W. W. Bauer, M.D.
October 20 Arthritis Morris Fishbein, M.D.
October 27 Help for the Deafened W. W. Bauer, M.D.

The time of the broadcast is Tuesday afternoon at 5 o'clock eastern standard time (4 o'clock central time, 3 o'clock mountain time, 2 o'clock Pacific time).

ALABAMA

The Prevalence of Poliomyelitis—A total of 335 cases of poliomyelitis with twenty-five deaths has been reported in Alabama between January 1 and September 11, according to the state department of health. The incidence has been heaviest in Jefferson County with seventy-one cases. Next in order are Lauderdale with forty-seven cases, Morgan with thirty-eight, Colbert, twenty-eight, Franklin, twenty, Cullman, eighteen, Limestone, sixteen, Lawrence, twelve, Madison, eleven, Blount, eight, and Marengo and Marshall, five each. Scattered cases of one or two each appear in other counties. In twenty of the sixty-seven counties of the state no cases of the disease have been reported, they are Chambers, Lee, Macon, Russell, Barbour, Henry, Houston, Coffee, Covington, Crenshaw, Butler, Wilcox, Monroe, Conecuh, Washington, Clarke, Choctaw, Sumter, Greene and Perry. The opening of rural schools was postponed in northern Alabama, eastern Mississippi and southwest Georgia, the New York *Times* reported September 4 with the tentative date of opening set at September 21. The *Times* also reported, September 10, that during the preceding week 183 cases were recorded throughout the country, Illinois leading with thirty cases and California being second with twenty-five. There were twenty cases in New York.

ARIZONA

Memorial to Dr. Harlow Brooks—The first "Harlow Brooks Memorial Navajo Clinical Conference" was held at Sage Memorial Hospital, Ganado, August 31-September 1. The speakers included Drs. Fred H. Albee, New York, Milo K. Tedstrom, Santa Ana, Calif., William W. Peter, Fort Defiance, medical director of the Navajo service, Joseph Madison Greer, Phoenix, Albert G. Jenner, Milwaukee, Edwin Forrest Boyd, Los Angeles, and Clarence E. Yount, Prescott, moving pictures made by Dr. Joseph B. De Lee, Chicago, Edgar A. Doll, Ph.D., Vineland, N. J., and Dr. Julius S. Weingart, Des Moines, Iowa, were also shown. The conference, to be held annually, is named in honor of the late Dr. Harlow Brooks, New York, who was interested in the work of the Sage Memorial Hospital. Ganado is in the heart of the Navajo reservation.

CALIFORNIA

Personal—Dr. Joseph Pomeroy Widney, member of the class of 1866 of Toland Medical College (now the University of California Medical School) San Francisco, is the subject of a biography now being distributed throughout the state. Dr. Widney, now 95 years of age, was one of the founders and early presidents and first dean of the University of Southern California. The biography was first published in *California and Western Medicine*.

Society News—The San Francisco County Medical Society was addressed, September 15, by Chauncey D. Leake, Ph.D., on "Recent Advances in Industrial Toxicology" and Floyd DeEds, Ph.D., U. S. Department of Agriculture, on "Toxicity of Spray Residues." This was a joint meeting with the section

It should be noted that a station may take the program or not. If a station included in the list is not broadcasting the program *Your Health*, it is possible that the management may

on industrial medicine — At a recent meeting of the San Bernardino County Medical Society the Friedman test in the abnormal states of pregnancy and in early chorionepithelioma were discussed by Drs George D Maner and Edmond M Lazard, both of Los Angeles — The Los Angeles Cancer Society was addressed September 3, by Dr Edwin I Bartlett, San Francisco, on "Cancer of the Breast, with a Five Year Follow-Up of Over 100 Cases and a Discussion on Treatment with Ultimate Results"

CONNECTICUT

New State Epidemiologist—Dr Paul H Brown, for six years health officer of East Haven has been appointed epidemiologist to the state department of health, newspapers report. He will be succeeded by Dr Robert M Taylor now coroner's physician. The change was effective September 1

Summering Physicians Barred from Practice—Physicians licensed and residing in other states but maintaining summer homes in Connecticut cannot care for patients in Connecticut, according to an opinion filed August 3 with the state department of health by Attorney General Edward J Daly. In his opinion, the attorney general said according to newspaper reports "Under the provisions of Section 1121C, cumulative supplement, general statutes of 1935 no such physician can obtain a certificate of registration to practice medicine and surgery in the state inasmuch as he can not be said to permanently reside in this state"

GEORGIA

Dr Hoke Resigns at Warm Springs—Dr Michael Hoke, since 1931 surgeon-in-chief of the Georgia Warm Springs Foundation, Warm Springs has resigned to engage in practice in Atlanta. Dr Hoke graduated from the University of Virginia Department of Medicine, Charlottesville, in 1895. Dr Charles E Irwin, assistant to Dr Hoke, has been named surgeon-in-chief. He is 36 years old and a graduate of Emory University College of Medicine, Atlanta

Dr Fischer Honored—Dr Luther C Fischer, Atlanta, was honored at a birthday dinner given by the staff of the Crawford W Long Memorial Hospital, of which he is president and treasurer. A sterling silver vase was presented to him. Speakers included Drs Odom O Fanning who made the presentation speech, Walter B Emery and Rufus T Dorsey. Dr Fischer in 1925 established the L C Fischer prizes to be awarded through the Fulton County Medical Society, two prizes of \$100 each have been available every year since that time

ILLINOIS

Personal—Dr Hal E Freeman, Willard Mo has been appointed a member of the student health service University of Illinois Urbana — Dr Philip McGinnis has been appointed health officer of Joliet township succeeding Dr Londus Brannon, who resigned after three years' service

Clinical Conference—Physicians of western Illinois will be guests of the McDonough County Medical Society at a clinical conference in Macomb, September 24. Dr Robert S Berghoff, Chicago, will conduct a heart clinic in the afternoon, and ten patients will be presented by local physicians for examination and demonstration. In addition Dr Berghoff will speak on common diseases of the heart, Dr Joseph E F Laibe Chicago on hematuria, and Dr William J Pickett, Chicago, thyroid surgery

Meeting of Bacteriologists—The Society of Illinois Bacteriologists will meet at the Urbana-Lincoln Hotel Urbana September 26. Speakers will include

Ralph E Noble B.S. Chicago Status of Bacteriologic Water Analysis
C A Brandy Urbana Observations on Egg Propagation of Filtrable Viruses
Martin J Prucha Ph.D. Urbana, Sterilization Disinfection Bactericidal and Bacteriostatic
Arthur M Buswell Ph.D. Urbana Anaerobic Fermentations Yielding Combustible Gases
Dr Ernst A Prilman Chicago A Report on the Second International Congress for Microbiology London England 1936

Society News—The McLean County Medical Society was addressed September 10 by Drs Gladys R. H. Dick Evanston on scarlet fever Rosco G Leland director Bureau of Medical Economics American Medical Association economics and the ethics of medicine and William H Holmes Chicago clinical aspects of nephritis — Dr Franklin E Walton St. Louis spoke before the Vermilion County Medical Society September 1 on "Diagnosis and Management of Biliary Tract Diseases" — At a meeting of the St. Clair County Medical Society in Belleville September 2 Dr Vincel Rogers Deakin, St. Louis spoke on Pylitis of Pregnancy. Dr Frank G Norbury Jacksonville addressed the East St. Louis meeting

September 3, on "Neuropsychiatry in General Practice." — Dr William B Serbin, Chicago, addressed the Coles Cumberland County Medical Society, September 10, on "Toxemias of Pregnancy"

CHICAGO

Dr Braasch Will Give Belfield Lecture—Dr William F Braasch, professor of urology, University of Minnesota Graduate School of Medicine, Minneapolis Rochester, will deliver the eighth annual William T Belfield Lecture of the Chicago Urological Society, October 29. His subject will be "Unilateral Chronic Pyelonephritis"

Lectures on Cancer—The cancer research committee of the Chicago Woman's Club announces its annual lectures on cancer, with the following speakers

Dr Max Cutler, October 22 Cause and Cure of Cancer
Dr Harold E Robertson October 29 Rochester, Minn. Scientific Aspects of Cancer
Dr Frank L Rector, Evanston November 5 Cancer A Public Health Problem
Miss Edna Foley, superintendent Visiting Nurse Association Nursing Care of Cancer Patients in Chicago
Dr William W Bauer director Bureau of Health and Public Instruction American Medical Association November 12 Importance of Popular Education on Cancer and Approved Methods of Carrying on Such Education

INDIANA

Personal—Dr Robert A Staff, for three years a member of the staff of the Indiana State Sanatorium Rockville, has been appointed medical superintendent of the Smith Esteb Memorial Hospital, Richmond, succeeding Dr Joseph W Strayer, who resigned to accept a similar position at the William Ross Sanatorium, Lafayette

New Clinical Building at University—Contracts have been awarded for a new clinical building at the Indiana University School of Medicine, Indianapolis and construction is expected to begin soon, according to the state medical journal. The total cost of the building will be about \$550,000, of which the federal government will pay 45 per cent as a PWA project the remainder will be paid by the university through a bond issue. The building, five stories high, will be situated immediately north of the Robert W Long Hospital

IOWA

Graduate Courses—The Iowa State Medical Society will offer graduate courses in Davenport, Waverly, Sheldon, Oska loosa

The first course, devoted to cancer, September 17, and is sponsored by the First, Second and Sixth Councilor Districts, but physicians from other districts are invited to attend, it will be given on Thursdays. The course in general therapeutics and diagnosis given at Davenport will be conducted on Tuesdays the opening lecture was September 15. Meetings at Sheldon will be held on Mondays, beginning September 21 and continuing through November 9. The course on cancer will be presented by the following

Dr Richard H Jaffé Chicago Morbid Anatomy and Physiology of Malignant Tumors
Dr Elexious T Bell Minneapolis Present Status of Cancer Knowledge
Dr Loyd Davis Chicago Malignant Neoplasms of the Nervous System
Dr Gordon B New Rochester Minn Malignant Tumors of the Head
Dr Arthur U Desjardins Rochester Evaluation of Radiologic Diagnosis and Treatment
Dr Owen H Wangenstein Minneapolis Cancer of the Esophagus Stomach and Small Intestine
Dr Erwin R Schmidt Madison Wis Sarcomas
Dr Ruben Nomland Iowa City Cancer of the Skin
Dr Claude F Dixon Rochester Cancer of the Colon and Rectum

Therapeutics and diagnosis will be treated by the following speakers

Dr Samuel A Levine Boston (tentative), Modern Cardiac Therapy
Dr William S Middleton Madison Wis The Barbiturates in the Treatment of Disease
Dr Howard L Beye Iowa City Principles Involved in the Treatment of Fractures
Dr Rollin T Woodyatt, Chicago Diet in the Treatment of Disease
Dr John S Lundy Rochester Evaluation of Intravenous Therapy
Dr Paul A O'Leary Rochester Treatment of Syphilis
Dr Philip S Hench Rochester Diagnosis and Treatment of Arthritis
Dr Percival Bailey Chicago Diagnosis and Treatment of Common Neurologic Lesions Found in General Practice
Dr Warren T Vaughan Richmond Va Evaluation of the Present Knowledge of Allergy
Edward A Doisy Ph.D. St. Louis (tentative) Present Status of Endocrine Therapy
Dr Henry W Meyerding Rochester Fractures
Dr Maurice C Howard Omaha Diagnosis and Treatment of the Anemias
Dr John A Berghoff Omaha Diagnosis and Treatment of Common Skin Disorders
Dr Byrl R Kirklin Rochester Roentgenologic Diagnosis
Dr Norman M Keith Rochester Use and Abuse of Diuretics
Dr Oscar H Plant Iowa City Recent Advances in Therapeutics
Dr Russell M Wilder Rochester Modern Treatment of Diabetes
Dr Everett D Plass Iowa City The Ovarian Hormones in Obstetrics and Gynecology

KANSAS

Health at Kansas City—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 5, indicate that the highest mortality rate (184) appears for Kansas City and for the group of cities as a whole, 96. The mortality rate for Kansas City for the corresponding period last year was 111 and for the group of cities, 94. The annual rate for eighty-six cities for the thirty-six weeks of 1936 was 124 as against a rate of 116 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

KENTUCKY

State Medical Meeting at Paducah, October 5-8—The annual meeting of the Kentucky State Medical Association will be held in Paducah, October 5-8, with headquarters at the Irvin Cobb Hotel. The speakers will include

- Dr Emmet F Horine, Louisville. An Evaluation of Heart Sound Records from a Clinical Standpoint
- Dr Finis M Travis, Frankfort. Treatment of the Different Types of Edema.
- Dr Henry W Cave, New York. Recent Trends in the Surgical Management of Biliary Tract Disease.
- Dr Irvin Abell, Louisville. Relation of Surgery to Diabetes.
- Dr Carlisle R. Petty, Lynch. Management of an Epidemic of Cerebrospinal Meningitis in an Industrial Community.
- Dr Oscar O Miller, Louisville. Pulmonary Abscess and Its Treatment.
- Dr William Barnett Owen, Louisville. Consideration of Complicated Fractures of the Femur.
- Dr Francis M Sherman, Owensboro. Interpretation of Gastric Pain.

Dr John H J Upham, Columbus, Ohio, President-Elect of the American Medical Association will be the speaker at a public meeting Tuesday evening, October 6. The annual oration in surgery will be delivered by Dr DeLou P Hall, Louisville, on "Joshua B Flint, First Professor of Surgery, University of Louisville 1837" and the oration in medicine by Dr John Harvey, Lexington, on "Our Duty to the Art and Science of Medicine." There will be round table discussions Tuesday and Wednesday afternoons on surgery, obstetrics, pediatrics, general medicine, otolaryngology, ophthalmology and psychiatry. A symposium on obstetrics and pediatrics will be presented by Drs Russell E Kinsey, Williamstown, Joseph T Molony, Covington, Orion Leon Higdon, Paducah, Richard G Elliott II, Lexington, and Harry S Andrews, Louisville. At the annual dinner Wednesday evening, Drs James E Paulin, Atlanta, Ga., and Albert M Mitchell, Terre Haute, Ind., will be the guest speakers.

MARYLAND

Illness from Custard Pastries—During the latter part of August twelve persons in Baltimore were ill from eating custard filled doughnuts. Prompt reporting of the outbreak and immediate investigation by the city health department prevented other cases developing. The custard used was made at about 2 a m and allowed to cool in the baking room for about three hours without refrigeration. The doughnuts were then filled with it and offered for sale at about 9 o'clock. Each of the persons made ill by the custard ate from one to three of the pastries bought at about that time and before 11 o'clock each victim was seized with intense pain in the abdomen, vomiting and prostration. The time of onset and the symptoms were almost identical in all the patients, none of whom gave a history of having eaten any additional food or of drinking any beverage, *Baltimore Health News* reported.

MASSACHUSETTS

New Chairman of Medical Board—Dr Francis R Mahony, Lowell, for many years a member of the Massachusetts Board of Registration in Medicine, was elected chairman of the board at a meeting August 28. He succeeds Dr Charles P Sylvester, who resigned on account of ill health.

Society News—The Pentucket Association of Physicians was addressed September 10 by Dr Donald Munro, Boston, on "Responsibility of the General Practitioner in Relation to Common Neurosurgical Conditions", Dr Arthur W Allen, Boston, will discuss "Diseases of the Peripheral Vascular System" before the society, October 8—Drs Richard H Miller and Cadis Phipps, Boston, will address the Worcester District Medical Society in Milford, September 23 on peptic ulcer.

Sir Frederick Hopkins to Give Dunham Lectures—Sir Frederick Gowland Hopkins, professor of biochemistry, University of Cambridge, will lecture at the Harvard Medical

School, Boston, on "The Significance of Catalysis in Biology". The lectures, under the Edward K Dunham Lectureship for the Promotion of the Medical Sciences, will be presented October 6 on "The Catalytic Equipment of Micro Organisms" and October 8 on "The Nature of Biocatalytic Systems in General".

MICHIGAN

Personal—George I Forster, PhD, professor of biology at Olivet College, Olivet, has been appointed bacteriologist to the state department of health. He will be on leave of absence from the college for a year—Dr Edward J Witt, St Joseph, was made an emeritus member of the Cass and Berrien county medical societies at a meeting August 19. Dr Witt is retiring from active practice and plans to leave the city.

New Laboratory Building—A new laboratory building for the state department of health is under construction four miles north of Lansing. A WPA project, the original appropriation for the building was \$111,518 but an additional 10 per cent has been allowed by the government to make up for increases in labor costs. All departments of laboratory work will be carried on in the new structure. C C Young, PhD, Lansing, is in charge of the state department laboratory.

State Medical Meeting at Detroit, September 21-24—The seventy-first annual meeting of the Michigan State Medical Society will be held at the Book-Cadillac Hotel, Detroit, September 21-24, under the presidency of Dr Grover C Penberthy. The guest speakers will include

- Dr Charles Gordon Heyd, New York. Vice President American Medical Association Society and Organized Medicine.
- Dr Dean Lewis, Baltimore. Hormones in Relation to Tumor Growth.
- Dr Cecil S O'Brien, Iowa City. Ocular Symptoms and Signs of Brain Tumor.
- Dr Isidore Friesner, New York. Otolaryngology (round table).
- Dr Fred Wise, New York. Skin Diseases in Their Relation to Disturbances of Other Organs.
- Dr George Herrmann, Galveston, Texas. Further Studies of the Mechanism of Action and of the Relative Effectiveness of the Newer Diuretics.
- Dr Emil Novak, Baltimore. Pseudomalignant and Precancerous Lesions of the Uterus.
- Dr Richard Cannon Eley, Boston. The Control of Measles.
- Dr Albert L Brown, Cincinnati. Treatment of Ocular Inflammations with Increased Intra Ocular Typhoid Antibody Concentration.
- Dr Byrl R Kirklin, Rochester, Minn. Differential Diagnosis of Benign from Malignant Ulcerative Lesions of the Stomach.

There will be symposiums on certain complications of pregnancy, carcinoma of the lung and fractures. Dr Lewis will conduct a special demonstration in traumatic surgery. President's Night will be observed Wednesday evening, September 23, when Dr Penberthy will deliver his presidential address and Dr Henry E Perry, Newberry, will be inducted into the presidency. The Andrew P Biddle Oration will be delivered on this occasion by Dr George W Crile, Cleveland, his subject will be "Comparative Anatomy and Pathologic Physiology of the Adrenal-Sympathetic Complex Relating to the Genesis and Surgical Treatment of Essential Hypertension".

MINNESOTA

Personal—Dr Hobart A Reimann, Minneapolis, associate professor of medicine, University of Minnesota Medical School, was guest of honor at a farewell dinner, August 20. Dr Reimann has been named Magee professor of medicine at Jefferson Medical College, Philadelphia.

MISSOURI

Society News—At a meeting of the South Central Counties Medical Society in Houston, August 6, speakers were Drs Duff S Allen and Carliss Malone Stroud, St. Louis, on differential diagnosis of acute abdominal conditions and allergy respectively. Dr Allen also discussed goiter. The Cass County Medical Society was addressed June 11 among others, by Dr Lotus V Murray, Pleasant Hill, on "Chronic Endocervicitis".

NEVADA

State Medical Meeting—The thirty-third annual meeting of the Nevada State Medical Association will be held in Reno, September 25-26, with headquarters at the Golden Hotel and under the presidency of Dr Richard O Schofield, Boulder City. Speakers on the program will be

- Dr Harold M F Behrman, San Francisco. Modern Concepts in Therapy of Cardiac Diseases.
- Dr Eugene S Kilgore, San Francisco. Some of the Surgeons Circulatory Problems.
- Dr Charles F McEnskey, Los Angeles. Anesthetic Agents and Methods.
- Dr Albert R Da Costa, Reno. Problems in Anesthesia.
- Dr George Warren Pierce, San Francisco. Treatment of Burns and Reconstruction Surgery After Burns.
- Dr Horace C Pitkin, San Francisco. Low Back Pain.
- Dr William W Washburn, San Francisco. When Should Peptic Ulcer Be Treated Surgically?
- Dr John W Chinn, San Francisco. Surgery of the Colon.

Aug 5, 1936

International Congress of Microbiology

At the second International Congress of Microbiology, held in London, more than thirty countries were represented. In his opening address the president, Professor Ledingham, said that the congress was due to the efforts of the Health Section of the League of Nations to reconstitute international scientific meetings, which were interrupted by the World War. They were really a continuation of the congresses of hygiene and demography, the last of which was held at Washington in 1913. But the extraordinary development of bacteriology and microbiology had rendered some subdivision necessary. At the previous congress they worshipped at the shrine of Pasteur. Now they went further back and engraved on their badges Antony van Leeuwenhoek (1632-1723) the Dutch microscopist, who first made a drawing of bacteria.

The congress was divided into eight sections: general biology of micro-organisms, virus diseases in animals and plants, bacteria and fungi, economic bacteriology, medical, veterinary and agricultural zoology and parasitology, serology and immunochemistry, microbiologic chemistry, and specific immunization. The number of papers read reached the extraordinary total of 400.

VIRUSES

The subject of viruses was discussed for two days. Dr A. R. Dochez and others from New York described researches showing the presence of a filtrable virus in the upper respiratory tract of persons suffering from the common cold and influenza. They had demonstrated the activity of this virus by experimentally producing similar diseases in chimpanzees and in human volunteers. Not the typical picture of influenza but one more resembling the common cold was produced.

Dr G. H. Eagles brought forward evidence in favor of a virus cause for rheumatoid arthritis and rheumatic fever. Pericardial and pleural exudates from cases of rheumatic fever and joint fluids and synovial membrane from acute and subacute rheumatoid arthritis yielded suspensions of bodies which in stained preparation and by darkfield examination, were indistinguishable from bodies demonstrable in similar suspensions from recognized virus infections.

CONTROL OF WHOOPING COUGH AND DIPHTHERIA BY SPECIFIC IMMUNIZING REAGENTS

Dr W. H. Park described an investigation in New York to determine the prophylactic value of pertussis vaccine. Though the incidence of pertussis was low among unvaccinated children, a marked reduction was produced by vaccination with from 65 to 88 million bacilli. Professor Madsen of Denmark said that figures from an isolated community, such as the Faroe Islands indicated the value of prophylactic vaccination, especially in decreased severity of the disease. Danish clinicians also agreed that a vaccine used in the first two weeks of the disease had a beneficial effect. Dr Park said that the fall in the incidence of diphtheria following immunization of the population left no doubt as to its efficacy. He had found alum-precipitated toxoid preferably in two or three doses, the best antigen. The duration of the immunity appeared to be long and the few reactions encountered were not severe. Dr R. A. O'Brien of London said that immunization had protected nurses against grave infections when tending severe cases of diphtheria.

VIRUSES AND NEW GROWTHS

Dr Peyton Rous of New York suggested that an association of viruses with cells was responsible for some neoplastic diseases. A tumor of the frog and numerous diseases of the

domestic fowl had proved to be due to viruses. As to mammals the wild rabbits of the Middle West of America frequently had skin papillomas caused by a virus, which in domestic rabbits produced vigorous growths, often metastasizing and on the brink of malignancy. All tumor phenomena could be explained in terms of what was known of viruses, yet it did not follow that the generality of tumors were actually caused by them.

THE MICROBIOLOGY OF CANNED FOODS

Prof F. W. Tanner of Urbana, Ill., said that refrigeration did not destroy micro-organisms but only inhibited their activities. Foods subjected to quick freezing were perishable and should be kept frozen until ready for preparation for the table, if the development of food poisoning organisms was to be prevented. Some 10 per cent of canned meat products and 24 per cent of canned corn and over 50 per cent of canned pineapple harbored viable micro-organisms. The conditions that allowed them to survive should be studied. For ten years factory-canned food had not caused botulism in America, but home-canned foods continued to take their toll each year.

THE MECHANISM OF VIRUS IMMUNITY

Prof J. C. G. Ledingham of London opened the discussion. He said that killed viruses conferred only the most trivial and ephemeral protection, though this might be a subsequent basis for reinforcement by the living virus. Dr E. W. Schultz of Los Angeles stated that it had been established that the virus of poliomyelitis entered the central nervous system by the olfactory nerve. Serum prophylaxis and vaccines had not been proved to be effective, but recent observations indicated that temporary protection might be afforded by previous treatment of the nasal mucous membrane with chemical agents, which tended to diminish the permeability of the olfactory portal. Dr G. W. M. Findlay of London said that more than 1,000 persons had been immunized against yellow fever by injections of immune serum and living virus. Serum from immunized horses produced reactions in from 10 to 15 per cent of cases but human serum produced no serious reactions. Since immunization had been developed, no case of yellow fever had occurred among those exposed to laboratory infections.

Control of the Drug Traffic

A report of the measures taken by the British government to deal with the traffic in dangerous drugs has been issued. It describes the working of the system of control which has been established in this country, in accordance with the Hague and Geneva international conventions over the trade in these drugs, and the action taken in cooperation with other governments to suppress illicit traffic. Narcotic addiction is not prevalent in Great Britain. The total number of known addicts at the end of the year was about 700, of whom about 120 were physicians. In 90 per cent of the cases morphine was the drug of addiction, in 5 per cent cocaine and in 5 per cent diacetyl morphine. In all cases the drug was obtained through legitimate channels. In general the system of import certificates and export authorizations for the control of opium and other dangerous drugs has worked satisfactorily, though in a few cases difficulty has arisen owing to the use of languages other than the official ones of the League of Nations. The sale, prescription and dispensing of dangerous drugs in this country are under stringent regulations. A physician who violates them may have his right to purchase or prescribe such drugs withdrawn.

Safety in Coal Mines

The Royal Commission on Safety in Coal Mines has heard some important evidence as the result of the organized research that has taken place. It has been shown that coal dust can of itself produce explosions, which can be prevented or suppressed by stone dust. In regard to firedamp, Prof R. A. Wheeler stressed the need for research in order to ascertain

details of the characteristics of the elements that constituted danger. Ignition was not instantaneous but occurred after a measurable interval, during which a series of chemical reactions, leading eventually to the production of flame, took place. Firedamp was remarkable for the long duration of the so called lag on ignition. If the nature of the reactions that took place, particularly the primary reaction, could be identified, means of rendering ineffective some of the sources of ignition in a coal mine might be devised. The lag could be considerably delayed by the presence in the air of an inhibitor, the most effective yet discovered being iodine vapor. The dangers of explosions caused by shot firing at the coal face depended on the conditions in which it was used. The safest was to use an 8 ounce charge firmly secured by efficient stemming, which could be of moist clay and coarse sand. It did not seem possible to cause ignition of firedamp by a blown-out shot of a permitted explosive, provided the shot hole was stemmed. The danger of an over-charged shot could be considerably reduced and perhaps removed by the use of a sheathed explosive, in which the explosive was surrounded by a thin layer of sodium bicarbonate. With regard to mine rescue work, a gas mask that protected against carbon monoxide had been devised and could be made available for quick use, even by untrained men.

Sir Alfred Keogh

Sir Alfred Keogh, late director general of the army medical service, has died at the age of 79 years. An Irishman, he graduated from Queen's College, Galway. In 1880 he entered the medical corps of the army and passed through his training course with distinction. His promotion was rapid and he early showed a talent for administration, which afterward made him famous. He earned great distinction in the South African War and in 1902 became deputy director general and in 1905 director general of the army medical service. He was progressive and saw the importance of cooperation with the civil medical profession, especially in times of emergency, and he effectively organized this. When the great war broke out he had retired from the army. His experience and abilities were too great to be dispensed with in that supreme emergency. He was recalled and appointed director general in association with the then director general Sir Arthur Sloggett, who proceeded to France, while Keogh was at the war office at home. In collaboration with the leading consultants he organized hospitals for the wounded soldiers all over the country on a scale that had never before been necessary. He was a man of extraordinarily rapid decision, appearing to know instinctively the proper course, and a great judge of the capacities of men who worked under him. He thus became the greatest medical administrator the army has known.

Compulsory Retirement of Physicians at Age of 65

The lower house of the French congress, the "Chambre des députés," corresponds to the House of Representatives in the United States. At the June 5 session of the Chambre des députés a bill was introduced by Mr. Pomaret which was entitled "Proposition of Law tending to the immediate and steady employment of the youth of France." An examination of the bill reveals that it is not as innocent in its objectives as would appear from the title. It is directed at all members of the liberal professions, including physicians so that diplomas will be rendered null and void whenever the holder has reached the age of 65 years, thus leaving room at the top for the intellectual youths who cannot secure a place even at the bottom of the ladder at the present time in France. Article 3 of the proposed law states that "no one can practice even without pay, after the age of 65 years, as a lawyer, physician, veterinary,

dentist, druggist, architect, surveyor, engineer, accountant, or as an executive in any commercial pursuit." No reference is made to the compulsory retirement at the age of 65 of a politician or those in the diplomatic service. This law should go into effect Jan 1, 1939, it being understood that no pension can be given by the government to compensate those who are forced to retire.

In an editorial in the July 19 *Concours médical*, Noir states that although this proposed law had been spoken of, it seemed so unusual that it appeared to have germinated in the brain of some dreamer and need not be taken seriously. Alas, the bill had been introduced and hence called for vigilance on the part of organized medicine. A year ago the Medical Students' Association of France denounced such a proposition because it felt the injustice of compelling every physician to retire without a pension at 65, when the majority were unable to do so. Nine tenths of the intellectual youth here are sons or daughters of those at whom the law is directed. These young people know that in the majority of cases their parents are obliged to work beyond the age of 65 in order to pay for the education of the children until the latter are self supporting. Unless the parents have inherited money, relatively few, and this is especially true of physicians, have accumulated sufficient funds to live on the rest of their lives at the age of 65. Why those who occupy municipal, state or governmental positions should be exempted is not clear. Many physicians at the age of 65 have reached the acme of their career. Their experience, acquired during many years of study and practical application of their knowledge, is too valuable to the community to be thus thrown into the discard. The proposed law has aroused such antagonism on the part not only of members of the professions enumerated but of the people at large that there is little likelihood of its ever coming to a vote. The younger intellectuals are as opposed to it as those whom it is supposed to push aside to make room for them.

Fifth French Gynecologic Congress

This year's congress of French gynecologists was held at Paris, May 18-21. The honorary president was Professor Alfieri of Milan and the presiding officer was Professor Dartigues of Paris. The subject chosen for discussion was "Sterility in the Female," five papers being read.

Charles Champy of Paris presented the first of these, on "Physiology of Fecundation and Nidation (Fixation) of the Ovum." In the discussion of this paper, Claude Béchère of Paris stated that the integrity of spermatozoa is rarely a cause of sterility and that it was necessary to take into consideration the physiologic role of the male adnexa and the cervix uteri, and the indispensable integrity of the tubal mucosa.

Turpault of Paris called attention to the acidity of the vaginal secretion, to the corpus luteum and the integrity of the endocervical glands.

Jean Seguy of Paris read a paper on "Etiology and Clinical Aspects of Sterility." In the discussion Cova of Turin believed that one was inclined to exaggerate the role assumed by vaginal acidity. Frigidity on the part of the female, which is often associated with ovarian dysfunction, may be responsible for the sterility. For Turpault the function of the liver, the hydrogen ion concentration of the blood, syphilis and intestinal infection play an important part. Gaiffani of Rome considers the existence of tuberculosis during infancy and childhood worthy of serious consideration. Vanverts of Lille maintained that fecundation may take place even when lack of development, displacements (uterine), tumors (uterine and ovarian) and stenoses exist. Many women remain sterile for from five to fifteen years and become pregnant after all hopes have been abandoned wherefore one ought to be guarded as to prognosis. Cotte of Lyons thought that trichomonas infections do not prevent fecun-

dation Mechanical causes, except tubal occlusion, are less important than biologic disturbances, vaginal acidity, altered cervical secretion and changes in the endometrium Labhardt of Basle maintains that the widespread use of contraceptive methods is responsible for endometritis and salpingitis by rendering it more difficult for the ovum to become fixed. He had observed a larger number of extra-uterine pregnancies in his service since contraceptive methods had been employed.

Douay of Paris was of the opinion that male causes play a far less important part than those in the female. After having employed insufflation for determining the patency of the tubes, he has resumed the use of iodized oil.

A third paper on "Medical and Surgical Treatment of Sterility," was read by André Chahier of Lyons. Obliterated tubes can be rendered permeable by insufflation or injection of iodized oil as well as by numerous plastic operations. In sterility of ovarian origin, the treatment of obesity and syphilis are especially indicated. About half of the cases of sterility are curable, but the others often resist all therapy. In the discussion, Cotte of Lyons preferred resection of the presacral nerve for vaginism. Electrocoagulation, according to the method of Filhos, is best for cervicitis and insufflation to render the tubes permeable. In genital hyperexcitability, presacral nerve resection is often combined with partial resection of the ovaries. Mongie of Bordeaux emphasized the necessity of alkalization of the vaginal medium.

The last paper was by Favreau of Lille on "Thermal and Physical Therapeutic Methods." The merits of each of the many thermal stations in France were taken up. High frequency treatment should never be undertaken unless a definite indication existed. Claude Beclère, in the discussion stated that in the majority of cases a cervicitis was accompanied by lesions in the tubes and ovaries, for which reason a diathermy and thermal resort treatment was necessary as a preliminary measure.

BERLIN

(From Our Regular Correspondent)

July 21, 1936

Convention of the German Roentgen Society

This year's convention of the German roentgenologists was held at Wiesbaden in April, the first session was held in conjunction with the internists, the joint meeting representing the final session of the latter group. Kalk, clinician, and Knothe, roentgenologist, submitted their respective papers on "Inflammatory Diseases of the Colon." Kalk said that treatment of a single section of the intestinal tract was most unsatisfactory since the local alterations are often only secondary or, conversely, may be followed by modifications in other organs. He pointed out the efficacy in colitis gravis of alternative anaphylaxis treatment with horse serum and plenty of vitamins. He cautioned against enemas of various kinds. Kalk considers true colica mucosa a neurosis of the secretory nerves.

In the roentgenologic paper, Knothe reviewed the progress of diagnostic methods. Roentgen examination must be competently carried out and each of a number of details must be observed. The roentgenologic picture in the three stages of colitis is sufficiently characteristic. Of particular importance is the determination of the seat and the extent of the pathologic changes. Tuberculosis too is plainly recognizable. Not infrequently there exists a considerable discrepancy between the clinical picture and the roentgenologic appearances.

Alexander of Agra next submitted a paper on the "Diagnosis of Tuberculous Cavities." There are important differences between the round cavities which originate from an early infiltrate in the pulmonary tissue of normal elasticity and the thick walled tertiary cavities and their accompanying symptoms (pleural induration atelectasis). Chaoul of Berlin roentgen-

ologist of the Sauerbruch clinic, demonstrated how by means of tomograms the large bronchi can be given an isolated representation. By separation of the lung roentgenograms into a series that portrays various sectional layers the number, situation, shape and size of tuberculous cavities can be established.

The third paper, "Short Wave Therapy in Internal Medicine," was delivered by Schliephake of Giessen, who discussed the results of research on the distribution of short wave energy in homogeneous and layered mediums. The depth and intensity of the effect is dependent on the wavelength, on the size of the electrodes and on their distance from the body surface. The heat effect from short wave therapy is of trivial and distinctly secondary importance when compared to that of long wave diathermy. Methods for accurate measurement of function and determination of dosage have yet to be evolved. Short wave therapy will be indicated principally in suppurating infections (such as furuncles, carbuncle, abscesses and gynecologic inflammations), rheumatic arthritic disorders and certain circulatory disturbances. For the last named a weak energy is indicated, but for rheumatic joints considerable energy should be used. Numerous astonishing successes in cases of pulmonary abscess have been authenticated. Schliephake holds faulty dosage responsible for lack of success in inflammatory diseases. Too weak energy will be ineffective whereas overdosing will tend to break down the leukocytic bulwark of defense. Knowledge of this sort is essential if short wave therapy is to be successfully carried out. Injudicious application has unfortunately tended to give the method a bad name.

Holthusen of Hamburg submitted a report on "Prevention of Injuries from Roentgen Rays." Among possible harmful after-effects may be mentioned changes in the connective tissues, diminished reproductive function and increased susceptibility to infection in various tissues. Just as it is impossible to estimate the size of the dosage that will destroy a tumor, so it is likewise impossible to delimit the severity of ill effects incurred by the treatment. The critical region in Coutard and radium irradiation lies between two and one-half and six erythema doses, or between 4,500 and 11,000 roentgens. The cause of this latitude of efficacy is to be found in the vast variation of individual sensitivity rather than in the fluctuations of dosage. The total dosage for single areas of tissue, especially with regard to the overlapping of the ray cones, is to be considered a possible source of injury. The circumstances may also be complicated by the combined use of radium and roentgen irradiation. It has been assumed for some time that the musculature and the glandular functions are particularly sensitive. Permanent epilation by roentgen rays is contraindicated as too hazardous. Particular caution should be exercised when persons in the growing stage are subjected to the rays.

Of the technical papers, that of Ziedses des Plantes of Utrecht on "Seroscopy" is particularly worthy of mention. Seroscopy is a roentgenographic procedure which makes it possible, by means of numerous exposures, to examine an endless series of consecutive parallel planes. Thanks to this ingenious device, the object, a skull for example pictures of which are taken from various angles, may be examined according to layers, as it were, just as a preparation may be microscopically studied by turning of the micrometer screw.

In his discussion of "Artificial Radioactivity" von Bothe of Heidelberg considered the risk involved in the use of neutron rays, the formation of gamma radiation of 2,000 kilovolts by the absorption of neutrons in water, and the production of artificial radioactivity by means of artificial transformation of the elements. The neutron rays appear to be extremely powerful from a biologic standpoint rats can be killed by them. This type of irradiation possesses double the hardness of gamma irradiation.

New Regulations for the Insurance Physicians

Several new regulations or decisions have been made recently with regard to the activities of the sick insurance physicians.

The proper authorities have decided that physicians of both sexes by virtue of admission to the insurance practice are to be considered fundamentally as equals. A woman physician must not be superseded by men physicians merely because of her sex. Women insurance holders, on the other hand, cannot demand that medical attention be administered them by women physicians. And if female patients can no longer demand treatment by physicians of their own sex, neither have the male patients any particular right to demand that men physicians attend them.

The insurance practice can now be engaged in only as the physician's principal professional activity. For example, a physician regularly employed outside the insurance practice and the duties of whose post take up most of his time cannot, in addition, serve as an insurance physician.

If a physician should perpetrate an illegal abortion, such an offense should be considered grounds for the revocation of his insurance practice license.

A further decree issued by the director of the Berlin office of the Insurance Physicians' League may be mentioned. It has to do with the question of the consulting room. The members of the insurance societies, it seems, have been increasingly vociferous in their complaints that many physicians maintain separate waiting rooms for private patients and for insurance patients. This arrangement had caused the insured to feel that they were being treated as an underprivileged group and had aroused unrest among them. Discrimination of this sort with regard to patients is contrary to the spirit of National Socialism. Hence the present decree prohibits the maintenance of the separate waiting rooms and, in addition, forbids any separation of consulting hour periods along the same lines.

Jubilee Celebration at Heidelberg

In the last days of June and the first days of July, Heidelberg University celebrated its 550th anniversary with great pomp and circumstance. For some time previously, this jubilee had been discussed in both the German and the foreign press. Twenty countries sent delegations. The United States sent representatives of eighteen universities. Harvard University accepted the invitation and invited the German universities to send their representatives to the Harvard anniversary celebration in September. Heidelberg was richly caparisoned for the reception of its guests, among whom were many of the university alumni from all parts of the world, former American ambassador Shurman was present. The German civil authorities, the army and the National Socialist party were abundantly represented. At a great reception sponsored by the national government, the minister of public instruction, Dr. Goebbels, delivered an address of welcome, in which he said that the endeavor of the entire German people should be to achieve that openmindedness toward life and enjoyment of life for which Heidelberg had always stood. The Heidelberg rector, Professor Groh, a jurist, said that the government took this opportunity to demonstrate the devotion of the new Germany to the task of universal civilization and its sponsorship of high intellectual achievement in all fields of learning, on all fronts of the most peaceful struggle in the world. He declared that at no period of its long history had German scholarship been so liberally aided as in this, our new National Socialist Germany. We feel it as a supreme good fortune, he continued, that the ancient antagonism between politics and learning is no longer an issue. These statements may be compared with the recent statement of the bishop of Durham with reference to the dismissal of faculty members by German universities. He said that "in this evil process Heidelberg stands

in the forefront" (Herbert Dunelm, Bishop of Durham, Auckland Castle, the *Times* [London] Feb. 4, 1936, p. 13). The festival was rendered impressive by the foreign professors in academic garb, who offered their felicitations with the most disparate tokens of friendship. Professor Bohle of South Africa, for example, extended additional greetings from the foreign organization of the National Socialist party and the rector of the University of Canton, China presented a silken banner on which was embroidered a swastika. A different note was sounded by the Swiss jurist Professor Siegwart, who represented the three German-speaking and the three French-speaking universities of Switzerland and whose home city, Freiburg, stands on a linguistic divide. Switzerland, he said, offers an example of the peaceful and untrammelled cooperation of two cultures.

Rust, the national minister of higher education, sought to elucidate the attitude of the National Socialist state toward the universities and toward learning in general. National Socialism has not come to make regulations for higher education or to rob learning of its independent character. Learning is both free and dependent in equal measure, free in its methods of treating reality, dependent on the life of the people. Rust further told how individual branches of learning had been structurally renovated on the basis of the popular *weltanschauung*. Fears have been expressed that National Socialism has placed learning in the degraded position of handmaid to the political power. These politico-academic activities are the expression of a dominant principle of the National Socialist movement. The movement has a mission to restore to the German people a belief in their substance and this work must not be jeopardized by any unworthy tolerance of what is inimical to renascent national self confidence. For this reason those unteachable enemies of Germany's reascent, the Marxist gainsayers of national principle, have been banished from public life. National Socialism contends that a learning devoid of certain preconceptions and ethical foundations would be practically impossible. Rust then emphasized the union of human beings according to community of race and tradition. Learning can be systematic only if based on a living *weltanschauung*. *Weltanschauung* is a fertile ground. The German state of 1933 would never have become great without it. It suffuses life with a new wisdom, but it does not supplant learning. National Socialism has not come to make regulations for learning or to rob learning of its freedom, it has come to provide learning with a new foundation. The academician who talks politics will not be tolerated. True academic autonomy and freedom exist when learning is a spiritual force, at one with the living energies of the people and obedient to the law of truth.

The rector of Heidelberg University, Professor Groh, was promoted by the upper führer of the storm troops to the rank of *sturmführer* (a title which would roughly correspond to that of "colonel" in the regular army). This promotion took place a few days after the close of the jubilee festivities. The façade of the new university building at Heidelberg, on which had previously appeared the inscription "To the Living Spirit" together with a sculptured Pallas Athena, bore instead on the occasion of the jubilee the inscription "To the German Spirit" together with a bronze eagle. Pallas Athena, a confidence-inspiring symbol of truth to Heidelberg students of an earlier day, has been relegated to the rear of the building. The celebration was the occasion for the conferring of forty-three honorary degrees. The following residents of the United States received honorary doctoral degrees from various faculties of Heidelberg University from the Faculty of Philosophy, Prof. Dr. Kirsopp Lake of Harvard University, from the Faculty of Medicine, Prof. Hamilton Laughlin of Cold Spring Harbor, N. Y., eugenist of the Carnegie Institution, from the Faculty

of Jurisprudence, Dr (honoris causa) Ferdinand Thun of Reading, Pa. The Faculty of Jurisprudence bestowed a like degree on William May Garland of Los Angeles for his sponsorship of peaceful competitions between the nations (the Olympic games). The doctor's degree was further conferred on Prof. Reginald Aldworth Daly of Harvard by the Faculty of Natural Science and Mathematics. Henry K. Janssen of Reading, Pa., was similarly honored by the Faculty of Political Science and Economics.

SWITZERLAND

(From Our Regular Correspondent)

June 20, 1936

Humanitarian Enterprises

Switzerland possesses, among other humanitarian enterprises, three great welfare organizations: Pro Juventute, Pro Senectute and Pro Infirmis. The names of these organizations imply their functions. They enjoy the sponsorship of the federal government as well as of the public. This year the Swiss minister of foreign affairs, Federal Councilor Motta, has taken a special interest in the activity of the Pro Infirmis organization, which concerns itself with aid to the indigent infirm. In Switzerland around 200,000 (5 per cent) of the population present some somatic or psychic abnormality. Included in this number are the blind, the deaf, the hard of hearing, the maimed, the decrepit, the feeble-minded and persons presenting any other type of impaired development. By circularizing the public with specially illustrated post cards, the organization was able during the year 1935 to collect the sum of 270,000 francs.

Several recent medical reports on this type of welfare activity are of interest. Professor Schlittler of Basel, for example, announces that the Basel School for the Hard of Hearing, enlarged until it now constitutes an eight-grade school, has in the course of the last twenty years provided a regular schooling for a vast number of children whose hearing is defective and has trained these children to become self-confident and efficient human beings. Similar schools are to be found in Zurich, Bern, Lucerne and other cities. For country school children whose hearing is impaired, a special service has been set up by which their transfer to one of the urban schools for the hard of hearing is effected and it is seen to that these children are suitably lodged while in the city in question. In the last six years more than eighty children from rural communities have been transferred to the urban schools for the hard of hearing and in some cases the Pro Infirmis association has assisted financially in this work.

In Zurich there has existed since 1933 a special kindergarten for children afflicted with deaf-mutism or other defects of hearing. After two years of experimentation, Professor Nager, otologist, of Zurich, reports that these children have made remarkable progress. It was amply demonstrated that instruction of the children should begin precisely at that stage of development which is characterized by an especially lively instinct of imitation and in which normally a child feels an urgent need for conversation and for an understanding of his surroundings. Whereas according to earlier educational methods this period was allowed to remain unutilized in the teaching of the deaf, this period is now filled by preschool instruction and infinitely better results can now be anticipated. At the same time the Zurich kindergarten serves as an observation center wherein the etiology of defective speech development in the children may be traced. In the course of a physician's consulting hours such investigations can obviously yield only approximate data, but at the kindergarten a child easily becomes adjusted to the environment and remains under the constant observation of specialists. The parents too can here become conversant with the educational procedures especially adapted to children with deaf-mutism or seriously impaired hearing.

The children of the kindergarten have become lively and happy in this environment, whereas previously many of them had been excluded from normal contacts and play within their own family circles and been forced to remain apart. In Geneva a similar kindergarten has been in existence for several years. According to investigations undertaken there, 3 years is likewise considered the optimal age at which a child should be admitted to the institution.

The Migration of Virus Along Peripheral Nerves

A recent discussion of the migration of virus along the peripheral nerves by Robert Doerr, professor of hygiene at Basel, contained some observations that are of fundamental importance. It is widely assumed that certain types of virus travel by their centripetal migration in the axis cylinders while tetanus toxin on the other hand may be passively assisted by fluid currents in the perineural spaces of the central nervous system. A critical analysis of the literature leads one to conclude that the two alternatives ("active growth or passive transport" and "axis cylinder or perineural lymph spaces") do not exhaust all the possibilities. Doerr describes observations that seem to substantiate this hypothesis. The point of departure is the establishment of the velocity of migration of the virus of herpes in the trigeminal tract leading from the rabbit's cornea to the brain by estimating the minimal interval of time at which the virus is demonstrable in two successive points of the tract (gasserian ganglion and sensory trigeminal nucleus on the inoculated side). There resulted surprisingly few values that were not in accord with the concept of an ordinary progress of the infectious process, which moreover spread centripetally with absolute constancy and in even tempo. The establishment of a concentration of virus in the passage as well as the fact that the migratory process remains completely latent functionally and frequently exhibits no histologic changes speaks further against an "ascending infection." Moreover, Magrassi has been able to show that that strain of herpes which develops no encephalitis filters through the trigeminal tract, reaches the brain and quickly produces a cerebral immunity. Implanted directly into the brain, the "nonencephalitic pathogenic" strains develop, however, a maximal capability of infection whence the conclusion follows that the "scheneninfektion" (track infection) must be directed by a special mechanism. This may be satisfactorily explained either by an ordinary infection of the nerves or by a purely passive transport of virus. The phenomenon of "opposing manners of infection" observed by Magrassi allows itself to be evaluated in the same sense. When rabbits were subjected first to peripheral and then, after an interval, to intracerebral inoculations with encephalitogenic strains the "scheneninfektion" and the direct cerebral infection canceled each other. The animals thus survived both interventions without exhibiting any symptoms, whereas any single one of the two infections inevitably was fatal. The results of experiments with intravascular injections of the virus of herpes make it necessary to alter the prevalent concept of more fixed and more highly differentiated special neurotropisms. According to the vessel selected, either a primary myelitis or a primary encephalitis can be produced. The nerve conduction theory of tetanus toxin (H. H. Meyer) can now be supported by a new argument (the dynamic activation of the toxically induced local tetanus). Since the detection of toxin in the ischiatic nervous tract succeeds only when the circumstances offer conclusive proof of the positive condition a passive transport by currents in the perineural lymph spaces must be concluded. According to H. H. Meyer's theory it is necessary to bring into consideration other toxins (diphtheria, botulinus, Shiga) in order to answer the question of what properties an agent must possess in order to be absorbed and conducted by the nerves.

Causes of Death Among the Viennese

The Federal Bureau of Statistics has at last made public complete statistics on the causes of the deaths that occurred in Vienna during 1933 and 1934. Diseases of the heart and vascular system occupy first place (male patients 17.2 per cent, female patients 20.5 per cent), the next ranking cause was malignant tumors (male patients 12.3 per cent, female 14.5 per cent). Third place is occupied for males by tuberculosis (9.6 per cent), for females by pneumonia (8.3 per cent), conversely, in fourth place is pneumonia with 8.3 per cent among males and tuberculosis with 7.9 per cent among females. The incidence of fatalities from different causes and the relative endangerment of the populace by various diseases have been computed per hundred thousand of population. According to this report virtually all diseases underwent a decrease. The death rate from cardiac and vascular disorders has sunk from 234.4 to 231.3 per hundred thousand of population. On the same basis the mortality from tuberculosis has declined among males from 141.5 to 128.5, among females from 100.7 to 93.4. The decline in the number of suicides, from 59.3 to 53.9 per hundred thousand among males and from 25.2 to 24.3 among females, is gratifying. Only fatalities from malignant tumors showed an increase among males from 157.3 to 164.1 per hundred thousand. The following detailed data can be quoted. The 24,808 fatalities recorded in 1933 were apportioned according to cause as follows: infectious diseases 3,658 (including 2,337 deaths from tuberculosis of the respiratory tract), cancer 3,998, diabetes 402, diseases of the blood 248, diseases of the nerves and of the organs of sense 2,485, diseases of the circulation 5,661 (of which 4,376 were from organic heart disease), diseases of the organs of respiration 2,724 (of which 1,971 were from pneumonia and costal pleurisy), diseases of the digestive system 1,504, diseases of the genito-urinary system 746, deaths occasioned by pregnancy and the puerperium 113. In addition, 391 children died in the first year of life and 686 persons succumbed to the infirmities of age. There were also a number of violent deaths, 1,235 of which were suicides.

Has the Patient a Right to His Case Record?

An interesting decision recently handed down by the Supreme Court of Judicature marks another pronouncement on the physician-patient relationship. A male patient had been admitted to a private sanatorium for treatment for an intoxication caused by a hypnotic. The treatment had been successful but the patient decided to institute a personal injury suit against the manufacturer of the drug in question. To strengthen his allegations, he wished to make use of the clinical history of his illness and requested the attending physician to furnish him this record. When the doctor and the sanatorium denied his request the man brought legal action against both, demanding the delivery of the record. The defense contended that the histories of patients are in the nature of an attending physician's private notations, intended solely for his personal use, that such records should never be accessible to a patient and that, furthermore, if the plaintiff wished to sue the pharmaceutical concern he could have the members of the sanatorium staff subpoenaed as medical witnesses. But the legal duty of professional secrecy the defense concluded, prohibits the surrender of a case record by a physician.

The medical experts who testified in this case were of the opinion that case records were to be regarded as a physician's personal property and that under no circumstances should a patient be permitted access to them and, further, that a universally recognized principle of professional ethics forbids the physician to furnish a patient full information on the latter's

physical condition if such intelligence might upset the patient's mental equilibrium. It must therefore remain within the discretion of the physician whether he wishes to supply a patient with the case history.

On the basis of this expert opinion the Supreme Court dismissed the suit. The decision specifically stated that a patient has no right to demand access to the record of his case if the physician considers the divulgence of the data therein contained contraindicated for psychological reasons. There exists accordingly no legal avenue by which the plaintiff may become acquainted with the etiology and clinical course of his malady. In case action is brought against a pharmaceutical manufacturer, the court itself may impound medical records for its own guidance in the formulation of a judgment, but the relinquishment of a medical record cannot be legally claimed by private persons, and the plaintiffs in the present or in any similar case are to be regarded as such.

The New Electropathologic Institute

The Electropathologic Museum, previously housed at the Institute of Forensic Medicine, has been moved to new quarters in the former Garrison Hospital. The institute was founded thirty-five years ago by Prof. Stephan Jellinek and still remains under his direction. As it is the only establishment of the kind in the entire world, engineers and physicians of every nationality throng there to study problems in the field of electropathology. The museum contains many exhibits of unusual and unique interest, for example, a valuable historical collection on electricity. Among the activities of the institute may be mentioned recent research on prevention of electrical accidents, on improvements in industrial safety and on kindred problems.

Among other exhibits lodged in two great halls are a special collection of material illustrative of the effects of lightning, sections on protection against electricity, the application of electricity to military science, electromedical apparatus and electropathology in everyday life. In addition there are the laboratories and a lecture hall. The institute has become particularly important in recent years for its work on those forensic problems which have been created by the daily use of electrical appliances. In the school conducted by Professor Jellinek at this institute a number of the most eminent research scholars in the field have received their training.

RIO DE JANEIRO

(From Our Regular Correspondent)

July 15, 1936

Immunotransfusion

Dr. Cruz Lima, director of the blood transfusion center in Rio de Janeiro, in a recent lecture reviewed the work of Wright and his school on immunotransfusion. The speaker differentiates three types of immunotransfusion: true immunotransfusion (conferring immunity), prophylactic transfusion (conferring protection) and allergic transfusion (transmitting allergy). The speaker reported the results of the three different types of transfusion in a group of eighty patients suffering from infections. Immunotransfusion was given to fifty-eight, simple transfusion to fourteen and both types of transfusion to eight. Recovery took place in twenty-seven patients out of the group of fifty-eight who were treated by immunotransfusion, the condition did not change in one and there were thirty deaths (51 per cent). Recovery took place in two patients in a group of fourteen who were treated by simple transfusion, the condition did not change in one and eleven patients died (78 per cent). In the group of eight patients who received both types of transfusion, four recovered and four died (50 per cent). The results point to the advantage of using immunotransfusion in infections. A comparison of the effects of immunotransfusion in different infections gives the

following results In twenty-five cases of streptococcic infections complicated by septicemia there were nine recoveries and sixteen deaths, in twelve cases of staphylococcic infections there were six recoveries and six deaths, in sixteen cases of infections of unknown origin, especially from pyogenic bacteria, there were eleven recoveries and five deaths In all cases of myocardial involvement there was a fatal outcome, which shows the importance of early suppression of the focus of infection In seven cases of typhoid treated by immunotransfusion there were two recoveries and five deaths Transfusion in these cases was performed in desperately grave cases In the group of thirty-two patients who died after having received immunotransfusion, ten patients (29 per cent) were given transfusion in the last twenty-four hours before death It is advisable to perform immunotransfusion early in the development of infections, in sufficient dose (from 400 to 500 cc) and repeat it at least every forty-eight hours By the speaker's observations it seems that immunotransfusion is contraindicated in cases of latent tuberculosis, which seems to enter on activity by immunotransfusion

Congress of Orthopedics

The First Brazilian Congress of Orthopedics and Traumatology met July 1-3, in São Paulo There was a large attendance of Brazilian orthopedic surgeons Those who met previously at the reunion of the Orthopedic Regional Society of Rio de Janeiro were also present Prof Vittorio Putti, guest of honor of the congress and of the government, delivered his first lecture at the inaugural session, on orthopedic surgery in contemporaneous medicine Dr Barros Lima, professor of the Faculty of Medicine of Recife and president of the Orthopedic Society of the northern region of Brazil, spoke on tuberculosis of the bones Dr Resende Puech described his technic of anterior tibiotarsal arthrodesis, with bone implantation, in treatment of paralytic calcaneus foot

Maternity Hospital for Tuberculous Women

Festivities were held by the Associação de Socorros aos Tuberculosos on occasion of the opening of the Plácido Barbosa pavilion for the care of pregnant tuberculous women The pavilion is part of a maternity hospital which is in construction and which is in connection with the São Sebastião Hospital The institution covers a need in the care of tuberculous women that previously had not been given the attention it deserves

Marriages

ARTHUR ALLAN HUMPHREY, Battle Creek Mich to Miss Frances Adelaide Whalen of Fort Wayne, Ind., September 2

CHARLES SALTZMAN, Loch Sheldrake, N Y to Miss Frances Selma Heller of Brookline, Mass recently

ARTHUR STRAUSS, Long Branch N J to Miss Winifred Armstrong of Rumson, in New York, July 30

REYNOLD ERSKINE CHURCH, New York to Miss Mary Eltinge Ostrander of White Plains June 25

ERLAND MYLES STANDISH Wethersfield, Conn, to Dr HILDA C CROSBY of Hartford, June 25

ROBERT MAYES SEAWRIGHT to Miss Margaret Alsobrook, both of Bolton Miss, July 24

LOUIS BLACK LEE, Tiltonville, Ohio, to Miss Blanche Allen of Washington, D C., July 4

DONALD MARION CALDWELL, Irvington, N J to Miss Mabel Wood of New York, July 6

CLYDE HOBSON FOSHEE, Madisonville, Ky to Miss Isabel Board of Louisville June 6

HARVEY M FRY, Rush Pa., to Miss Ruth H Payne of Montrose, July 24

ABRAHAM H BARRIS to Miss Sadie Furman both of New York, July 4

DAVID WILLIAM FRY to Miss Wilma Buehler, both of Peoria Ill., June 20

Deaths

Clarence King ☉ Cincinnati Medical College of Ohio, Cincinnati, 1901, member of the American Academy of Ophthalmology and Oto-Laryngology and the American Ophthalmological Society, fellow of the American College of Surgeons, professor of ophthalmology, University of Cincinnati College of Medicine, served during the World War, director of the ophthalmic service, Children's Hospital, attending surgeon to the Cincinnati General Hospital and director of the outdoor clinic, ophthalmologist to the Christ Hospital, at various times served on the staffs of the Ophthalmic Hospital Good Samaritan Hospital and Deaconess Hospital was active in the establishment of the laboratory of ophthalmic pathology at the Christian R Holmes Hospital aged 57, died August 15, while swimming at Grape Bay, Hamilton, Bermuda.

Frank Richard Oastler ☉ New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York 1894, professor of clinical gynecology at his alma mater, attending gynecologist to the Lenox Hill Hospital, consulting gynecologist and obstetrician to the Lincoln Hospital, consulting surgeon to St Luke's Home for Aged Women consulting gynecologist to St. Luke's Hospital Newburgh, fellow of the American College of Surgeons, aged 65, died, August 2, in Glacier National Park, Mont., of coronary occlusion

William McDonald Jr, ☉ Marion, Mass Columbia University College of Physicians and Surgeons, New York 1899, at one time clinical instructor in neurology at Yale University School of Medicine, New Haven, Conn, served during the World War, at various times on the staffs of the Butler Hospital and Rhode Island hospitals, Providence, R I, Sayles Memorial Hospital, Pawtucket, R. I., and the New Haven (Conn) Hospital, aged 63, died, August 1

Ira Dean Loree ☉ Ann Arbor, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901, member of the American Urological Association fellow of the American College of Surgeons, assistant in surgery at his alma mater from 1901 to 1907 and associate professor of surgery from 1907 to 1920, for many years on the staff of St Joseph's Mercy Hospital, aged 67, died suddenly, August 10, at his home in Barton Hills

Edward John Riley ☉ New York, Albany (N Y) Medical College, 1908, assistant clinical professor of medicine, New York University College of Medicine, served during the World War, for many years police surgeon aged 51, consulting physician to St Ann's Maternity and St Elizabeth's hospitals, New York, and St Joseph's Hospital, Yonkers, N Y attending physician to St. Vincent's Hospital, where he died, August 3

Robert Kendig Rewalt ☉ Williamsport Pa University of Pennsylvania Department of Medicine, Philadelphia 1908, past president of the Lycoming County Medical Society, member of the American Academy of Pediatrics served during the World War, for many years chief of the pediatric service and member of the board of managers of the Williamsport Hospital, aged 49, died, July 27, of cerebral hemorrhage.

George Joseph Hauer, New Orleans Tulane University of Louisiana Medical Department, New Orleans, 1912 member of the Louisiana State Medical Society member of the Southeastern Surgical Congress, fellow of the American College of Surgeons served during the World War, on the staff of the Touro Infirmary and French Hospital aged 46, died suddenly June 2 of chronic nephritis and myocarditis

Alfred Benedictus T Lippert, Sidney, Ohio Miami Medical College, Cincinnati 1896 member of the Ohio State Medical Association for many years a medical missionary in West Africa, formerly director of the child hygiene division of the state department of health at Columbus health commissioner of Shelby County aged 61, died July 1 in Rochester Minn. of carcinoma of the stomach

Aloysius James Larkin ☉ Chicago Rush Medical College Chicago 1916, associate in radiology at Northwestern University Medical School aged 47, author of a book called Radium in General Practice at various times on the staffs of St Francis Hospital Evanston Ill University Cook County Evangelical, Edgewater and Wesley Memorial hospitals where he died August 20 of coronary occlusion

Thomas Scott Ragland, ☉ Gilmer Texas, Vanderbilt University School of Medicine, Nashville Tenn. 1894 past president and secretary of the Upshur County Medical Society formerly county health officer for many years bank president

medical superintendent of the Ragland Clinic-Hospital, aged 64, died, June 19, as the result of injuries received in an automobile accident

John Milton Walker * Kansas City Mo., Tulane University of Louisiana School of Medicine, New Orleans, 1913, member of the Associated Anesthetists of the United States and Canada, served during the World War, on the staffs of St. Joseph Hospital and the Trinity Lutheran Hospital aged 45, died, June 11, of lobar pneumonia

O Grant Harrington * Niagara Falls N. Y., University of Buffalo School of Medicine 1895, past president of the Niagara Falls Academy of Medicine at one time coroner of Lewis County N. Y., member of the staffs of the Mount St. Mary's and Memorial hospitals, aged 69, died, June 1 in Lowville, of coronary thrombosis

William Charles Vickers, Abbeville Ala., Tulane University of Louisiana Medical Department New Orleans 1908 member of the Medical Association of the State of Alabama past president of the Henry County Medical Society veteran of the Spanish-American War, formerly county physician aged 53, died, June 7

Charles Benjamin Sprague, Troy N. Y., University of Vermont College of Medicine, Burlington 1898 member of the Medical Society of the State of New York, formerly a county coroner aged 64 for many years on the staff of the Leonard Hospital, where he died, June 7, of chronic nephritis and myocarditis

Thomas Verner Moore * San Jose Calif., John A. Creighton Medical College, Omaha 1911, fellow of the American College of Surgeons, served during the World War on the surgical staff of the San Jose Hospital and O'Connor Sanitarium, aged 52, died, June 6, of adenocarcinoma of the stomach

Charles Sumner Hamilton * Columbus, Ohio, Columbus Medical College, 1887, emeritus professor of surgery, Ohio State University College of Medicine served during the World War aged 72, on the staffs of the Children's Hospital and Mount Carmel Hospital where he died, June 26 of heart disease.

William Louis Hartman, Highland Park Mich., Hahnemann Medical College and Hospital, Chicago 1887, fellow of the American College of Surgeons, medical director of the New York Central Lines aged 68 on the staff of the Grace Hospital, Detroit, where he died, June 1 of cardio-renal disease.

George Willis Robinson * New Orleans, Tulane University of Louisiana School of Medicine New Orleans 1932 assistant clinical professor of ophthalmology at the Louisiana State University Medical Center on the staff of the Charity Hospital, aged 28, was drowned, July 19, at Grand Isle La

Frank Bryant Horner, Campbellsburg Ind., University of Louisville (Ky.) Medical Department 1913, member of the Indiana State Medical Association formerly county coroner aged 51, died, June 6 in the Pennington General Hospital, London, Ky., of injuries received in an automobile accident

James Henry Thorpe * Owensboro Ky., Barnes Medical College, St. Louis, 1899 past president of the Daviess County Medical Society, member of the staff of the Owensboro City Hospital, consultant surgeon to the Mary Kendall Home, aged 60, died, June 6, of carcinoma of the stomach

Lucien Luttrell Miner * Los Angeles, Columbia University College of Physicians and Surgeons, New York 1904 fellow of the American College of Surgeons at various times on the staffs of the Hospital of the Good Samaritan and Hollywood Hospital, aged 57 died, June 5 of heart disease

Bernays Kennedy, Indianapolis, Medical College of Indiana, Indianapolis, 1893, served during the World War, at one time associate professor of gynecology Indiana University School of Medicine, aged 63, died, June 29 in Duluth Minn. of diabetes mellitus and coronary sclerosis

Vernon Champney Stewart * Woburn Mass., Columbia University College of Physicians and Surgeons New York 1904, formerly medical examiner for the Woburn district, on the staff of the Charles Choate Memorial Hospital, aged 56 died June 20, in New Ipswich, N. H.

Daniel W. McMillan, Pensacola Fla., Tulane University of Louisiana School of Medicine New Orleans 1893 member of the Florida Medical Association served during the World War aged 67 died August 4 in a local hospital following an operation for appendicitis

William Wadsworth Stirlen, Muscatine Iowa, Keokuk Medical College College of Physicians and Surgeons, 1905

member of the Iowa State Medical Society aged 55, on the staff of the Benjamin Hershey Memorial Hospital, where he died, June 9, of septic endocarditis

Thomas James Glenn, Cincinnati, Medical College of Ohio, Cincinnati, 1908, member of the Ohio State Medical Association aged 52, on the staff of the Good Samaritan Hospital, where he died June 27, of septicemia and subacute endocarditis

Abram Harvey Van Riper, Nutley N. J., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1878 at one time postmaster, aged 82 died June 26, in St. Mary's Hospital, Passaic, of pulmonary embolism

George Eugene Ober * Bridgeport, Conn., University of Vermont College of Medicine Burlington, 1890, past president of the board of health aged 73 died June 11, in a local hospital of perforated duodenal ulcer and general peritonitis

Elmer Lee Ruble * Kansas City, Mo., University Medical College of Kansas City, 1905 served during the World War member of the staffs of the Wesley Hospital and St. Mary's Hospital, aged 55, died, June 1, of heart disease

Austin James Kemp, Miami Fla., University of Nashville (Tenn.) Medical Department 1903, member of the Florida Medical Association, served during the World War, aged 56, was found dead, June 8, of heart disease

Justin Gideon Hayes, Williamsburg Mass., University of the City of New York Medical Department, 1881, member of the Massachusetts Medical Society aged 86, died, June 18, in the Cooley Dickinson Hospital, Northampton

Omer Hamilton McDonald, Remus, Mich., Starling Medical College, Columbus, 1903, member of the Michigan State Medical Society, aged 66, died, June 12, in the Kelsey Hospital, Lakeview, of chronic myocarditis

George Gove Kelly, Hingham, Mass., Hahnemann Medical College and Hospital, Chicago, 1908, at one time on the staff of the Boston State Hospital, aged 62 died, June 27 in the Springfield (Mass.) Hospital

George B. C. Elliott, Millvale Pa., Western Reserve University Medical Department Cleveland, 1889, member of the Medical Society of the State of Pennsylvania, aged 72 died, June 22, of cerebral hemorrhage.

Humphrey H. Bate, Castalian Springs, Tenn., University of Nashville Medical Department, 1897, member of the Tennessee State Medical Association veteran of the Spanish-American War, aged 61, died June 12

Dudley Leavitt Stokes * Rochester, N. H., Dartmouth Medical School, Hanover, 1889 formerly city and county physician, at one time on the staff of the Frisbie Memorial Hospital, aged 70, died, June 25

Victor Frank Carey, Downsville, La., Tulane University of Louisiana Medical Department, New Orleans, 1910 member of the Louisiana State Medical Society, aged 50, died, June 24, in a hospital at Monroe.

Nathaniel Frutkow * Chicago, University of Kansas School of Medicine Kansas City Kan. 1914 aged 46 member of the staff of the Henrotin Hospital, where he died, July 20, of streptococcal meningitis

Hugh Edward Prather * Hickman, Ky., University of Louisville Medical Department, 1901 served during the World War, formerly county health officer, aged 58, died, June 1, of a ruptured gallbladder

William Eugene Russell, Hico Texas, Vanderbilt University School of Medicine, Nashville, Tenn. 1900, aged 71 died June 11, in a hospital at Waco, following an operation for intestinal obstruction

Matthew E. McManes, Piqua Ohio, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1898, aged 60 died suddenly, June 6, of cerebral hemorrhage.

Abel J. Sands * Choctaw, Okla., College of Physicians and Surgeons, Keokuk, Iowa 1889, veteran of the Spanish American War formerly member of the state legislature aged 69 died, June 16

Hugo Louis Heitefuss * Wilmington, Del., Long Island College Hospital, Brooklyn, 1928, on the staffs of St. Francis and Delaware hospitals, aged 32, died suddenly June 29 of coronary thrombosis

Robert F. Price, Terre Haute, Ind., Medical College of Ohio Cincinnati, 1886 member of the Indiana State Medical Association aged 76 died June 27, of coronary embolism and chronic myocarditis

Gilbert Miller ☉ New York, University and Bellevue Hospital Medical College, 1908, on the staffs of the *Lyng-in* Hospital and the Jewish Memorial Hospital, aged 49 died suddenly, June 3

Albert Gustaf Lundgren, Mattapan, Mass., Boston University School of Medicine 1933, served during the World War, aged 44 died, June 28, in the Barnstable County Sanatorium, Pocasset

Washington Pierce Glover, Atlanta, Ga., Bellevue Hospital Medical College, New York, 1876, Civil War veteran, aged 83 died, June 20, of acute dilatation of the heart and arteriosclerosis

Kathalyn Voorhis, Worcester, Mass., Tufts College Medical School, Boston 1916, member of the Massachusetts Medical Society, aged 50, died, June 19, in the Harvard Private Hospital

Jacob Kendell, Covington, Ohio, Miami Medical College, Cincinnati, 1869, formerly bank president, for many years member of the school board and city council, aged 89, died June 8

Edmond Dawson Standly ☉ Brookfield Mo., University Medical College of Kansas City, 1897, served during the World War, aged 64, died, June 16, of carcinoma of the bladder

J H Linzy, Comanche, Okla. (registered in Oklahoma by the state board of health under the Act of 1908), member of the Oklahoma State Medical Association, aged 76 died in June

Bernard Charles Kelly, Carroll Iowa, Hahnemann Medical College and Hospital, Chicago, 1887, aged 75, on the staff of St. Anthony Hospital, where he died, June 11 of carcinoma

John Franklin Cave, Kansas City Mo., Western Eclectic College of Medicine and Surgery, Kansas City, 1908, aged 63 died June 21, of coronary embolism and chronic myocarditis

William Bright March, San Jose, Calif., Eclectic Medical Institute, Cincinnati 1884, member of the California Medical Association, aged 76 died, June 23, of cerebral hemorrhage

Frank John, McKeesport, Pa., Eclectic Medical Institute Cincinnati 1882, Baltimore Medical College, 1894, aged 87 died June 13, of arteriosclerosis and chronic myocarditis

Ernest L Griffith ☉ Clifton Forge Va., University of Maryland School of Medicine, Baltimore, 1907, served during the World War, aged 51 died suddenly, June 21

William D Lewis, Beckley, W Va., University of Louisville (Ky.) Medical Department, 1912, served during the World War, aged 49 died June 10, in a local hospital

Jacob La Porte ☉ Chicago, Illinois Medical College Chicago, 1907, aged 55, died August 22 in the Edgewater Hospital, of cerebral hemorrhage and hypertension

Elmer E Mosher, Greenwich, N Y., Hahnemann Medical College and Hospital of Philadelphia, 1885, aged 75, died June 24, of diabetes mellitus and acute nephritis

Spencer P McNairn, Burleson, Texas, Memphis (Tenn.) Hospital Medical College, 1899, member of the State Medical Association of Texas, aged 66, died June 17

Thomas Pollard Darracott, Tunstall, Va., Medical College of Virginia, Richmond 1885, member of the Medical Society of Virginia, aged 77, died, June 26

Charles Melville Harrington, Chicago, Chicago Homeopathic Medical College, 1899, aged 64, died August 17, of chronic nephritis and cerebral hemorrhage

Orrin Philander Joslin, Carthage N Y., University and Bellevue Hospital Medical College, New York, 1899, aged 59, died June 11, of cerebral hemorrhage

Arthur M Ruhl ☉ Edmond, Okla., Kansas City Homeopathic Medical College 1900, aged 60 died June 27 in a hospital at Oklahoma City, of pneumonia

Charles Newton Gartin ☉ Chicago, Bennett Medical College, Chicago 1912, aged 46, was drowned while swimming in Lake Michigan at Gary, Ind. June 14

Daniel Lawrence Moore, Nahunta Ga., Atlanta Medical College 1894, member of the Medical Association of Georgia, aged 62 died June 23 of angina pectoris

Granville Storey Ramsay, Collins Miss., Emory University School of Medicine Atlanta Ga. 1923, aged 37 died May 27 in the Methodist Hospital Hattiesburg

Samuel Ekenborg Latta, Stockton Calif., Rush Medical College, Chicago 1884, member of the California Medical Association, aged 74 died June 13

Moses I DeVorkin, Los Angeles (licensed in Missouri in 1891), formerly a practitioner in St. Louis, aged 73 died suddenly, June 6, of heart disease

Robert Michael Hillary, Aurora, Ont., Canada, Trinity Medical College, Toronto, 1890, aged 73, died June 1 in the Christie Street Hospital, Toronto

John Ross Beiter ☉ Canton Ohio, Western Reserve University Medical Department, Cleveland, 1907, aged 56, died, June 30, of coronary thrombosis

Rollin Jones Goss, Wilder, Vt., Baltimore Medical College, 1896, aged 65 died, June 26, of coronary thrombosis, arteriosclerosis and hypertension

John B Lichtenwallner, Omaha, University of Pennsylvania Department of Medicine Philadelphia, 1882, aged 76 died, June 25 of chronic myocarditis

Frank A Stahl ☉ Chicago, Rush Medical College Chicago 1887, at one time instructor in obstetrics at his alma mater, aged 73, died, June 10

Thomas D Miller, Aurora, Mo., Missouri Medical College, St. Louis 1898, aged 69, died June 8 in St. Louis of carcinoma of the stomach

Charles McConnell, Hogsburg N Y., University of the City of New York Medical Department, 1881, died June 15, of coronary thrombosis

Horace B Dean, Horseheads, N Y., Hering Medical College, Chicago, 1910, aged 63, died, June 4, of cerebral hemorrhage and pneumonia

Joseph Allen Graham, Long Beach, Calif., Queen's University Faculty of Medicine, Kingston, Ont., Canada 1904, aged 58, died, June 18

Franklin Eliada Way, Talmo Kan., Kansas City (Mo.) Medical College, 1895, aged 68, died, June 18 of arteriosclerosis and myocarditis

Louis Montrose Coon, Denison Iowa, St. Louis College of Physicians and Surgeons, 1898, aged 70, died, June 13, of myocarditis

David Ellis Miller ☉ Monett Mo., Kentucky School of Medicine, Louisville, 1897, aged 69 died, June 23, of cerebral hemorrhage

William M Cawhern, Atlanta, Ga., Atlanta College of Physicians and Surgeons, 1899, aged 69, died, June 24 of erysipelas

Edwin E Lamb, Ellwood City, Pa., Cleveland University of Medicine and Surgery, 1897, aged 66, hanged himself, June 11

"POOLED CONVALESCENT HUMAN SERUM IN POLIOMYELITIS"

To the Editor —It is the duty of every practicing physician to offer hope and comfort to the family of a patient who is ill with poliomyelitis. Your recent editorial (*THE JOURNAL*, August 8, p. 432) offers such consolation particularly with respect to serotherapy. Yet certain evidence obtained from recent epidemics makes the value of convalescent serum as a therapeutic measure in the acute stage of poliomyelitis extremely doubtful. One has only to recall that until recently serum was employed in the paralytic stage of poliomyelitis with apparent efficacy. More careful workers later were led to the opinion that certain indicators of the value of serum in cases of paralysis were unreliable, for paralyzed patients were usually past the acute stage of their disease. The drop in temperature or the apparent arrest of paralysis following the administration of serum was often seen also in patients who had received no serum.

The same uncertainty holds true in appraising serum used in the preparalytic, or what is termed the meningitic, stage of the disease. During the 1931 epidemic (Fischer A. E. Human Convalescent Serum in the Treatment of Preparalytic Poliomyelitis, *Am J Dis Child* 48:481 [Sept.] 1934), although 477 cases were treated and over a hundred control cases were studied, no decision could be reached. It was definitely shown, however, that in many cases diagnosed in the meningitic stage and untreated, paralysis never occurred. Had the same patients received a serum one would have been led to the conclusion that recovery was due to the treatment.

Another opportunity to study the question again presented itself last summer when an epidemic occurred in New York City. Of the 685 patients with poliomyelitis admitted to the Willard Parker Hospital, 282 had no paralysis on admission. Only fifty-seven of these 282, or 20 per cent, ever developed any paralysis and none of these died. There were therefore, four chances in five that paralysis would not develop in a case seen in the 'preparalytic' or meningitic phase. No serums or transfusions of any kind were employed. It was not possible to determine how many of the paralyzed patients had a 'preparalytic' phase. Some of them no doubt did. All the deaths (eighteen) that occurred were of patients who were already paralyzed on admission to the hospital, in other words, those in whom the virus nerve cell union had already taken place.

In the light of the experience of the 1935 epidemic then, it can be said that if the diagnosis of the disease was made in the meningitic stage the case offered a good prognosis. A careful analysis of the available data in other recent outbreaks likewise bears out the same contention. In the 1934 California epidemic there were large numbers of preparalytic cases and consequently a low mortality (*Am J Pub Health* 24:1204 [Dec.] 1934). In Denmark in 1934 less than 20 per cent of the patients developed paralysis (Jensen, C. The 1934 Epidemic of Poliomyelitis in Denmark. Preliminary Report of the Epidemiological and Clinical Features and Convalescent Serum Therapy, *Proc Roy Soc Med* 28:1107 [June] 1935). The two epidemics were both mild, as evidenced by the low mortality. They were comparable in other respects (age distribution, communicability, and so on).

It may be argued that the foregoing statements hold only for convalescent serums and not for so-called normal pooled adult serums which are said often to exceed convalescent serums in their ability to neutralize the virus of poliomyelitis. Unfortunately, the method used to test the virucidal substance in serum is a very crude one. Because of the many variables in the performance of the monkey serum neutralization test,

one must accept with caution statements that certain serums are more potent than others. Indeed, one cannot even be certain that real "antibody," which may be of help in the human disease, is present in the circulating blood for since serums from poliomyelitis convalescents often do not possess neutralizing power, may it not be that one is dealing with tissue immunity in that disease rather than humoral immunity? There is no evidence which justifies placing any therapeutic value on any serum in the treatment of poliomyelitis at the present time.

ALFRED E. FISCHER, M.D., New York

MEASURING PRESSURE OF BILE DUCTS

To the Editor —I was very much interested in the communication from Dr. Harry Koster and Dr. Arthur Shapiro in the August 1 issue of *THE JOURNAL* relative to the method they used in studying the pressure within the common bile duct. Our failure to read their article is attributable to the fact that it was hidden in their paper, which was entitled "On the Rate of Secretion of Bile."

In discussing with physicist Charles Sheard the question of intraductal pressure, I obtained permission to quote him as follows: "The intraductal pressure, as has been pointed out by Koster, Shapiro and Lerner, should include, in addition to the reading of the manometer attached to the T-tube, the equivalent vertical height from the point of entrance of the tube in the abdomen to the end of the common duct. In the report of the investigations on pressure in the common bile duct by McGowan, Butsch and Walters, it is definitely stated that all measurements of pressure were made from the abdominal wall. The data which they present are concerned with changes in pressures and, by reason of the omission of the equivalent pressure from the abdominal wall to the end of the duct, are not to be regarded as measurements of total pressure. Throughout the paper emphasis is laid on rise (or change) of pressure subsequent to the administration of certain drugs."

Dr. Sheard's statement should clarify the situation.

WALTER WALTERS, M.D., Rochester, Minn.

TREATMENT OF ACID BURNS OF THE EYE

To the Editor —In *THE JOURNAL*, August 8, appeared a communication from Dr. W. D. Hubbard of Flint, Mich. He treats all acid burns with large quantities of water. In most instances I concur with this treatment as the first measure. However, there is one exception to this first treatment in the case of concentrated sulfuric acid. This acid should be wiped off first, if possible, and then large quantities of water used. Concentrated sulfuric acid does not burn much until water is applied.

Caustics or alkalis burn the cornea of the eye, hair and horny tissues on contact while the conjunctiva burns more slowly. The burning and penetrating action of the caustic or alkali leaves a layer of coagulated albumin above it. In experiments on guinea-pigs I have found that water does not penetrate this coagulated albumin and hence does not neutralize nor dilute the caustic or alkali.

My work has shown that ammonium chloride in a 1 or 2 per cent solution neutralizes the caustic or alkali and does not produce heat in its chemical action because both are salts.

The ammonium chloride solution also penetrates the coagulated albumin and neutralizes the caustic or alkali within the tissues faster than anything else that I have tried.

Experimental work has shown also that the 1 or 2 per cent solution was as strong as I dared use in the eye, for stronger solutions produced exfoliation of the epithelium of the cornea. I flush the eye with a 1 per cent solution of ammonium chloride every fifteen minutes for two hours, then every half hour for three hours and then every hour for twelve hours.

Since using ammonium chloride for caustic or alkali burns I have had few blind eyes. Under this care they clear up faster.

Of course, if this treatment is not started soon enough a great deal of destruction will have taken place, and after the neutralization the resulting ulcer must be treated in the usual way.

SHERWIN LIVINGSTON HASELTINE, M.D.,
Elizabeth, N. J.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

MODERATE INDULGENCE IN ALCOHOL

To the Editor—What is the best opinion today as to what constitutes temperate use of alcoholic beverages? What quantity of alcohol in the form of spirit or wines may be imbibed daily without deleterious effect by the average individual? How many ounces of alcohol can the average individual utilize daily as heat and energy? May it be assumed that the harmful effects result from the amounts taken above the utilization point? Please recommend a small readable textbook on the subject.

JOHN HOWELL WEST, M.D., Easton, Pa.

ANSWER—Perhaps the best definition of what constitutes a temperate use of alcoholic beverages is the amount that can be taken by the individual without obvious deleterious effect. Because individuals differ so much to begin with, and because the amount of alcohol tolerated by the habituated person is so different from that which can be taken by the abstainer, it is impossible to say what can be taken safely by the average person. As every one knows, there are thousands of men and women who are made dizzy and uncomfortable by two cocktails, and then again there are persons who can drink a quart of whisky in an evening without showing any sign of alcoholism.

It is hard to say also how much alcohol the average person can safely utilize as food. As Mitchell has shown in his excellent analysis of this phase of the subject, the energy of alcohol is to a large extent available to the body. When added to a complete diet, alcohol induces a greater retention of nitrogen as well as of fat. As compared with a similar supplement of sugar, the energy of an alcoholic supplement is only about three-fourths as available, probably because of a greater specific dynamic effect. Its growth promoting power is definitely less than that of sugar. These conclusions were based on experiments on rats.

Careful studies of the absorption of alcohol and the rate of its disappearance from the blood are described in Mellanby's report to the Medical Research Committee of Great Britain. Because alcohol is excreted so slowly from the blood, the effects of repeated small doses are likely to be the same as those of one large dose. In order to avoid intoxication from repeated small doses, the interval between the drinks must be at least three hours. The effects on the brain of drinking much dilute alcohol can be the same as those of taking a small amount of the concentrated drug. The degree of intoxication seems to be related to the amount of alcohol in the blood and probably to its rate of accumulation in the body.

Water taken with alcohol was found to stimulate its absorption and to cause a more rapid and intense intoxication, but also a quicker recovery. Milk taken with alcohol seemed to be the most effective food in inhibiting intoxication.

It is not yet clear why some persons can tolerate more alcohol than others. Cushing quotes Pringsheim, who showed that part of the greater tolerance of the habituated person is due to an increased ability of the tissues to oxidize the drug. In addition the sensitivity of the brain must be altered, because Sweisheimer found that a given concentration of alcohol in the blood induces greater intoxication in an abstainer than in a habitual drinker. Some students of the subject believe that the tolerant

person absorbs less of the alcohol. It may be also that in tolerant persons the liver is able to handle a greater amount of the drug in a given time.

That the oxidative demands of the muscles play an important part in removing alcohol from the circulation was shown in the case of a physician whose boat capsized far out in an exceedingly cold lake. When he reached land, suffering terribly from the cold and shivering violently, friends wrapped him up and gave him a pint of whisky. To his surprise this man, who was practically an abstainer and always very sensitive to alcohol, experienced almost no psychic effect from the overdose of whisky. Apparently his quivering muscles utilized the stuff very rapidly.

Some discussion of individual differences in tolerance for alcohol is to be found beginning on page 263 of the excellent report by Miles on alcohol and human efficiency, based on a large amount of research work done in the Laboratory of Nutrition of the Carnegie Institution.

It can hardly be assumed that the harmful effects of alcohol result from amounts taken above the utilization point, because the studies of Miles and others show that even in small, easily oxidizable doses, alcohol depresses and interferes with mental efficiency. If in many persons it seems to increase efficiency and to stimulate, it is only because it removes inhibitions and anesthetizes to fatigue. Scientific students of the subject agree on this point.

It is hard to recommend a small readable textbook unless one knows whether the reader desires scientific information or material for sermons. A good example of a handbook for sermonizers is "A Syllabus in Alcohol Education" by Bertha Palmer, published by the National Women's Christian Temperance Union. There one learns among other things that "beer drinkers are apt to become the most un-human and beast-like of drink addicts." Beer makes its drinkers "filthy, lazy and shapeless." E. H. Williams' "Alcohol Hygiene and Legislation" published by the Goodhue Company is not quite so uplifting.

Unpalatable to uplifters but decidedly worth reading are Raymond Pearl's statistical proofs that the moderate use of alcohol does not shorten life. See the *American Mercury* 1: 213 (Feb.) 1924, also *International Clinics* 3: 27 (Sept.) 1928.

PSORIASIS

To the Editor—I have a stubborn case of psoriasis. The patient strenuously objects to ointments. Is there any medication for subcutaneous, intramuscular or intravenous use that can give this man relief? What is the latest treatment? Please omit name.

M. D., Pennsylvania.

ANSWER.—Various agents and methods apart from local treatment of the lesions have been used in the management of psoriasis. In most instances these agents are used in addition to local treatment although relief may sometimes be obtained without the aid of local therapy.

The use of salicin 1 Gm. in 1 ounce (30 cc.) of peppermint water three times daily, calcium with or without vitamin D, and thyroid by mouth is of value. The restriction of protein and of fat in the diet is also recommended. The subcutaneous injection of sodium cacodylate or the intramuscular injection of 10 cc. of blood (autohemotherapy) every five to seven days may clear up the lesions. The intramuscular injection of suspension of the patient's own scales, finely ground in alcohol, in a dose of from 1 to 4 cc. at three or four day intervals has been employed by Campbell and Frost (*Arch. Dermat. & Syph.* 22: 685 [Oct.] 1930). The emulsion consists approximately of 0.2 Gm. of psoriatic scales in 20 cc. of pure alcohol. Sodium salicylate, by intravenous injection in a 20 per cent sterile

solution at two or three dry intervals, the dose then gradually increased from 0.5 to 3 Gm, may be employed. Typhoid vaccine intravenously to produce a moderate fever reaction is also effective in some cases. Roentgen irradiation of the thymus has been used with favorable results in a group of cases treated by O. H. and H. R. Forster (*Arch Dermat & Syph* 4:639 [Nov.] 1921). The use of sodium thiosulfate, intravenously from 0.3 to 1 Gm, dissolved in 10 cc of water, given at three to seven day intervals, is also of value. General ultraviolet exposures are of particular value in the cases in which there are summer remissions.

All these methods have been employed with variable results in psoriasis. Because of the capricious response of this disease to treatment it is difficult to make a definite recommendation regarding any single agent. The general condition of the patient, and one's experience with, and the availability of a special agent used in treatment should dictate its choice. On the whole conservatism in therapy in a disease that tends to recur is the procedure of choice.

VASOMOTOR INDEX OF EXTREMITIES

To the Editor—I would appreciate your informing me of the technique in determining the vasomotor index of the extremities. We have an electrical thermometer and I have been baring the patient's extremities to the room air for thirty minutes and then recording the temperatures of each toe (solar surface) of both feet and next in order the sole dorsum, internal malleolus, external malleolus, midleg internally and midleg externally of each extremity. The oral temperature and the room temperature are then recorded. The eleven points recorded on the right and on the left are then averaged for later comparison after the intravenous injection of typhoid vaccine has been given and the patient has reached the maximal degree of oral temperature response. The legs are again bared for thirty minutes and the same procedure is carried out as before. This procedure was adopted empirically as I have never had definite instructions. What about the points I have selected to make temperature takings and getting the average for my calculation? What about the necessary preparations before beginning such as baring the legs? Please give the formula for the vasomotor index and what the normal index should be. Finally also inform me what allowance to make for difference in room temperature.

GEORGE W. SURIVER, M.D. Charleston, W. Va.

ANSWER—The ideal circumstances for determination of the vasomotor index are as follows. All medication and treatment that might influence the temperature of the skin should be discontinued the day before the test. The patient should have no fever. Smoking is prohibited. The patient should be at rest in the recumbent position in a quiet environment. The room temperature should be constant at about 72° F. and the extremities should be protected from drafts of air by a sheet placed over a cradle. The end of the compartment thus made should be open at the end near the foot of the bed.

A thermocouple junction is fixed with adhesive tape to the pulp of the distal phalanx of each of two or more digits of each extremity to be studied. Temperatures are determined every ten or fifteen minutes until they are fairly constant. Fever is then induced artificially by the intravenous injection of typhoid vaccine. For the purposes of this test a fever of from 101° to 102° F. is superior to higher temperatures. Temperatures of the skin and mouth are determined every thirty minutes until the mouth temperature is maximum. The maximum increase in the skin temperature of a particular digit minus the increase in mouth temperature at that time gives a figure which, when divided by the increase in the mouth temperature used in the first calculation, is the vasomotor index for that digit, or the increase in skin temperature due to vasodilatation for each degree of increase in the mouth temperature. It is not necessary from a clinical standpoint to determine the temperature of points other than those indicated. It is fallacious to use the mean of the increases in temperatures of various digits. Available vasodilatation for each individual digit should be determined by the test, and this is overlooked when an average of all the increases in skin temperature is used. There is no exact normal vasomotor index, in any specific instance it should exceed 2 degrees if fitness of the patient for sympathectomy is accepted. It is assumed that the correspondent's use of the vasomotor index is for determining available vasodilatation. Other information is important, such as the maximum temperature of the digits and the increase in their temperature as a consequence of fever. All three results of the study should be considered together.

Less ideal circumstances for determination of the vasomotor index are fluctuating room temperature and a noisy environment, both interfere with near basal determinations. Increasing or decreasing temperatures of the room cause an increase and a decrease, respectively, in the temperature of the skin of the digits. Argument and excitement likewise influence the temperature of the skin of the extremities.

MECHANISM OF LEUKOCYTOSIS

To the Editor—1 When a drug or any other substance when injected intravenously incites a leukocytosis does this leukocytosis result in an immunity producing reaction or coincide with such a healing effect? Or is this only an artificial effect that not necessarily produces healing? 2 When the injection of a substance intravenously incites a leukocytosis is there always or as a rule a period of leukopenia followed by an increase in the number of leukocytes? How long will the period of increased number of leukocytes persist? Or is this period subject to a considerable variation according to the substance or substances injected? 3 When a leukocytosis is induced in this way is there a decrease in the number of degenerative forms in the peripheral neutrophils so that there is a corresponding decrease in Rosenthal's degeneration index? Is this effect lasting? 4 Is the leukocytosis that is induced subject to repeated inductions so that daily or other frequent intravenous injections may be given until a high degree of leukocytosis is obtained or maintained? 5 Meranze Mendell and Meranze (*Am J M Sc* 189:639 [May] 1935) mention their use of a Jenner Giemsa stain during their study of the degenerating forms of the peripheral neutrophils. Is this stain superior to the much used Wright's stain to demonstrate the cytoplasmic changes? In what way? Will you please give me the technic in the use of this stain and the formula, if it is different from the Giemsa stain? 6 When it is desired to give sodium nucleate intramuscular injections to induce leukocytosis what dosage and strength of solution are given? How often? Is any distressing reaction incited by this solution? Please do not publish name or address.

M. D., Montana

ANSWER—1 The leukocytosis of neutrophilic type produced by intravenous injections provides a true increased delivery of these elements from the bone marrow, and if the functional need for these cells exists a more effective defense reaction should result. The cellular reaction is, of course, no measure of humoral immunity and may occur quite independently.

2 A transitory leukopenia frequently precedes the leukocytosis regardless of the nature of the material injected. According to the experiments of Doan, Zervas, Warren and Ames (*J Exper Med* 47:403 [March] 1928) this is due to an injury to the circulating granulocytes, which then sequester in the splenic parenchyma. Removal of the spleen decreases the degree and duration of the leukopenic period in rabbits. The degree and duration of leukocytosis vary markedly with the substance and dosage administered. It has been observed to persist for seventy-two hours or longer in rabbits after 1 Gm. of sodium nucleate or after 50,000,000 killed typhoid organisms, the high point (frequently 100,000) being reached at the end of twenty-four hours.

3 A leukocytosis, however induced, may be shown to reflect the bone marrow delivery of new cells through the "shift to the left" in the Arneth-Schilling index, which always occurs and persists until after an equilibrium has again been reestablished.

4 Nucleotide has been injected daily over a period as long as 116 days in rabbits with a maintained elevation in the leukocyte level throughout the observation with marked generalized marrow hyperplasia and the development of ectopic myeloid foci in kidney and spleen (Doan, C. A. The Neutropenic State, *THE JOURNAL*, July 16, 1932, p. 194). The mesenchymal tissues must have the ability to respond to stimuli, of course, in order to elicit a granulocytosis. In some clinical states, toxic or other inhibitory or destructive agents may neutralize both natural and introduced stimuli or render them ineffective.

5 The Giemsa counterstain used in conjunction with the Jenner or Wright blood stain is important in more sharply emphasizing differences in the degree of basophilia in the cytoplasm of all white blood cells. The degree of cytoplasmic basophilia is one measure of the youth of the cells in both granulocyte and lymphocyte series, and important interpretations may be based on this criterion when taken in conjunction with the character and number of granules (toxic granulations), nuclear chromatin changes, and vacuolization. Carry out the usual Wright's staining technic then dilute the saturated solution Giemsa stain 15 drops in 10 cc of distilled water and float the cover slip upside down in a watch glass containing the stain for six minutes, wash, dry and mount.

6 Sodium nucleate may be given in 0.5 to 1 Gm doses in sterile distilled water, 10 cc. intramuscularly. Adenine nucleotide may be given in comparable dosage. The pentnucleotides are prepared and available in sterile ampules, 0.7 Gm in 10 cc solution (Smith, Klein and French, Philadelphia) for intramuscular use. In properly selected and diagnosed patients, if the patient is acutely ill, this dosage should be administered every eight hours until the granulocytes are well represented in the peripheral blood again. Such dosage may be further diluted in 50 cc. of sterile saline solution and given slowly into the vein (from twenty-five to thirty minutes for 50 cc.) Alternate intramuscular and intravenous medication every eight hours is sometimes desirable. Usually no constitutional or local reaction is noted. Rarely dyspnea and substernal pain may occur from twenty to thirty minutes following the injection. No serious or fatal reactions have been reported.

NEUROLOGIC COMPLICATIONS OF DIABETES

To the Editor—A woman aged 60 was suffering from diabetes for two years. She treated herself for quite a while with some quack medicine which apparently consisted of a kind of yeast. She saw a physician five or six months ago who gave her insulin and prescribed a diabetic diet in rather general terms. The diabetes was not controlled and the patient was living mainly on cabbage and other vegetables. She came under my care by the beginning of last June. Her heart was decompensated. She had an aortic systolic murmur, aortic configuration of the heart, some broadening and density of the aorta and an aortic knob. The pulse was 96, the blood pressure 190 systolic, 90 diastolic. The specific gravity of the urine varied from 1.012 to 1.018, albumin was 0.5 per cent, sugar +++ and acetone present. The blood sugar was 300, the urea nitrogen 27. She complained about some pain in both legs and weakness of the knees. The diet was adjusted. She is now getting 1850 calories, 25 per cent above maintenance. The urine is free of sugar and acetone but still contains albumin. The last blood sugar was 176, urea nitrogen 15, carbon dioxide combining power 53, volumes per cent. The pulse rate is 78, the blood pressure is 160/90 and the heart is compensated. In short, diabetic heart and kidney conditions are under control. There is, however, an increasing weakness of the legs with torturing cramps and pains particularly during the night. The circulation in the legs is sufficient. The patellar and ankle jerks are abolished and the flexors of the legs markedly weakened. The Babinski reflex is negative. Romberg's sign is present. There is impairment of the sense of vibration. The gait is ataxic. A neurologist agrees with me that all the symptoms of a subacute combined degeneration are present. There are no signs of pernicious anemia, however. Acidity after test breakfast was free hydrochloric acid 32 combined 12, total 82. Blood examination revealed 4,500,000 red cells without pathologic forms, hemoglobin 80 per cent, color index 0.9, leukocytes 10,000 with a slight shift to the left, monocytes 6 per cent, eosinophils 6 per cent, basophils 2 per cent. The patient has a slight cystitis which may account for the white blood picture. She is getting 50 units of insulin, digitalis in maintenance doses, a preparation of vitamins A, B and D to combat any deficiency, and sedatives. Diathermy helped a little but could not be continued as the patient left the hospital. How can one explain the changes in the cord? The patient claims that her pain started when she was put on insulin. Are insulin reactions of this kind possible? What can be done for the improvement of her condition? Please omit name.

M. D. New York

ANSWER—Insulin prevents rather than causes neurologic complications in the course of diabetes if it is used with discretion. In the differential diagnosis of this case, must one not consider a diabetic neuritis as possible? Surely one would like to exclude any circulatory deficiency in the extremities with the use of the oscillogram, prove that hypoglycemia is absent, and investigate the possibility of syphilis of the central nervous system or a tumor of the spinal cord.

While constantly alert for new evidence as to etiology, treatment would proceed on the basis of neuritis as responsible in whole or in part for most of the symptoms. The indication therefore would be to treat the diabetes energetically, being sure to take pains that hypoglycemia is avoided and that on the other hand, a liberal supply of food is furnished. The diet would contain fruit and vegetables in abundance, yeast concentrate or some other source of vitamin B, cod liver oil on the ground that possibly more vitamins are indicated than have been furnished and despite the result of the blood examination one might even use liver extract with benefit. Finally, physical therapy might be employed depending chiefly on heat and using exercise with caution. Fractures of the spine and tumors of the spinal cord are rare complications in diabetes; the commoner complication is neuritis.

EFFECTS OF EXERCISE ON BLOOD PRESSURE

To the Editor—What is the normal effect of exercise on the diastolic and systolic blood pressure? Please omit name.

M. D. Michigan

ANSWER—The normal effects of exercise on the arterial tension vary with the type, duration and intensity of the exertion. Brief and moderate exertion, such as climbing a short flight of steps slowly or bending to the floor from twelve to fifteen times, causes a rise in both the systolic and the diastolic tension and an acceleration of the cardiac rate. The rise is about 10 to 20 mm. systolic and 5 to 10 mm. diastolic with considerable variation in either direction. In normal individuals the pulse and blood pressure return to preexertion levels well within two minutes. This type of response is used as a criterion of circulatory fitness but the interpretation must include consideration of other factors such as the muscular condition of the patient, the age and the emotional state. Thomas Addis (*Blood Pressure and Pulse Rate Reactions*, *Arch. Int. Med.* 30:240 [Aug.] 1922) studied the circulatory responses to exertion of 300 normal persons and found that the increase in both pulse rate and pulse pressure varied directly with the amount of work. The rise of the systolic tension is greater than that of the diastolic, with an increase in the cardiac output and therefore an elevated pulse pressure. In this normal

circulatory response the pulse acceleration and deceleration are both more prompt than the changes in the arterial tension, the latter lags behind both in rising and in falling with rest. Exhausting, violent and excessive exertion may result in a fall in the diastolic level, which may be followed by depression of the systolic pressure if the heart has been overtaxed and collapse impends.

It has been shown (Scott, V. T. *Study of Effects of Daily Exercise on Pulse and Arterial Pressure*, *Mil. Surgeon* 55:334 [Sept.] 1924) that the institution of regular exercise in poorly trained persons such as military drilling with new recruits results in a gradual fall in the diastolic pressure but that there is no essential variation in the systolic tension.

The arterial tension is so labile and is affected by so many variables such as emotional stresses, environmental temperature, digestion and mental activity (mental work in contrast to emotional activity), that one must be very cautious in interpreting the significance of moderate fluctuations.

DIFFERENTIAL DIAGNOSIS OF ABDOMINAL PAIN

To the Editor—A man, aged 40, weight 165 pounds (75 Kg), height 5 feet 9 inches (175 cm) has been admitted to the hospital twice for severe attacks of epigastric pain and nausea. The pain was localized 1 or 2 inches above the umbilicus with some radiation to the right. Rigidity was present during these attacks which lasted about twelve hours with subsidence in one or two days. Two years previously the patient had symptoms and signs suggestive of acute appendicitis but the appendix on removal proved to be normal both grossly and microscopically. The patient continues to complain of a constant mild deep seated tenderness about 2 inches above McBurney's point. Mild tenderness in the localized area just above the umbilicus persists. During one of the acute attacks the patient's temperature remained around 101° F. for eighteen hours. The leukocyte count was 13,000 and the systolic blood pressure dropped about 15 mm. The rest of the physical examination and history is not significant. Laboratory examinations included the following: The Graham-Cole test was negative. A flat plate of the abdomen during one of these attacks showed a small amount of gas in the small bowel loop suggestive of stasis. The stomach and duodenum were normal under the fluoroscope. An intravenous pyelogram was negative. Roentgenograms of the long bones and skull were negative. Urinalysis and blood sugars were repeatedly negative. A differential blood count was repeatedly normal. An electrocardiogram taken after one of these acute attacks showed only a moderate left axis deviation. Blood and spinal fluid Wassermann reactions and colloidal gold curves are negative. Blood urea, erythrocyte sedimentation rate and dextrose tolerance curves are normal. Blood phosphorus (serum) determinations gave values of 4.4 and 4.2 mg. per hundred cubic centimeters. Five determinations of the blood calcium gave values ranging from 12 to 15 mg. per hundred cubic centimeters. Quantitative determination of plasma proteins gave the following values: fibrinogen 0.4 Gm. per 10,000 plasma, globulin 2 Gm. per 10,000 plasma, albumin 4.8 Gm. per 10,000 plasma, total 7.2 Gm. per 10,000 plasma. Kidney dilution concentration and phenolsulfonphthalein tests gave normal results. The bromsulphalein liver function test showed no dye present after half an hour (normal response). On a diet of 0.5 Gm. of calcium daily the average daily calcium excretion was 0.31 Gm. This was about twice that excreted by a control convalescent herniotomy patient of the same age and approximately same type of stature and physical condition. The blood cholesterol was 240 and 290 mg. per hundred cubic centimeters on two separate determinations. The basal metabolism was -1. Serum bilirubin determinations gave values of 0.23 and 0.28 mg. per hundred cubic centimeters. Any suggestions or references to the literature will be appreciated.

INTERN, Minnesota

ANSWER—Several conditions suggest themselves some of which are apparently ruled out. It is fairly well assured that in the continued absence of red blood corpuscles in the urine renal calculus is ruled out, and by the pyelogram that ureteral obstruction does not exist. This however is not absolute and further examination of the urine passed immediately after an attack is advisable especially in view of the high blood calcium. Marked tenderness in the right upper quadrant can speak for biliary tract disease especially in the presence of the temperature elevation and leukocytosis. It may be possible to obtain a plate during one of these attacks taken with low milliamperage and a long exposure that will show a distended gallbladder. Allergic disease of the gallbladder must be considered seriously. An inquiry into a family history of allergy is obtained in half or more of all cases. Other disturbances as urticaria, canker sores and intermittent bowel distress or diarrhea should be looked for. It is much more difficult to prove the possibility of pancreatitis. Recent reports in the literature point to the increased frequency of this condition with or without pancreatic calculi. Occasionally a glycosuria may occur. The blood sugar need not be elevated. There need be no evidences of biliary tract involvement. An enlarged duodenal loop visualized with a barium sulfate meal is suggestive of enlargement of the head of the pancreas. In the presence of a negative dextrose tolerance test the probability of pancreatic involvement is lessened but not entirely absent. A final suggestion is that of the possibility of terminal ileitis. While not probable from the

data submitted, its presence can be determined by watching the progress of a barium sulfate meal at three, six and nine hour intervals and noting the caliber and the regularity of the wall of the terminal ileum

DEATH FROM SULFUR DIOXIDE

To the Editor—I am interested in finding the cause of death in a person exposed to sulfur dioxide. In a book by Henderson and Haggard entitled *Noxious Gases and the Principles of Respiration Influencing Their Action* page 120 it is stated that consequently it frequently happens that a man who appears to be only slightly affected is allowed or told to make some movement such as sitting up in bed so that a physician may listen to roles in his lungs and as the result of this slight exertion he falls back dead. Please explain to me the exact pathology and the cause of death suggested in this statement. I do not have access to this book at the present time. When sulfur dioxide is breathed I understand that the local effect is due to the irritating action of sulfuric and sulfurous acids and that these acids do not cause any general systemic effect. I understand further that the salts of these acids sulfates and sulfites are absorbed into the blood stream and do cause a general systemic effect which may prove fatal by means of paralyzing certain nerve centers (H. Klonka experimenting on frogs with sulfur dioxide as reported by Mellor in 1930). The use of sulfates as a food preservative is now illegal. Why? Please omit name.

M D New York.

ANSWER—The quotation from Henderson and Haggard's book is taken from a paragraph which reads as follows: "As the edema progresses, the diffusion of carbon dioxide is interfered with to an increasing extent. The pressure of carbon dioxide in the arterial blood rises, probably the blood alkali also decreases, while anoxemia becomes more and more intense, and all three conditions contribute to the intense air hunger. The more marked symptoms depend upon the excessive pressure of carbon dioxide in the arterial blood but the more serious damage results from the deficiency of oxygen. The asphyxia of lung edema arising from irritant gases, therefore, is more dangerous than the superficial signs indicate. Consequently it frequently happens that a man who appears to be only slightly affected is allowed, or told, to make some movement, such as sitting up in bed so that a physician may listen to the rales in his lungs, and as the result of this slight exertion he falls back dead. This is probably the failure of an overworked and asphyxiated heart." It seems reasonable to accept the last statement in this quotation as adequate explanation of the cause of death under the circumstances.

An objection to the use of sulfites (not sulfates) for a food preservative, especially meat products seems to be that owing to the fresh color thus given meat products, various forms of adulteration may be favored.

PARESTHESIAS

To the Editor—Would you kindly suggest the diagnostic possibilities in the following case? A man aged 40 previously healthy and not addicted to alcohol and with no history of contact with lead or other toxic metals noticed ten days ago that his feet felt as though his shoes were filled with sand. A couple of days later he noticed a numb feeling which has gradually spread upward from the feet the upper limits remaining stationary now for several days to the groin in front and about to the level of the first or second lumbar spine behind. In addition to this feeling of numbness he has the sensation of his socks being crumpled up and a certain amount of subjective stiffness in the knees. There is no pain and no objective sensory loss whatever and he continues his work as a blacksmith without trouble. The reflexes are normal there is no ataxia and no weakness. The blood picture is normal and the Kahn reaction is negative. He is decidedly not the neurotic or hysterical type of individual.

J B STOLL M D Clay Center Kan

ANSWER—From the history, the man has paresthesias of both lower extremities consisting of tingling, numbness and sensations of heaviness. There are two systems, when affected which may cause such paresthesias. One is the peripheral vascular system and the other is the nervous system especially the roots and peripheral nerves of the lumbosacral region (in this case). It is suggested that vascular disease be ruled out by palpation of dorsalis pedis and popliteal pulsations, that histamine be injected intracutaneously for the development of a wheal and that postural studies be made with the extremities hanging in the dependent position and then elevated to the recumbent position. It is further suggested that the patient be reexamined daily for new signs and symptoms indicating involvement of the peripheral nerves roots or spinal cord. A careful manometric and serologic study of the spinal fluid should be made in order to rule out spinal block. It is impossible to give any definite opinion as to what actual entity is causing the symptoms from the description. There are many diseases that may cause this symptom complex and until more signs and symptoms develop one will not be able to

make a definite conclusion. At times paresthesias of this kind may disappear just as insidiously as they came on. When paresthesias are confined to the external lateral surface of the thighs the condition is known as *meralgia paraesthetica*. It is possible that this patient may have a subacute atypical arthritis of both knees.

POSSIBLE INFECTION FROM POORLY LAUNDERED LINENS

To the Editor—Referring to the interesting paper, *Scabies Among the Well to Do* (THE JOURNAL February 29) by Dr J H Stokes I would be glad if the following considerations would find a place in one of your next editions. An important role in the dangers of hotel and traveling life in this country is played by the general habit or better said by the general neglect not to boil used bed linen and towels in industrial laundries as well as in private homes. That is done as a routine on the other side but not in the elsewhere so far advanced hygienic United States of America. Here linen is never boiled only washed and ironed. The consequence is reinfestation of the traveling public by apparently clean bed linen and towels as Dr Stokes proved in his paper. I think it would be a good job for the profession or for public health authorities to exercise some pressure on the laundry industry and some influence on the general public always to boil used linen for a sufficient time before ironing it. Plain washing even with addition of some disinfecting lotions and ironing will never give sure protection against later contamination with some transmissible infection.

LEOPOLD SCHWARZ M D Richfield Springs N Y

ANSWER—In general there are wide differences in laundering, ranging from the use of the mangle on linens without washing to the use of disinfectants so destructive, temperatures and washing methods so high and vigorous that the life of the linens to say nothing of any possible contained parasites, is materially shortened. The elevation of linens in the process of washing to the boiling temperature in the presence of a mild alkali would be a desirable universal practice. It is probable that the fungi alone which survive less thoroughgoing laundry handling are responsible for the transmission of fungous infections. We know of no systematic study that covers this point. As far as the acarus of scabies is concerned the adult would not survive laundering in the ordinary steam laundry washer plus the hot mangle. It seems probable that the blanket is responsible for more trouble than the linen. A laundry in Philadelphia has recently circularized the physicians of the city with an abstract from a study of the bacteriology of pillows which suggests that they can become accumulating grounds for pyogens of various types. Clothing made of silk or wool which is brought into direct contact with the skins of susceptible persons can apparently carry pyogenic infections. This is an element of some importance in acnes of the back shoulders and chest in young women and in athletes ("sweater acne").

It might be that bed linen not subjected to boiling might serve as a source of occasional infection of susceptible persons with pyogenic organisms. Here again, however a more systematic investigation would be needed as a basis for any recommendations.

MAZOPLASIA OF BREAST

To the Editor—I have a puzzling case that has been diagnosed by a number of specialists in pathology and tissue diseases. No diagnosis pointed to cancer but various names were given as a diagnosis the latest was chronic periductal mammary fibrosis. In short the history duration is approximately three years beginning with pain in the breasts in a woman aged 38. The menstrual history is negative with the significant fact that for one or two days during the periods the pain in the breasts becomes less severe. In the last five years both breasts have enlarged and become firm with a diffuse thickening with no palpable tumor masses. There are a few slightly thickened and enlarged nodes in the left axilla. In the last six months the pain in the breasts has been almost constant. There was some serous discharge from the nipples but lately there has been no discharge whatever. Roentgen examination shows no tumor masses. The blood sugar is normal and Wassermann tests are constantly 3 plus with extensive antisyphilitic therapy. The pain in the breasts has continued despite the antisyphilitic treatments. The patient's weight has remained constant and physical examination and pelvic examination are entirely normal. Can you give me any clues as to treatment for the relief of discomfort and what the future for the patient may contain? Please omit name.

M D, New York

ANSWER—The patient is probably suffering from mazoplasia. This is a condition in which there is a hyperplasia of the connective tissue and epithelium of the mammary glands and represents an overactivity of these elements when normally they should be at rest. This condition is undoubtedly related to some disturbance in endocrine function, the exact nature of which is not fully understood. In some cases particularly those in which there is a short and scanty menstrual period the administration of one of the estrogens either by mouth or preferably by hypodermic injection may lead to relief of pain.

Book Notices

Social Security in the United States. An Analysis and Appraisal of the Federal Social Security Act. By Paul H. Douglas, Professor of Economics, The University of Chicago. Cloth. Price \$3. Pp 384. New York & London: Whittlesey House, McCraw Hill Book Company, Inc. 1936.

In the opinion of the author, the federal social security act was, at the time of its enactment, the most important statute passed under the present national administration but full of weaknesses, strikingly incomplete, and merely a first step, which must soon be followed by others. The criteria by which he measures the act and prescribes for its shortcomings, he does not state. "Social security" is neither defined nor described. As to the optimum of social security for which the people may reasonably strive, he expresses no opinion. The limit below which social security cannot safely fall is not stated. How far it is safe to go in attempting to establish social security for some classes of the people, with necessary incidental impairment of the rights and privileges of others, the author does not say. In the absence of an understanding between the author and his readers concerning such matters as these his appraisal of the act loses much of its value. It becomes merely the author's unsupported dictum.

So far as can be judged from his book the author is strongly in favor of the concentration of more authority in the federal government, if not under the present constitution or by evading its intent, then by amending it. Under the enlarged social security scheme proposed by the author the states might easily become nothing more than vassals of the federal government. The federal government, if unable to dominate by direct constitutional authority, would control through its taxing power mulcting the people of the several states of any amount of money the central government might desire and distributing the money thus collected as subsidies, bonuses or bribes to compel or induce the subservient states to do its bidding. The social security act is already replete with federal requirements to which a state must subject itself and its people before it can obtain from the federal treasury money appropriated under authority of the act previously exacted by the federal government of the people of the states. The author however would go further and have the federal Social Security Board given power to see that adequate old age pensions are paid by the several states but how the board is to determine in each case the adequacy or inadequacy of an old age pension, and the nature of the "power" with which the board is to be vested in order to enable it to compel compliance with its mandates, the author does not say. The author would have the federal administrative authorities "vested with the power to lay down minimum standards for the government of the several states in the selection, tenure and promotion of those state and local officials charged with the administration of various sections of the social security act, a civil service ideal that the federal government seems not yet to have attained after many years of striving even in the management of its own affairs.

If, however, the author would have Congress augment the authority of federal officials over the governments of the several states, he is apparently willing to pay the price and would add largely to the appropriations that the social security act now authorizes Congress to make, returning to the people of the several states as subsidies, bonuses or bribes for good

behavior some or all of the money collected through federal levies, direct or indirect, previously imposed on those very same people. Federal subventions for old age pensions should be increased, the author says, from \$15 a month to at least \$20 a month. The social security board should be given "a considerable sum of money to grant as outright aid for pensions to states which are particularly poor." The federal government should pay at least a portion of the costs of the unearned annuities of the older workers, now authorized by the social security act, and not saddle such costs on the younger workers. There the author's consideration for the younger workers seems to end, for he proposes that the social security act be so amended as to allow aged annuitants to continue their employment in industry while receiving their annuities and he would thus limit opportunities for the younger generation as it reaches an employable age. Additional federal funds should be obtained, according to the author, for aiding states with high unemployment rates to maintain minimum benefits and to provide benefits for workers who migrate from state to state. If the constitutionality of the present federal system of old age insurance is upheld, the existing federal-state tax offset system of unemployment insurance, if the author is to have his way, would be transformed into a strictly federal system. If the constitutionality of both the federal system of old age insurance and the federal-state tax offset system of unemployment insurance is denied, the author suggests that the federal government may still establish a federal-state system of unemployment insurance through a 100 per cent grant-in-aid to the states, to induce them to maintain unemployment insurance in accordance with standards presumably dictated and enforced by the federal government. The author would have the present federal grants in behalf of mothers' pensions increased so as to meet one half of the total cost, instead of one third as at present.

A system of health insurance is proposed which the author believes 'will provide a more even distribution of the costs of medical care and also a cash benefit to compensate in part for the loss of earnings.' Health insurance, he believes, will sweep a much larger proportion of the population into the ranks of paying patients than is at present the case, and despite the opposition of the official leaders of the medical profession it would be of real economic benefit to the rank and file of practitioners, but he submits nothing to show the relation of costs to benefits, primary and ultimate. Whether he would have the states made to comply with the federal will with respect to health insurance through subsidies, bonuses and bribes, or brought under federal control through a federal-state tax rebate system or, as the author proposes with respect to old age pensions and state administrative service, simply empower the social security board to make the state do what the board may determine with respect to the matter, the author does not state.

There would be no difficulty, if the author's views are correct, in meeting the large increase in the expenses of the federal government necessary to carry into effect his suggestions for a larger participation in his extended social security scheme, for he has a ready formula whereby the increase may be met.

Nothing will be gained however [he says] if these funds are then derived from taxes on consumption. In order that these costs may be borne with the least sacrifice they should be met from taxes on excess profits and on the upper brackets of personal incomes. For the workers are already severely burdened both by the present system of financing social insurance and by the numerous state sales taxes.

But if we are to provide real social security for the employed population, according to the author, it is not enough to insure against the interruptions of working class incomes, it is necessary also to raise the levels of those incomes 'to an adequate amount.' Fortunately, the author has a simple formula for accomplishing this end, stated as follows:

The best way of meeting this situation as long as we retain the capitalistic system is to increase the level of wages itself. This can be done by an increase in the technical efficiency of industry by a greater growth in the quantity of capital than of labor with a consequent increase in the marginal productivity of the latter and also by a decrease in the power of monopolies and of all impediments in the way of price competition which cause labor to be paid less than its net social productive value.

If the author has devised any method by which this system of raising necessary funds can be successfully applied to capital, industry or labor, his services should be in great demand.

The author is probably at his worst when he discusses the legal aspects of the social security act. His direct statement that the constitutionality of the Sheppard-Towner Maternity and Infancy Act was upheld by the Supreme Court in the case of *Massachusetts v. Mellon*, 262 U. S. 447, 43 Sup. Ct. 597, is directly contrary to the fact, and when the author implies that a phrase used in that opinion is "a direct and positive affirmation of the constitutionality of federal aid," he ignores the purport of the decision as a whole. Incidentally, when, in support of the Sheppard-Towner Maternity and Infancy Act and impliedly of federal subsidies generally, he cites figures that the reader who is not technically informed may construe as evidence of benefit derived from the act named and ignores a vast mass of figures to the contrary, he lays himself open to a charge of special pleading. When he implies that our written constitution is so inflexible as to "confine us to the straitjacket of narrow powers" and to force "those who are seeking to adapt the activities of the government to the needs of the times" to resort to political contrivances and legal fictions, he does so either in ignorance of the provisions of the constitution or ignoring them, for the constitution requires nothing of any one except compliance to its agreed terms, which make ample provision for amending the instrument in an honest and open and above board way, as and when circumstances render it expedient to do so. If "those who are seeking to adapt the activities of the government to the needs of the times" will present their views to the people through the orderly process laid down by the constitution, the people themselves will determine whether any such adaptation as is proposed is in the public interest.

This book contains an admirable historical analysis of the federal social security act. As an appraisal of the act and as a proposal for its future enlargement, however, it must be looked on primarily as propaganda unsupported by adequate evidence.

Kurzwellentherapie Von Dr. Josef Kowarschik, Primararzt und Vorstand des Institutes für Physikalische Therapie im Krankenhaus der Stadt Wien. Paper. Price 9.60 marks. Pp. 140 with 147 illustrations. Vienna: Julius Springer 1936.

This monograph should prove of value to physicians interested in such a controversial field as short wave diathermy. The first two chapters are devoted exclusively to the physics of high frequency currents and the apparatus. Many physicians find physics an uninteresting topic or too much involved in higher mathematics for a thorough appreciation. However, Kowarschik has the happy faculty of dealing with this subject in a clear and simple way. His points are clarified by the use of simple analogies. The technic of application is well outlined and illustrated in the third chapter. For those physicians new to this field of therapy, this chapter should prove of real value. One should be warned however against such unfortunate statements as that the farther the electrodes are from the body the greater will be the depth of heating. Again the impression is given that one can measure the dosage delivered to the patient. At present this is not possible. The suggestion that ten minutes' treatment may prove efficient would hardly seem warranted. It is refreshing to find the author stating that as yet no special wavelength has been found for specific diseases which corroborates the observations of many English and American workers. Kowarschik stresses the need for good apparatus in giving general body treatments and states that wavelengths of from 12 to 30 meters serve this purpose best. He suggests the use of some absorbent material to prevent the accumulation of moisture on the skin surface, which is frequently the cause of most electrical burns. It is interesting to note that, in addition to the usual pad (condenser) type of electrode application, Kowarschik advocates the use of the coil electrode, which is quite similar to the method popularized in this country by the inductive type of heating. He gives a few technics that will be new to many physicians in this country.

The fourth chapter is given over to the biologic action of short waves. This is the weak spot of the book. Experiments *in vitro* are cited the accuracy of which is not doubted which have been repeated in this country many times. These experiments have been used to show that certain wavelengths have selective heating effect. That these phantom model experiments cannot be carried over in *in vivo* experiments has been shown by many workers in various countries. The author states that colloidal suspensions can be selectively heated. This is true but can be explained by the so-called point heating of Esau. Few

research workers in this country are willing to accept the theory of the killing of bacteria in human tissues by such a mechanism. He states that it is difficult to prove any specific electrical effect. All the physiologic effects cited are readily explainable as the effort of the body to eliminate heat that is generated in the tissues. The author states that certain wavelengths have a greater effect on the bacteria than do others. This again is a statement that would not seem to hold in the light of the work of other workers. He does state, however, that nothing very definite has been established, owing to the variable nature of the different bacteria. That short waves have a decided action on neoplasms of human beings is a statement that cannot be accepted without demanding some definite evidence, certainly none seems to be forthcoming. The chapter closes with an excellent warning about the danger of burns, both superficial and deep. The author does not give the impression that burns are not possible with this therapy, as so many physicians have been led to believe. The fifth chapter gives a list of diseases that are amenable to short wave therapy and here the author is rather optimistic.

The monograph is well written, clear, concise and well illustrated. If one is familiar with the entire literature of short wave therapy he is well fortified against misinterpretation of the experimental material presented. The novice, on the other hand, would do well to familiarize himself well with current literature to avoid the many pitfalls presented in the fourth chapter.

The Next Hundred Years: The Unfinished Business of Science. By C. C. Furnas. Associate Professor of Chemical Engineering, Yale University. Cloth. Price \$3. Pp. 434. Baltimore: Williams & Wilkins Company 1936.

In this volume an author with a fine sense of satire indicates the way in which science has failed to meet its responsibilities and obligations. As might be expected, a man without medical training is likely to be a little weak in his approach to the medical problem, as, indeed, he is weak in his approach to the problems of other fields of science where he has had insufficient training. He is inclined to believe in compulsory sickness insurance or even socialized medicine as the solution to the problem of medical distribution and medical care for all the people, and it is apparent that his reading in these matters is exceedingly limited and that the limitations have been still further restricted to the literature conferred on him by propagandists. Nevertheless, the book is exceedingly well written and most provocative and stimulating in relationship to the paths which research must follow in the future.

The Adopted Child. By Eleanor Garrigue-Gallagher. Cloth. Price \$2.50. Pp. 291. New York: Reynal & Hitchcock, Inc. 1936.

This is a dispassionate yet warmly human discussion of the problems of the adopted child and the adoptive parents. The author considers both with unusual understanding not forgetting the interest of society in the correct solution of the problems involved in the placing of children who for one reason or another, usually illegitimacy, cannot be kept with their own parents. She has no illusions about the very real disadvantages suffered by the child born out of wedlock and she regards with scorn the sentimentality involved in deleting the record of illegitimacy from the official certificate of birth. She differs sharply with many of the practices now current in the placing of children especially the granting of power to make and enforce rules to so-called state boards of control. She considers that two states at least, in which social progress by legislation has been greatly extolled, have achieved nothing but the ineptitude of entrenched bureaucracy. She condemns particularly the three month nursing rule under which unmarried mothers must nurse their babies for three months, thus postponing placement to no good purpose. On the other hand she is not wholly convinced that everything which goes under the name of social work by voluntary agencies is necessarily as valuable as its sponsors would like to make it appear. She is bold enough to declare her belief that social workers are not omniscient and should not be so regarded even by themselves. Yet she demands good social case work for the placement of babies meanwhile announcing the heretical—in this day and age—dictum that intelligence and experience automatically qualify a volunteer worker without the necessity for elaborate academic training. Knowing intimately the problems involved

in adoption, viewing them sensibly and realistically, she has the courage to express her views without compromise. The book is a valuable contribution and should be welcomed by adoptive parents, either actual or prospective, by open minded social workers and legislators, and by physicians and nurses. The medical chapters are excellent. There is a detailed description of the technique at the famous Evanston nursery. The Cradle, both social and medical technique being well explained. Appendices describe the procedure of adoption in Illinois in some detail, in the other states in briefer form, and in other countries. This is a book to inform and to stimulate thought, and it will be a hard hearted reader who will not be moved by some of its passages.

Traité d'urologie. Par C. Marion, professeur de clinique urologique à la Faculté de médecine de Paris. In two volumes. Third edition. Cloth. Price 220 francs per vol. Pp 687 680 1232 with 608 illustrations. Paris: Masson & Cie 1935.

In general this treatise on urology is quite complete and will be found valuable both as a text and as a reference book. The two volumes contain sections on anatomy, examination, symptomatology, urethroscopy and cystoscopy, pathology and treatment, urologic formulas and operative technique. The arrangement of the material is unusual and is not without merit. The various lesions are considered under the heading of general and etiologic factors, symptomatology, pathology with diagnosis and treatment. The surgical treatment is considered last in a separate chapter comprising about 20 per cent of the contents. It is an excellent outline of the subject and reflects the unusual surgical knowledge of the author. The clinical consideration of surgical diseases of the kidney occupies a much larger proportion of the volume than is usually found in similar publications. While various items are stressed which do not usually appear in the average American or English books on urology, this different point of view will be found most valuable. The pages devoted to laboratory diagnosis and tuberculosis are especially recommended. The urethroscopic and cystoscopic colored plates are unusually complete. To those who are accustomed to using the old French calibration the new calibration in which the graduations are by $\frac{1}{16}$ mm. is confusing. There are several objections which could be raised from the American urologist's standpoint. Vesiculography is described as done only by vasotomy, and pneumopyelography is recommended in calculous disease. More serious is the reservation of intravenous urography for only those cases in which ureteral catheterization is impossible, rather than its routine employment preliminary to cystoscopy as we are accustomed to use it. The great effect of dehydration as a cause of postoperative anuria is not mentioned. The malignant nature of bladder papillomas is not stressed even though the similar tumor of the renal pelvis is considered malignant and nephroureterectomy is advised. On transurethral prostatic resection there is an inadequate section—four pages—which coincides with the statement in the text that "resection does not greatly increase the possibilities of cure of prostatic hypertrophy". Similarly there is no mention of resection under discussion of malignancy of the prostate gland and suprapubic operation is advised. The technique of nephrolithotomy is much more carefully described than that of pyelolithotomy even though the latter is recommended. The section on the care of hypospadias and cryptorchidism is poor, as modern operations are not described. The ketogenic diet is found among the urologic formulas where it probably belongs. There is appended a quite complete index. Altogether it is an excellent treatise on the subject of urology and should merit careful consideration and frequent reference.

The Undaunted. By Alan Hart. Cloth. Price \$2.50. Pp 310. New York: W. W. Norton & Company, Inc. 1936.

This is the second novel by a far western physician to be published by the present publisher. It circulates around the thesis that present medicine and medical practice are wasteful, that the physician who would engage in research has a difficult time and that life in general is no bed of roses. Nevertheless, it gives a better picture of the medical scene than most medical novels and for that very reason is likely to be read with interest by many physicians. The author has not, however, developed as yet the ability to tell a story, and that ability is the prime requisite for success in the production of a novel.

From a Surgeon's Journal 1915-1918. By Harvey Cushing. Cloth. Price \$5. Pp 534 with 35 illustrations. Boston: Little Brown & Company 1936.

Much of this volume has already been published in the *Atlantic Monthly*, where it attracted wide attention. The place of Harvey Cushing as a man of letters in the field of medicine is well established. No one doubts his ability to observe and to write brilliantly of what he sees. His war diary, as assembled in this volume, has been culled from a vast amount of material in order to make a book readable by physicians and laymen alike. No doubt there have been removed sections dealing with the horrible and disgusting as well as other sections dealing with the detail of medical and surgical procedure during the war. The result is a volume which is exceedingly readable and which in general maintains interest. Reviewers who have already commented on this volume seem to have been disturbed most by the failure of Dr. Cushing to discuss from a philosopher's point of view the evils and the horrors of war. They forget, no doubt, that the surgeon during war is confronted with a task which leaves little opportunity for philosophy or soliloquy. He must repair the shattered bodies that come to him in order to get them back to the front as soon as possible. Should he pause to disturb himself with reflection on the performance, he would not be qualified to continue in that performance. As a scientific observer Dr. Cushing has concerned himself primarily with presenting an accurate picture of his own work. His eminence in the medical profession and his skill in his chosen field are such that his opportunities for association with the great and the near-great in all the warring nations were exceptional. This is apparent in his book and gives it added interest. It is inconceivable that any surgeon, regardless of how little he may read in general, could fail to be interested by this superb volume.

Treatment of Fractures in General Practice. By W. H. Ogilvie, M.D., M.Ch., F.R.C.S. Volumes I and II. Second edition. Cloth. Price 2s. 6d. per vol. Pp 108 109 180 with 37 illustrations. London: John Bale Sons & Danielsson Ltd. 1936.

These two pocket-size books contain a large amount of material that has been crystallized for the general practitioner. An attempt has been made to give the practical outline of fracture treatment in the confines of 180 pages. The author has included his own experience and the accepted practices on the continent, including the teaching of Böhler of Vienna. In volume I the general principles of fracture treatment are outlined and the treatment of fractures of the upper extremities and shoulder girdle is given. The author believes that the periosteum is a fibrous limiting membrane, carrying nourishment to the surface layers of bone, and, during the growth period, firmly adherent to the superficial osteoblasts. He does not believe that periosteum itself is osteogenic. Volume II includes fractures of the lower extremities and pelvis. An illustration of the Watson Jones modification of the Smith-Petersen pin does not rightly belong in a book of this small size. It is regrettable that the author did not include a description of the Leadbetter method of closed reduction of fracture of the neck of the femur. The illustrations are highly diagrammatic, which adds to their teaching value. The little books furnish interesting reading, most of which is authoritative and should be helpful.

Great Doctors of the Nineteenth Century. By Sir William Hale White, K.B.E., M.D., LL.D., Consulting Physician to Guy's Hospital. Cloth. Price \$5. 15s. Pp 325. Baltimore: William Wood & Company 1935.

The title of this book is hardly accurate, since it is concerned not with all great doctors of the nineteenth century but specifically with seventeen prominent British physicians and surgeons. It begins with Edward Jenner and includes as well Sir Astley Paston Cooper, Sir Charles Bell, Richard Bright, Marshall Hall, Thomas Addison, William Stokes, Sir James Young Simpson, Sir James Paget, Sir William Bowman, Sir John Simon, Sir William Withey Gull, Sir Samuel Wilks, Lord Lister, John Hughlings Jackson, Sir Patrick Manson and Sir Donald Ross. The biographies are nicely written, sharp, illustrated with anecdotes and indicative of the contributions to science which made their subjects eminent. Among the best of the biographies is that dealing with Sir James Young Simpson, but all of them are more than worthy the time of any physician interested in medical history.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Hodgkin's Disease Attributed to Trauma—The employee, during the course of employment, received a blow on the side or back of his neck. Thereafter he complained that his neck and throat hurt him and his neck appeared to be swollen. About seven months after the injury, the employee died from Hodgkin's disease and his widow applied for compensation under the workmen's compensation act of Kentucky. The industrial board dismissed the application and, after the circuit court had affirmed the action of the commission, the claimant appealed to the Court of Appeals of Kentucky.

A chiropractor who treated the employee for a period of two weeks shortly after the injury testified that he found an enlargement of the cervical glands and that the left half of the thyroid gland was much swollen. He testified that a bruise could have caused the swelling of the glands but that he had made no diagnosis. When asked if the patient was suffering from Hodgkin's disease, he replied "Yes sir, forerunners" [sic]. During the last month of his life the employee was under the treatment of a physician who testified that the symptoms he found were difficult breathing, temperature between 101 and 102 degrees, a considerable lump on the left side of the neck with some swelling on the other side, and that the cervical lymph nodes were involved. He testified that the cause of death was Hodgkin's disease and that from the history he obtained he could trace the disease only to the blow received by the employee on his neck. Three other physicians, described by the court as being qualified from experience and training to speak on the subject, testified that there is no relation between Hodgkin's disease and traumatic injury.

In denying the application for compensation, said the Court of Appeals, the compensation board found as a matter of fact that the employee died as the result of Hodgkin's disease, which had no relation to the blow the employee received on his neck. With this finding the court agreed and affirmed the judgment of the circuit court for the employer—*Hale v State Highway Commission (Ky)* 91 S IV (2d) 23.

Malpractice Death from Asphyxiation Attributed to Negligent Administration of Anesthetic—The defendant, a physician, administered the anesthetic during an operation performed on Mrs. Beulah Forbis. The patient died on the operating table and the husband and daughter of the deceased sued the defendant, claiming that the patient died from asphyxiation as the result of his negligent administration of the anesthetic. The superior court, Los Angeles county, gave judgment for the plaintiffs and the defendant appealed to the district court of appeal, second district, division 1, where judgment of the trial court was reversed (45 P (2d) 215, abstracted, THE JOURNAL, Dec. 28, 1935, p. 2182). The case then came before the Supreme Court of California on appeal.

According to the evidence said the Supreme Court, after the operation was performed and the operating surgeon was closing the incision, he requested a deeper anesthesia. The anesthetic used was ethylene gas, carbon dioxide gas, ether and oxygen. The defendant anesthetist, at the time of the request for deeper anesthesia noticed that the oxygen in the tank was being depleted. He ordered a fresh supply. It took about five minutes to connect up the new tank, and when this had been completed, the patient was dead. The nurse who assisted in the operation testified that the defendant continued to administer the anesthetic while the oxygen supply was being replenished and that the anesthetic mask was held on the patient's face by the defendant during that time. An osteopath, testifying for the plaintiffs, stated in answer to a hypothetical question that the deceased died of asphyxiation resulting from the administration of ethylene gas without oxygen. The medical testimony was in agreement that the breathing of ethylene gas without oxygen for a few minutes would probably be fatal. The defendant contended that the patient died from heart failure

and that he did not hold the mask tightly over the patient's face during the period of the change of oxygen tanks, but kept his finger under the mask, raising it slightly so that the patient could breathe. Medical experts testified for the defendant that the patient's symptoms, particularly a drop in blood pressure prior to cessation of respiration, indicated death from heart failure and that the symptoms of asphyxiation were not present.

Although the weight of expert medical opinion for the defendant, said the Supreme Court, was greater than that for the plaintiffs, there was sufficient direct evidence supporting the plaintiffs' theory of the cause of death to justify a submission of the case to the jury. In the absence of prejudicial error committed by the trial court, the jury's verdict is binding. The opinion of an expert witness, continued the court, does not become valueless by reason of the omission from a hypothetical question of some disputed facts. "The question may be framed upon any theory of the questioning party which can be deduced from the evidence, and the statement may assume any facts, within the limits of the evidence, upon which the opinion of the expert is desired. It may omit any facts not deemed by the questioner material to the inquiry." *Treadwell v Nickel* 194 Calif 243, 228 P 25.

The court, finding no prejudicial error in the record, affirmed the judgment of the superior court for the plaintiffs—*Forbis v Holzman (Calif)* 55 P (2d) 201.

- Virginia Medical Society of Staunton Oct. 13-15 Miss Agnes A Edwards 1290 East Clay St. Richmond Secretary

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

- Interstitial Pregnancy. A. E. Kanter. Chicago—p. 167.

Histopathology and Treatment of Vaginitis—Adair and Hesselstine have cured vaginal trichomoniasis and senile vaginitis with lactose (95 per cent) and citric acid (5 per cent) therapy. Focal infections have been treated simultaneously. Although recurrences have developed there have been no failures as yet. Generally, vaginal trichomoniasis and senile vaginitis respond slowly to treatment. The maximal period of treatment and observation was ten months in one instance while the minimum was two months. Some recurrence of vaginal trichomoniasis and probably some exacerbations are

due to reinfection and reinfestation from sexual partners. The principle of this type of therapy is to supply directly nutritive substances which are necessary for a normal vaginal flora. This nutritive material may be supplied indirectly as a result of hormone stimulation after the menopause. The histopathologic pictures obtained by biopsy from the vaginal wall in trichomoniasis, mycoses and senile vaginitis are not distinguishable. Biopsies from the vagina have revealed that even though the clinical appearance and smears are normal, inflammation may continue to exist in the epithelial and subepithelial layer for varying periods. The microscopic examination indicates an increased number of glycogenic granules in the epithelial cells of the treated cases, the deposition of which may be a factor in producing the beneficial effects of this treatment. The excellent results may be from the creation of conditions that favor the development of a normal vaginal flora or from factors that permit or stimulate normal epithelial growths, or a combination of the two.

Study of Placenta Praevia—Irving discusses the 308 cases of placenta praevia that were seen from 1916 to 1935, among 28,391 deliveries in the inpatient service of the Boston Lying-In Hospital. The actual delivery of these 308 patients was conducted by eighty-five visiting and resident obstetricians, the latter always under supervision. A general analysis of the various types of treatment used in the entire series shows that they may be classified as (1) expectant, consisting of simple rupture of the membranes, or normal or operative delivery at full dilatation, (2) cesarean section, (3) Braxton Hicks version, (4) the Voorhees bag, and (5) accouchement force. A study of the cases shows a decrease in maternal mortality from 11.6 to 2 per cent, and a decrease in net fetal mortality from 47 to 20.3 per cent. In clean cases in which the infant is alive, normal and of an estimated weight of more than 4 pounds, cesarean section offers about an 85 per cent chance of securing a living child, with a risk to the mother not exceeding 5 per cent. In clean cases in which the infant is dead, deformed or less than 4 pounds in estimated weight, Braxton Hicks version may be performed by the trained obstetrician at no greater risk to the mother than cesarean section. In clean cases of marginal placenta praevia, simple rupture of the membranes deserves an extended trial. It is safe for the mother and apparently less injurious to the child than has been supposed. In infected cases, cesarean section followed by hysterectomy is the operation of choice regardless of the condition of the child.

Quantitative Friedman Test in Hydatidiform Mole—Schoeneck tried to determine the minimal amounts of urine, at various stages of pregnancy, required to produce positive Friedman reactions. With such normal standards established, a quantitative Friedman test is made available. Nonpregnant does weighing at least 1,500 Gm and between 16 and 18 weeks of age were used. All animals were of the same or similar breeds and were obtained from the same source. Fractional intravenous injections of known pregnancy urines were made in dilutions of 0.025, 0.05, 0.1, 0.5, 1 and 3 cc., and so on. From two to six rabbits were used for each test. The animals were laparotomized forty-eight hours after the injections. Corpora haemorrhagica or fresh corpora lutea were the criteria for a positive reaction. In general, the smallest amounts gave positive reactions between the sixth and tenth weeks of pregnancy. Sixty-seven quantitative determinations were made on forty-one known pregnant patients. The smallest amount of urine that gave a positive reaction in normal pregnancy was 0.05 cc. The maximal amounts varied between 3 and 5 cc. The results of the quantitative test in four cases of hydatidiform mole and one of chorionepithelioma are given. A wide variation (between 0.0063 and 5 cc.) is noted in the mole cases. Two cases of hydatidiform mole showing marked hyperexcretion of the substance responsible for the reaction exhibited typical textbook specimens of hydatidiform mole, i. e., grapelike masses of vesicles whereas in the other two instances the specimens were made up principally of fibrous tissue with comparatively few vesicles. The composite results of eighty-four quantitative tests on fifty-six pregnant patients show that the group in which nausea and vomiting were absent required more urine to produce positive results than did the groups

in which these symptoms were present. The contrast is especially marked between the nausea and vomiting group and that including the pernicious vomiting cases. In the pernicious vomiting cases, as the symptoms abated, the amount of urine required to produce a positive reaction increased. While there is insufficient evidence to advance a hormone explanation of the cause of vomiting of pregnancy, the evidence seems important enough to warrant continued investigation.

Senile Vaginitis—Simpson and Mason offer evidence that, in thirty cases of senile vaginitis observed an increased intake of vitamin A, in the form of cod liver oil or halibut liver oil, proved unusually effective in producing rapid relief of the symptoms and in gross and histologic repair of the vaginal lining. They attribute these effects to the beneficial action of vitamin A in restoring to a normal healthy state the vaginal epithelium suffering from a chronic low grade deficiency of this vitamin.

Treatment of Subacromial Bursitis by Roentgen Irradiation—Lattman states that subacromial bursitis was first described by Codman in 1906. After discussing the etiology, the pathologic anatomy and the symptoms he gives a tabular report of twenty cases in which roentgen therapy was employed. As a rule, he applied 350 roentgens with the following factors: 200 kilovolts filter consisting of 0.25 mm of copper 50 cm.

distance, fields of 15 by 15 cm on the anterior or posterior side of the shoulder. The author asserts that the results obtained with this treatment justify the belief that roentgen therapy will relieve pain and restore function more rapidly than other methods of treatment. He treated many other cases with equally good results, but only in the twenty reported here has he been able to follow up the patients for a period ranging from one to five years.

Sterilization in Carcinoma of Breast—According to Smith, it is well known that there is a definite relationship between the activity of the ovary and the histology and physiology of the breast. He cites a number of cases of carcinoma of the breast in which sterilization was brought about by applying from 600 to 1,200 roentgens anteriorly and also posteriorly to the pelvis. He found that certain cases of carcinoma of the breast in young women show marked improvement after irradiation of the ovaries with a sterilizing dose of roentgen rays. Improvement may be evidenced by disappearance of metastatic nodules in the skin, shrinkage of glands showing metastatic involvement, a better blood picture, change of the osteolytic type of bone lesion to the osteosclerotic type, alleviation of pain and a subjective feeling of general good health. No conclusions can be drawn at present on any effect roentgen irradiation of the ovaries may have on the time interval of appearance of metastases after irradiation. Only one of the patients has shown more than slight menopausal symptoms. At present the author has no reason to believe that sterilization prolongs the duration of life in these patients. His observation leads him to believe, however, that the course in sterilized patients is fairly good, terminating in a relatively sudden decline whereas the course in unsterilized patients is a steady painful decline during which the patient is unable to live her usual life. Although no such comparable evidence of hormone influence has been shown to exist in other malignant conditions, experimentation in this direction deserves more attention and should be carried out. He believes that all women with carcinoma of the breast who have not reached the menopause should receive ovarian irradiation.

Roentgen Treatment of Cancer of Bladder—Ferguson reports a series of forty-eight cases of tumor of the bladder treated by divided doses of roentgen rays at long distances. He began the treatment with a technic previously used: 200 kilovolts, 0.5 mm of copper 1 mm of aluminum 70 cm target skin distance, 300 roentgens daily to each of two portals. With this technic it is possible to deliver to the pelvis from 2,000 to 2,700 roentgens through each of four portals. However this total was seldom realized in the early cases owing to rectal mucositis and rectal and bladder tenesmus. The technic was gradually changed. At present it is as follows: 200 kilovolts, Thoraeus filter (equivalent of 1.62 mm of copper) 100 cm target skin distance and 100 roentgens daily to each of two opposite portals. Four skin fields are used the remaining two being treated on alternate days. With this technic totals of from 3,000 to 4,000 roentgens per field may be easily reached, thereby delivering a total of from 12,000 to 16,000 roentgens to the four skin portals. From these factors it was estimated that a bladder tumor at the average depth of 10 cm. in the body would receive from 10 to 13 threshold erythema doses, respectively from 3,000 to 4,000 roentgens delivered to each of four skin fields provided the four beams actually converged in the bladder. In summarizing the effects obtained with this treatment, the author says that of thirty-six cases all verified by biopsy and subsequently observed cystoscopically there were twenty complete regressions, with the appearance of a new tumor in but one of these cases. In the cases in which regression was incomplete subsequent treatment was much simplified and usually consisted in fulguration and radon implantation in the base of the remaining tumor or tumors through the cystoscope. Treatment by this technic can be carried to a total of from 3,000 to 4,000 roentgens to each of four portals without marked constitutional effect and with very little local irritation to the skin bladder and rectum. The rate of primary regression reported in this series of tumors of the bladder exceeds that observed with any previous form of irradiation with which the author is familiar.

Racial Trends in Certain Surgical Diseases—Maes and McFetridge believe that the Negro has an apparent racial immunity to certain infections, chiefly of the streptococcal variety, to certain forms of inalignant growths chiefly of the superficial variety, and to biliary and urinary lithiasis. He is less likely to develop such diseases as appendicitis, cholecystitis and peptic ulcer but more apt to exhibit them in a graver form than does the white man. He is peculiarly susceptible to respiratory infections, and even in such diseases as emphysema in which the incidence is low the mortality is prone to be high. The inescapable conclusion is that as the Negro loses his immunity to the so-called acquired diseases or diseases of civilization, he tends to exhibit them in a virulent form, and that the virulence is aggravated always by his mode of life, his disregard of inaugural symptoms and his pernicious habit of self medication. The records of the Charity Hospital clearly prove that the Negro responds to certain diseases in a different fashion from the white man and usually in a more disastrous fashion. Every analysis of statistics from this institution ought to be made on the double basis of the Negro and white hospital population, for the surgeon who operates on Negroes especially for acute or grave diseases, most of the time begins his work with a very heavy handicap.

Two Stage Amputation for Diabetic Gangrene of Leg—Crossan declares that formal amputation for diabetic gangrene is fundamentally wrong. It involves, in the making of the flaps, dissection of one layer of tissue from another at the expense of some blood supply. The greatest assurance for the life of the patient can be secured by the guillotine or Einschnitt operation. This does not mean the modified flap operation, leaving the stump open, for that provides only for some drainage in case of infection; it does not exclude damage to circulation nor does it give the maximum amount of drainage. All the tissues should be cut at one level and preferably it should be done in the leg about two handbreadths below the tibial tubercle. Performed in this fashion there is little disturbance of the blood supply and small chance of gangrene, provided a tourniquet is not used. Also the stump is wide open and without recesses, with a minimum of devitalized tissue, in fact, it has everything that discourages supuration. Secondary operation will be necessary to give a serviceable stump. This the author usually does after several weeks or when bacteria counts of the wound show only two or three in a field. Between operations the wound is dressed at weekly intervals with cod liver oil until clean enough to start bacterial counts, then dressings are done every other day. The secondary operation might take any form the surgeon may choose. A Carden or even a Stokes Gritti operation may be done with safety for the removal of the foot and portions of the leg has permitted the development of a good collateral circulation. Removal of the foot and leg also provides a more rapid circuit of blood and a better nourishment of the tissues.

Thymic Death and Meteorological Environment—In view of the absence of any macroscopic and microscopic changes to account for unexpected death, and in the presence of an enlarged thymus and spleen, hyperplasia of the lymph glands

with prominent Peyer's patches, associated with hemorrhage in Peyer's patches and intestinal tract, the diagnosis of "status thymicolymphaticus" was made. This diagnosis Levinson has employed in the unexpected deaths, particularly in infants and children, when they were referred to the coroner's office, and when a necropsy presented evidence indicating thymic death. Pathologic anatomic proof for death cannot always be demonstrated. The absolute proof of the cause of death might be a functional disturbance associated with altered biochemical changes, disturbed pathologic-physiologic alteration, or constitutional variability markedly disturbed by extrinsic agents, such as physical and meteorological climates. Status thymicolymphaticus is a constitutional type. Sudden death here might occur when an unusual meteorological situation might require prompt physiologic adjustment. In view of the meteorological associations here determined the emphasis that Paltouf placed on the fact that an anatomic change is not necessarily involved in sudden death of 'status lymphaticus' finds its logical explanation in death due to a sudden chemical and endocrine upset of the type that Petersen has determined as common with meteorological changes. In a period of four years there were twenty-eight deaths in infants and children on whom a necropsy was performed and a diagnosis of status thymicolymphaticus was made. In 1932 the death certificates from the Chicago health department were investigated and indicated nineteen deaths from status lymphaticus. In order to correlate the association of the adrenal with the thymus in reference to 'sudden death, fifteen cases of Addison's disease are compared with thymic deaths for the year 1932 and the meteorological theory is supported in that death in Addison's disease also occurs when adrenal inadequacy would be manifest most acutely.

Abnormalities of Micturition Due to Neurosyphilis—Langworthy and his collaborators review bladder abnormalities characteristic of tabes dorsalis. They deal with the neurophysiology of the disturbances that are dependent on damage to the posterior sacral nerve roots. The vesical symptoms of which these patients complain are typical for this particular type of abnormality. Loss of sensation may be demonstrated in the vesical wall. Graphic records of vesical filling show a low resting intravesical pressure and a large volume. No waves of vesical contraction occur during filling. A case of vesical crises is described. Typical changes in the urethra and bladder can be seen with a cystoscope. Injury to other portions of the nervous system due to syphilis gives records of vesical filling typical of the anatomic lesion.

Relationship of Colitis and Proctitis to Lymphopathia Venerea—Goodman reports that, in a series of twenty unselected cases of proctitis and/or colitis without rectal stricture, seven gave positive Frei reactions. He describes the necroptic aspects of one of these cases. Four additional cases with rectal stricture as well as colitis were also found to show positive Frei reactions. The case histories of these eleven patients are given. Two of the patients with stricture were treated with malaria. One patient with stricture and an active amebic dysentery gave a history of draining inguinal sinuses twenty-four years before. One patient with rectal stricture showed an apparent spread of the infection to pelvic viscera, colon, kidney and colostomy opening. The frequency of secondary anemia in patients with rectal and colonic lesions of lymphopathia venerea is pointed out. The evidence for the presence

of the virus in the bowel lesions is reviewed. The necessity for considering lymphopathia venerea in the differential diagnosis of chronic nonspecific ulcerative colitis is emphasized.

Protective Action of Sulfhydryl Against Induced Carcinogenesis—The carcinogenic agent 1,2,5,6-di-benzanthracene and a substance containing the proliferation-stimulating group sulfhydryl parathuocresol, were applied by Reimann and Hall to the skin of mice in various combinations. The incidence of cutaneous tumor was reduced by the action of sulfhydryl. Irritation played no part in the protection. Evidence is adduced to support the following propositions: Stimulation of the rate of cell proliferation alone does not lead to neoplasia, carcinogenesis is caused by damage to the potencies of differentiation and organization, this damage must be transmitted by a cell capable of division or by somatic mutation, when a cell reaches a certain degree of differentiation it can no longer divide and the damage to the potencies of differentiation and organization must occur before potency is determined, at least in cutaneous cells. The previously enunciated definition of tumor is strengthened.

Caisson Disease—Lichtenstein and Zeitlin point out that paraplegia is only one of the signs observed in men with caisson disease on their return to normal atmospheric pressure. Among the many names used to designate this condition ('dyer's palsy,' 'bends,' 'compressed air illness' and 'caisson disease') the term 'aeropathy,' suggested by Erdman, is most appropriate, for it signifies the underlying pathogenic factor of the various symptoms incurred in caisson work and in occupations associated with similar hazards. Pleomorphic as the symptoms of caisson disease are, paraplegia is the most striking. Most of the contributions to the pathology of caisson disease in general and to that of the spinal cord involvement in particular have pertained to cases in which the disease was relatively acute. This contribution deals with the changes in the spinal cord of a man who had had the disease for twenty-five years. The authors give the clinical history of this patient and describe the results of the necropsy. The changes outlined can be summed up as ascending and descending degeneration of the spinal cord secondary to a severe destructive lesion of its thoracic portion. The cause of the central nerve lesions in caisson disease is usually considered to be embolism of minute blood vessels which causes degeneration of all the constituent nerve elements. The authors say that Bassoe classified cases of caisson disease in its late manifestations into three groups: (1) cases in which the spinal symptoms predominate so-called caisson myelitis, (2) cases in which there is permanent involvement of the joints and (3) cases in which there is permanent involvement of the ears. They admit that the common occurrence of spastic paraplegia in caisson disease can be explained by the changes in the spinal cord but they stress that these changes certainly were not inflammatory, in the nature of a myelitis but degenerative. In answer to the question as to what causes this degeneration they give their version of the pathogenesis of caisson disease. They state that in chronic combined degeneration of the cord due to aeropathy the thoracic portion of the spinal cord is the site of prevalent involvement and of this the white matter is much more affected than the gray. The old scars resulting from the embolic

occlusion of the capillary blood vessels are exclusively ectodermal and characterized pathologically as anisomorphous gliosis. This condition is best differentiated histologically from multiple sclerosis by detailed study of the areas adjacent to the scars and of those of normal remote regions.

Tumors on Spinal Cord—Jones and Naffziger report that, regardless of the location of the tumor, pain was the most common and usually the initial symptom in their series of fifty-nine cases. It often was present for years before neurologic signs appeared. The pain often simulated that of other disorders, and the patients complained of rheumatism, neuritis, sciatica, lumbago, sacro-iliac strain and abdominal symptoms. In the early stages the pain was invariably localized. In most instances it later developed into a combination of localized and radiating pain. The so-called hour-glass type of tumors have an intraspinal portion connected by a small neck with an extra spinal enlargement. The connection occurred most frequently through an intervertebral foramen but occasionally through an interlaminar space. It is generally accepted that hour-glass tumors are rare, yet there were fifteen such cases in this series. The most important complaint in this group was localized pain. Palpation of the extraspinal portion of the tumor was possible in the cervical region and occasionally in the thoracic and lumbar regions. Roentgenograms of the spine proved extremely valuable. The differential diagnosis between intramedullary tumors and extramedullary intradural tumors is difficult. However, in the extramedullary tumors there was usually a clear-cut history of gradually increasing compression of the spinal cord. In these cases the sensory level was almost always sharply demarcated and tended to be more pronounced in the distal part of the lower extremities than in the higher segments corresponding to the level of the lesion. In the intramedullary tumors the reverse was true, that is, the maximum sensory loss corresponded to the segments of the cord immediately involved while the sensory alteration in the distal parts of the extremities was not so marked. In addition, in an intramedullary growth sensation tended to fade off above the level of the tumor in a more or less indefinite fashion. Involvement of the conus medullaris by an intramedullary or an extramedullary tumor led, in all instances, to early involvement of the sphincters and varying degrees of impotence. Of the fourteen tumors occurring in the region of the cauda equina four pathologic types deserve mention: (1) neurofibroma, (2) dislocated nucleus pulposus (chordoma), (3) epidermoid, and (4) large soft dural endothelioma. The simplest differential diagnostic test is compression of the jugular and cervical veins. The frequency with which tumors of the conus medullaris and cauda equina simulate orthopedic disorders warrants the recommendation that this test be employed in a routine way in orthopedic examinations in which localized or radicular pain is present. The patient is placed in a comfortable position and when free from pain compression of the cervical veins is made as in the Queckenstedt test. As the intracranial and intraspinal pressure above the level of the block is raised the characteristic pain may be produced if the tumor is capable of being displaced sufficiently to cause traction on or irritation of a nerve root. Although most commonly the pain is reproduced by compression of the jugular and other cervical veins, in certain instances (depending presumably on the direction in which the tumor

dislocates most readily) such pain may be experienced only on sudden release of the jugular compression. Though radicular pain is commoner in cases of tumor of the cauda equina, the value of the test is by no means limited to tumors of this region but has proved of differential value in lesions of various pathologic types involving the cervical and thoracic portions of the spinal cord.

Ruptured Appendix in Children—Brumgartner maintains that the high incidence of 55 per cent of perforated appendices in children is due almost entirely to delay. He stresses that the medical profession should repeatedly remind the public of the possible danger of appendicitis in any ordinary so called stomach ache in children and persistently warn against the promiscuous use of laxatives before appendicitis has been definitely ruled out. The frequent association of nasal colds, sore throats and middle ear infections is particularly misleading, and parents as well as physicians must realize that their presence with an abdominal pain does not necessarily rule out appendicitis. The use of the continuous dextrose drip in conjunction with the indwelling nasal catheter has been a distinct advance in the postoperative care of these children not only in that it provides greater comfort but also in that normal body chemistry is restored and toxins relieved in the quickest possible manner.

Treatment of the Parkinsonian Syndrome—Marshall endeavored to treat nine cases of postencephalitic sequels with psychotherapy, relaxation and reeducation, with the cooperation of physical and occupational therapy. Psychotherapy was the chief agent in the treatment of these cases. Relaxation and reeducation were very important adjuncts. The realization that patients with the parkinsonian syndrome experience regarding their inability to perform the most simple associated movements throws them into mental conflicts. The retroversion from a highly integrated individual into one of the merest basic functioning is the basis of the emotional upset seen in the disease. In constructing the chain of events that lead to this clinical picture, it is of primary importance to recognize that the pathologic picture is quite a definite entity. Sections

of the brain show damage in the subcortical areas. These areas have to do with associated movements. The deprivation of the associated movements in a patient is the basis for the psychoneurotic symptoms, which Haskovec thinks are caused by a subcortical, morbid process. These symptoms are an outgrowth of the inability to coordinate and are on the same basis as a frustration, exemplified by speech defects and behavior problems. Prior to his disease the patient has held a definite position in his own society. However, when he finds himself an invalid, from the point of view of having lost his ability to perform the most simple actions of life, he receives a tremendous psychic shock. The patient realizes his predicament and must cope with these difficulties in some manner. He tries to cover up these defects. This seems to be the basis for the entrance of the so called psychoneurotic symptoms which these patients show. The patient believes himself to be a cripple, is told that he probably will always be so by the profession and consequently adapts a fitting psychology by beginning to believe earnestly that he cannot overcome his handicaps. Nearly all of the author's patients agreed that they have experienced such a mental attitude. The first step was to establish a "rapport" with the patient. The next step was to effect this by relaxing the contracted parts. Then the process of reeducation or conditioning was tried, that is attempting to supply new habits for the old ones. The psychic factor was of vast importance here, as the patients at first experienced a feeling that they could not execute the exercises because of their physical incapacities. Continued reassurance and effort on the part of the attendant, went far in bringing about success in most cases. It was well to convince the patient that the treatment was not a physical impossibility, accomplished by presenting an improved patient to him, at the same time having the former relate how he was prior to treatment. This greatly helped to encourage the patient undergoing treatment and certainly aided in building up his morale. It assisted in bringing about enthusiasm. The patients responded to the method of treatment in such a manner as to warrant further observation and study by other clinicians before any definite statement of encouragement can be given. The author believes that the mental catharsis which most of the patients experienced was responsible for the improvement obtained.

Simple Method of Oxygen Analysis—Riseman and Lesnick devised an apparatus to satisfy the need for an instrument which would be accurate, inexpensive and simple enough to operate so that it could be used efficiently without any previous instruction or experience. The simplicity of operation is attested by the fact that nurses and laymen without supervision and with no previous experience with oxygen analysis have experienced no difficulty in using the apparatus for the first time. In principle the method consists of absorbing the oxygen from a known volume of gas and determining the residual volume. The oxygen is absorbed by means of copper gauze and an ammoniacal solution. Simplicity of operation is attained by three devices, which result in automatic measuring of the volumes of the sample and the residual gas and in simplified operation of a three way valve. The method yields results that are accurate within 2 per cent.

Treatment of Chronic Heart Disease by Total Thyroidectomy—Riseman says that in two and a half years about 100 patients have been treated by this method at the Beth Israel Hospital in Boston. The author presents the results obtained. He says that the operation confers benefit on a group of cardiac patients who have not been helped by any other method known at present. If the patients are carefully chosen with respect to preoperative basal metabolism and progress of

their disease, a satisfactory high percentage of good results can be expected. To keep mortality down and insure a maximum number of good results, the patients must be carefully prepared for operation and the operative technic must be faultless. Finally, the postoperative care of these patients during the months and years they have to live is an extremely important matter and requires careful supervision.

Stokes-Adams Syndrome Following Influenza—Mares says that the attending physician should watch for signs of cardiac damage in influenza. That the influenza is running a mild course is no guaranty against involvement of the heart. The heart complications are usually of late appearance after the fever has run its course and often after convalescence is well advanced. They may not be recognized till they appear as late sequels, months after the influenza. Furthermore it is probable that many cases of myocardial disease are attributable to influenza dating back for a period of years just as is the case with rheumatic fever. Complete heart block is a relatively rare complication of influenza, and the Stokes-Adams syndrome is still more exceptional. But a slow pulse has been noted as a fairly frequent accompaniment of influenzal infection for which various explanations have been advanced: toxic inhibition of the impulse-forming activity of the sinus node, vagal excitation, dromotropic disturbances and causes outside the heart. The fact that the pulse disturbances sometimes appear long after the illness shows that they must have some other basis than the physical and psychic prostration that are such well known features of convalescence from influenza. The cases occurring during convalescence would seem to find adequate explanation in toxic injury either to the vagus with stimulation of its inhibitory influence on the heart action or to the conduction pathway in the myocardium with interruption of impulses from the auricle to the ventricle. In either case the blood supply to the brain would be temporarily cut off with syncope as the natural consequence. The author reports the history of a man aged 29 whom he saw during an influenza epidemic and who complained of dizzy spells. Following the third attack he was brought to the hospital. During the next twenty-four hours he had eight paroxysms which gradually decreased in severity. He was given atropine one one hundredth grain (0.00065 Gm) every four hours along with barium chloride two-thirds grain (0.04 Gm) every six hours.

After thirty six hours the pulse rate gradually increased and the atropine was omitted. During his hospitalization, two thirds grain doses of barium chloride were given four times a day. On his discharge, this was continued in two thirds grain doses three times daily, and at the end of the fourth week his pulse remained at 70. The barium chloride was discontinued at this time. Two weeks later the pulse rate was maintained at sixty-eight, with no recurrent symptoms.

Initial Cold Water Treatment for Burns—When Rose sees the patient soon after the accident, he applies cold water to the burned tissue after as much clothing as possible has been removed. Ordinary tap water is used. In the case of small burned areas or a part of a single extremity, cold wet dressings are applied or the parts submerged in basins containing cold water. In the case of extensive burns, the patients are placed in a tub. The immediate results are favorable. Patients with severe pain are relieved within a few seconds without the use of an opiate. Patients in early shock often respond promptly with no other measures, the weak and feeble pulse becoming slower and stronger, the blood pressure rising and the patient's color resuming a normal appearance. A burn involving one half of the body surface has usually been regarded as fatal, and the fatal outcome is the result primarily of the shock. "The primary phase" of shock is due to the pain of the direct nerve injury, with its resultant reflex vasodilatation. The more important type of shock, however, is the so-called secondary shock which is due to loss of fluids from the circulating blood. If some time has elapsed before the patient is first seen, so that the state of shock is rather far advanced, other shock therapy is started in addition to the cool water. Fluids by mouth are given immediately and a transfusion of blood is started while the patient is still in the tub. If a donor is not available, intravenous acaera is used. For the next two hours this treatment is continued. During this time the water is gradually warmed, as rapidly as the pain sensations of the patient will permit. The temperature of the water at first is between 60 and 70 F. At the beginning of the third hour it is about 98 F. At this time one-fourth grain (0.016 Gm.) of morphine is usually given, preparatory to the mild debridement to follow. About half an hour later remaining pieces of clothing are removed, dead tissue and dirt are wiped away with gauze and blebs are opened. If much dirt and grease are present the body is scrubbed from head to foot with sterile soap and water. After the burned areas and body are clean, the patient is rinsed with sterile water and dried with warm air from an ordinary hair drier. The patient is then placed on a sterile sheet on the bed and is ready for Bettman's tannic acid and silver nitrate treatment or the ferric chloride coagulation method described by Coan.

Postdelivery Deaths Caused by Embolism—Hemmings found the total incidence of postdelivery embolism in a series of 80136 births to be 0.04 per cent. Postdelivery embolism presented an incidence of 7.8 per cent of the total deaths and 14.5 per cent of the delivery deaths. The incidence of postdelivery embolism was more than three times greater when operative intervention was used than in normal deliveries. Cesarean section rated second in incidence of all operative procedures. The mortality rate was highest between the ages of 26 and 30 years. Adequate antepartum care did not prevent

embolism in 78 per cent of the series. The average duration of labor in all cases was sixteen and a half hours. The most frequent causative factors were hemorrhage, trauma, infection and venous stasis. Available blood counts generally revealed a well marked secondary anemia. Symptoms of phlebitis were present in only 24.3 per cent of the patients. The medication used had no direct bearing on the causation of embolism. In order to improve the understanding and knowledge of postdelivery thrombosis and embolism, necropsies performed by obstetrically minded pathologists should be insisted on.

Acute Gastro-Intestinal Allergy—Dutton thinks that failure to consider allergy in differential diagnosis is particularly common in the field of abdominal surgery. In studies that he conducted in order to determine how innocent appearing appendices can cause symptoms sufficiently grave to bring patients to the operating table, he detected two factors, which he at first did not appreciate. They were edema and eosinophilic infiltration. However, the significance of eosinophilia in allergic reactions in other tissues became established about this time.

Dr. Robert H. H. H. H.

A. E. A. Medical College

The author studied this field, but it became at once apparent that allergy alone would not explain all the facts observed. Many appendixes with an eosinophilic infiltration also presented definite evidence of infection. When the histories of these patients were studied, the conception of the interrelationship of allergy and infection agreed. It is the author's present belief that either infection or an allergic reaction may imitate symptoms referable to the appendix or other tissues and that the allergic reaction is more frequently the first. It is also his conviction that many appendixes are removed before infection develops. He believes that proper attention to the allergic phase might bring relief to many patients without operations. Many patients are not relieved by surgery. He lists some of the symptoms that have been proved to be definitely caused by allergic reactions to foods: canker sore, coated tongue, heavy breath, distention, belching, epigastric heaviness, sour stomach, burning, pyrosis, nausea, vomiting, diarrhea, mucous colitis, constipation, "gas in the bowels," pruritus ani, pain and soreness in the epigastrium, colonic soreness and the ulcer type of pain. General symptoms are toxicity, weakness, irritability, nervousness, mental dulness and depression, general aching, fever and so on. From this list it is apparent that certain abdominal symptoms might easily be interpreted as acute or chronic appendicitis, ulcer, cholecystitis, cholelithiasis, renal colic or even, in extreme cases, obstruction. Of 150 cases in which these symptoms had appeared, operations had been performed in forty-seven without permanent relief. A diagnosis depends on a careful history, including the allergic history, and a careful physical examination and blood study, weight being given to those slight variations caused by allergy. The treatment is symptomatic—epinephrine, ephedrine and opiates, fundamental—diet along allergic lines, and surgical intervention if necessary.

 Radiation Therapy of Lobar Pneumonia. E. V. Powell, Temple—p. 237

Radiation Therapy of Lobar Pneumonia—Powell reports a series of forty-seven cases of lobar pneumonia in which, in addition to the other usual methods of treatment, roentgen therapy has been given. In this series only one patient died, whereas of seventy-six patients admitted immediately preceding and during the early part of this series who received in general the same treatment except that they were not irradiated, twenty-two died. Ten of the case histories are abstracted to illustrate individual reactions. Perhaps the most impressive thing in observing the patient is the marked relief of discomfort and the promptness with which a number of the patients developed crises. Treatment of bronchopneumonia is discussed very briefly. Conclusions are hardly warranted until a larger number of cases have been observed, however, the author thinks that a mortality of less than 25 per cent in lobar pneumonia and only 14 per cent in all types of pneumonia in which roentgen therapy was administered during the past forty months warrants continued use of the method unless some practical contraindication can be demonstrated.

Psychologic Factors in Asthma—Gillespie believes that asthma furnishes a striking text of what needs to be emphasized in the education of medical students: that the body and the mind are one, or at least that their interaction is so close that no examination of a patient should neglect some consideration of what is going on in his mind. There is evidence that a stock in which asthma occurs is often also one in which there is a high incidence of psychoneurotic manifestations as if the asthma and the psychoneurotic constitution were closely allied. The function of breathing is very much subject to emotional influences in everybody. Numerous studies of respiration curves have demonstrated objectively the close relationship between emotional stimuli, or states of mind, and the respiratory function. The physiologic mechanism of asthmatic attacks seems to involve among other things a disturbance in what is usually called the vagosympathetic "balance," which is very much influenced by emotional states. Every emotion tends to be propagated like a wave of physiologic disturbance through the vagal and sympathetic system to the viscera. If there is already existing some disturbance of the vagosympathetic, clearly the emotional disturbance will have unusual effects, and asthma may be one of them. Psychologic stimuli can be equipotent with physical ones in producing signs and symptoms of physical disease. An idea may become the effective stimulus which elicits the asthmatic response just as much as pollen or horsehair. Not only may psychologic factors in the shape of emotions or ideas elicit individual attacks, but they may act in continuing fashion to produce a state of tension which every now and then may reach explosion point and express itself in an asthmatic paroxysm. The choice of asthma as the special mode of expression of mental unrest, whether the latter takes a psychoneurotic form or not, depends (1) on constitution, accident, preexisting fear of lung disease, preexisting disease of the lungs, a conception of breathlessness or an imitation of asthmatic attacks which the patient has witnessed, or something akin to them. This can apparently be a factor in determining the expression of the psychoneurosis in this particular way. The most obvious type of relationship between asthma and psychologic conditions is the frequency with which asthmatic patients exhibit what would be called a neurotic type of personality long before an asthmatic attack began.

Treatment of Disseminated Sclerosis as Deficiency Disease—In treating fifty cases of disseminated sclerosis, Goodall and Slater advised half a pound of liver two or three times a week and prescribed in addition a diet of eggs, milk, fresh vegetables and fruit. The cereals were greatly restricted or cut out altogether. Potatoes and tomatoes are efficient substitutes. No other restriction of diet was made. In other directions, patients are encouraged to carry on their ordinary avocation as far as possible. None of the advanced cases in the series had reached the stage of contractures and bed sores. A feature of most cases is the early change in the

degree or rate of nystagmus, with its frequent entire disappearance. There has been only one relapse in a patient who has begun to improve and has kept to the diet. Owing to the different classes of case and the differences in observation period, no general statement of numbers improved or worse is made, but the nine patients with disseminated sclerosis of a duration less than one year are at work and six of them have been observed from two to five years. Of the nine with a duration of from one to two years, six are known to be working and all had improved when last seen.

*Study of Incidence of Cancer of Lung and Larynx. A. M. Kennaway and E. L. Kennaway—p. 236

Nasal Diphtheria Carriers.—Rudolf and Ashby studied sixty-two adult male carriers of morphologic *Bacillus diphtheriae* occurring in an institution. No cases of clinical diphtheria developed, although tests demonstrated that many of the cultures were virulent to guinea-pigs. Others were avirulent. Nasal swabs were collected at irregular intervals and were continued until three successive negative specimens had been obtained from each patient. The patients were isolated and treated with gargles of physiologic solution of sodium chloride and the sniffing of solution of sodium chloride up the nose three times a day. The investigation is based on the hypothesis of a constant probability of obtaining a positive swab under these conditions of treatment. With this treatment the majority of the patients were carriers for periods of less than nine days. Two successive negative swabs were followed by positive results in twenty-two cases. In order to recognize 99 per cent of the carriers in a population receiving treatment with physiologic solution of sodium chloride, five swabs are required from each person examined.

Incidence of Cancer of Lung and Larynx.—The Kennaways examined the 18,280 death certificates for cancer of the lung and of the larynx in males from England and Wales for the years 1921 to 1932 inclusive. Necropsies have been made in about 28 per cent of the cases of cancer of the lung and 9 per cent of the cases of cancer of the larynx. The agricultural and coal mining industries show a low incidence of cancer of the lung and of the larynx. The factors that lead to silicosis appear not to be very active in producing cancer of the lung or larynx, but in metal grinders the incidence of cancer of the lung is two and one fourth times that in the general population. A group of open air occupations in which there is exposure to the dust of roads, have rather high ratios for cancer of the lung and of the larynx, with the exception that motor drivers have a normal liability to cancer of the larynx. No cases of cancer of the lung in asbestos workers have been found among the certificates considered. Workers exposed to coal gas and tar, and those engaged in the preparation and sale of tobacco, tend to show an increased prevalence of cancer of the lung. Occupations concerned with the supply of alcohol have a high incidence of cancer of the larynx. The greater incidence of cancer of the lung in men than in women is discussed. The recent rate of increase of cancer of the lung in men is found to be not much greater than that in women, when these increases are reckoned in percentages. The increase in recorded cases of cancer of the lung may be due to an actual increase, improvement in diagnosis, fashion in diagnosis or any combination of these factors. The number of deaths attributed to cancer of the prostate appears to have reached a steady level. No special occupations have been found to which the increase

in the total of cases of cancer of the lung can be attributed, rural workers show an increase which is not much less than that in the general population. No evidence has been found that tarring of roads has affected the incidence of cancer of the lung in the general population. Such data as are available suggest that coal tar in the atmosphere, whether derived from roads, domestic chimneys or any other source, does not readily give rise to cancer of the lung. Cotton-mule spinners show an especially small liability to cancer of the lung, although they inhale air sprayed with an oil which produces cancer of the skin. Improvements in diagnosis must have led to the detection of a larger proportion of the existing cases of cancer of the lung.

Acclimatization to Atmospheres with Low Carbon Monoxide.—Killick attempted to produce acclimatization in the human subject by repeated exposure to atmospheres containing low concentrations of carbon monoxide and by repeated inhalations of carbon monoxide from a closed respiratory circuit. Clear evidence of a considerable degree of acclimatization was obtained in that symptoms of poisoning lessened during successive exposures to the same concentration of carbon monoxide and the relation between the concentration of carbon monoxide breathed and the degree of saturation of the blood changed with repeated exposures. Acclimatization was not accompanied by changes in the red cell count or in the hemoglobin content of the blood. The data obtained were insufficient to justify a statement as to changes in blood volume. The partition constant between oxygen and carbon monoxide of whole blood outside the body remained unaltered as acclimatization developed. The state of acclimatization produced experimentally lasted from thirteen to eighteen months, diminishing gradually in degree until the subject returned to the nonacclimatized state after eighteen months. The two possible types of explanation for the phenomena of acclimatization are (1) a selective activity of the alveolar membrane producing either a secretion of oxygen from the alveoli into the blood or an excretion of carbon monoxide from the blood into the alveoli, (2) removal of carbon monoxide from the blood by oxidative or other processes in the tissues.

Weight of Thyroid Gland and Atherosclerosis—Although his material is not extensive, it is evident to Dungal that the Icelandic population has an unusually small thyroid and an unusually low rate of atherosclerosis of the aorta. Atherosclerosis of other arteries is also relatively rare. The question arises whether there is a causative relationship between the small thyroid (14.9 Gm for males and 11.3 Gm for females) and the low rate of sclerosis. Experimentally atherosclerosis can be produced, in rabbits, by injection of epinephrine (Josue) and by feeding viosterol. Liebig administered a diiodide of castor oil stearate having an iodine content of 116 per cent to rabbits during the feeding with cholesterol and thereby prevented or diminished atheromatosis in the aorta and the liver. Binet has shown that potassium iodide and albumin iodine have the same effect. Murata has shown that atheromatosis may be prevented in rabbits by feeding a thyroid substance. On the other hand, Pusch has shown that arteriosclerosis is four times as frequent with goiters as with nongoitrous glands. Probably the explanation for these conditions in Iceland is the abundance of iodine in the food, particularly the fish, which is consumed in relatively great amounts, but partly also by the iodine in air and soil, which probably is great. The Icelandic people range high in physical and mental powers. The question arises whether the normal weight of the thyroid is not lower than that generally accepted, and whether a low degree of iodine deficiency is not more widespread than it is thought to be.

O Agglutinins for *Bacillus Proteus* XK—Mathew says that, in recent papers on the endemic typhus of the eastern coastal areas of North Queensland by Langan and Mathew and Unwin, positive agglutination reactions with the Kingsbury strain of *Bacillus proteus* X were quoted in confirmation of the diagnosis. In the earlier tests recorded in these papers only living suspensions of *Bacillus proteus* X19 and *Bacillus proteus* X Kingsbury were used, later check tests were made with heated suspensions. The author succeeded in checking the tests further with suspensions recommended by Felix and in demonstrating that the agglutinations in these and subsequent cases are of the O type. He lists the suspensions used in the tests and describes the preparation of the suspensions, the methods of testing and the results of the agglutination tests. In summarizing his observations he states that O agglutinins for the Kingsbury strain of *Bacillus proteus* X are shown to be present in high titer in cases of one of the classes of endemic typhus in the eastern coastal area of North Queensland. It is also shown that both O and H agglutinins for the X19, X2 and XL strains of *Bacillus proteus* are not present in significant amounts.

Blood Transfusion in Treatment of Colitis—Ryss and his co-workers report forty cases of enterocolitis and colitis in which treatment was administered by means of transfusion of blood. Nineteen of the patients were treated with homogenous blood, nineteen by heterogenous and ten by combinations of the two. As heterogenous blood the citrated arterial blood of the dog was introduced intravenously in doses of 5, 10 and 12 cc at intervals of from eight to ten days. Three injections usually were sufficient for obtaining the desired effect. As homogenous blood from 250 to 300 cc. of fresh citrated or preserved blood of the same grouping was introduced at intervals of from eight to ten days. The patients, in good general health up to the age of 45 and with an approximately normal blood picture, could be treated with the heterogenous blood. In all, 126 heterogenous and fifty-nine homogenous transfusions were given. The heterogenous transfusions produced more frequent and more intense reactions, the local manifestations lasting from a few hours to several days. There was some reaction in 71.4 per cent of those receiving heterogenous and in 49.7 per cent of those receiving homogenous blood. From the clinical standpoint a marked improvement of the subjective phenomena associated with rapid increase in weight, increased erythropoiesis and improved susceptibility to specific therapy were noted. Improvements from homogenous transfusions occurred in 94.8 per cent and in the heterogenous transfusions in 90.9 per cent. When the combined method was used some improvement was noted in all patients. As a result of these studies the authors believe that depending on the status of the patient one or both of these methods of transfusion is an important therapeutic measure in the treatment of diseases of this group.

Diagnosis of Hodgkin's Disease—Because of the frequent difficulty encountered in performing biopsies in the early stages of Hodgkin's disease, Emile-Weill and his associates decided to attempt lymph node puncture. They were able to verify their observations of the accuracy of this method on twenty patients controlled by biopsy. In each case the results of the puncture coincided accurately with that of the adenectomy. The principal diagnostic criteria observed in the slides made from these punctures were endothelial elements and authentic giant cells of Sternberg. They believe that the latter elements are pathognomonic of malignant lymphogranulomatosis and that a method of lymph node puncture can be satisfactorily substituted for the more arduous and less practical biopsy.

Reflex Traumatic Contractures and Paralysis—Froment states that, following traumatism to the limbs, paralysis paresis and physiopathic contractures are frequently observed. These lesions are usually not, he believes, of a hysterical or psychopathic nature. They often develop above the traumatized area and are frequently accompanied by undeniable evidence of physiologic disturbances such as disorders of vasomotor and thermal nature, sweat gland alterations, osteoporosis, hypotonia and lowered or increased electrical excitability. The mechanism of such syndromes, which were thoroughly studied during the war, has served as the subject for interminable controversy. Thanks to experimental physiology it is becoming recognized that these symptoms are the result of a true pathologic reflex involving the sympathetic system. After studying the vasomotor reflexes of the injured limb and of the symmetrical limb of the opposite side and their reactions to diverse thermic factors, as well as the comparative study of the tendon reflexes and motor reactions in the course of chloroform narcosis, he has come to the conclusion that these are frankly disorders of the sympathetic and of the medullary centers of the injured limb. It is certainly not safe to forget the possibility of association with hysterical reactions which may involve the same region, but existence of traumatic physiopathologic syndromes is also incontestable. These lesions are, however, singularly resistant to treatment while remaining for long periods susceptible to exacerbation.

*Acute Generalized Gonococcal Peritonitis Excluding Ruptures of Pyosalpinx R Leclère—p 733

Gonococcal Peritonitis—Leclère believes that acute generalized gonococcal peritonitis without rupture of the tubes forms a definite clinical picture. The gonococcus which localizes by predilection in the pelvis can invade the general peritoneum and thus give the symptomatology of generalized peritonitis. The lesions produced are the same as those which one finds in acute inflammations of the peritoneum of other origin. The diagnosis of this form of peritonitis is difficult and often surgical intervention alone after a bacteriologic examination of the pus can yield a definite diagnosis. The fear of allowing a peritonitis of other origin to pass without operation calls for surgical treatment. In the majority of cases simple drainage without salpingectomy is sufficient to cause the cure without interfering with the genital future of those operated on. Sometimes the abdomen can be closed without drainage, especially if bacteriologic examination made at the time reveals the presence of gonococci in the pus. It is only in exceptional cases that it is necessary to perform salpingectomy and subtotal hysterectomy is definitely contraindicated. Total hysterectomy, furthermore, is wholly unindicated.

Animal Carbon by Intravenous Route R Démarez—p 1037

Nervous Syndromes in Esophageal Cancer—According to Loeper and his co workers, a review of the anatomic relations of various portions of the esophagus with the adjacent nerve elements reveals the fact that depending on the situation of the cancer numerous nerve pathways can be affected. With the preliminary knowledge that cancer of the esophagus involves the cervical region in 18 per cent, the bronchial region in 36 per

cent and the diaphragmatic region in from 46 to 48 per cent, it becomes clear that nervous complications can be diverse, depending on the localization. Excessive salivation in the course of cancer of the esophagus must be considered a sign of involvement of the nervous system. When this symptom is analyzed more closely, it becomes in reality a symptom of irritation of the vagus. The second important nervous phenomenon is pain. Pain may be preceded by disorders of swallowing or may be localized or carried elsewhere by nerves that are involved. Disorders of phonation, especially dysphonia and aphonia, are frequently seen and seem to be due to involvement of the recurrent nerve especially the left. Dyspnea is not rare and can take on a suffocating character. Anginal symptoms sometimes occur. Special study of the nerve symptoms which may arise from esophageal cancer therefore reveals the fact that the complications may be numerous and widespread because of the close anatomic relations of the esophagus to numerous nerve trunks.

Death Following Injection of Animal Carbon.—Demarez takes issue with the opinion which has been expressed that animal carbon is more effective the more closely it approaches the colloidal form. In using animal carbon in which the particles were present in a 2 per cent suspension and were for the most part less than 5 microns in diameter, he made an injection in a woman aged 34 for postpartum sepsis. Death occurred suddenly. Examination revealed that true capillary embolism had occurred and was probably the immediate cause of death. On study of the various carbon preparations, he found that those of small diameter showed a tendency to flocculate and that in all probability this flocculation in the arterioles was the cause of the accident. It is to be concluded therefore that, while the author still believes in the effectiveness of animal carbon, a suspension should not be used in which the particles are less than 5 microns in diameter, but that above this diameter the procedure is entirely harmless.

Progress of Hematology in Last Ten Years J Itelson and M Kocen—p 602

Bone Marrow Biopsies—After discussing the various technics previously employed in bone marrow biopsies Karavanoff describes the method which he used. The suprasternal soft tissues instead of being dissected are pierced by means of a special small trocar. Through this the perforating trepan is introduced. After the sternum is thus perforated, the marrow can be removed by means of a small curet or aspirated with a needle. The usual antiseptic methods are employed. Local anesthesia is given as far as the periosteum by means of procaine hydrochloride and epinephrine infiltration, and the puncture is made after anesthesia is complete. As soon as the spongy portion is reached a definite decrease in resistance is noted in the perforation. The trepan can then be removed and a small curet introduced through the perforated canal. After removal of marrow the tube of the trocar is withdrawn and tamponing is performed to arrest hemorrhage. A small piece of collodion soaked cotton can be placed on the skin over the puncture mark. They believe that this method has some advantages, especially in that it is not dangerous. It is simple and safe in all cases and allows a sufficient quantity of marrow to be removed. The possibility of infection is reduced to a minimum and the ease of obtaining a second specimen is considerably increased. In view of the marked advantages of obtaining such material in a large number of diseases, the authors think that this simple method is a considerable improvement.

Antiplatelet Serum in Hemophilic and Normal Subjects—Because of the part played by platelets in blood coagulation, Tocantins attempted the injection of antiplatelet serum

into three hemophilic subjects and one normal person. The general plan consisted in studying the numerical changes of the erythrocytes and platelets and the coagulation time and the bleeding time at various intervals after the injection of serum. No other treatment was given to the patients during the period of observation. The withdrawal of blood was made at least two and a half hours after a meal. The platelet counts were performed according to the Rees and Ecker method. The normal antiplatelet serum and the hemophilic antiplatelet serum were prepared in rabbits by five injections of platelets isolated from 30 cc. of the blood of normal and of hemophilic persons. The term fresh serum was used for that obtained from normal man two or three hours after withdrawal. The serums were always administered by the intradermal route. As a result of their observations on the three hemophilic and one normal persons, they found that there was an increase practically to normal of the coagulability of the hemophilic blood but that it did not last long, perhaps because the products of the destruction of the platelets had disappeared rapidly from the circulation or had been neutralized. The phase of normal coagulability apparently began between three and five hours after the injection and lasted for about twelve to twenty-four hours. The phase of normal coagulation was not accompanied by a rapid or immediate arrest of hemorrhage in two patients who received the serum. The local application of the serum was without appreciable effect. The direct addition of normal antiplatelet serum and hemophilic antiplatelet serum to hemophilic blood in vitro was followed by a decrease in the coagulation time of about 84 per cent while when normal antiplatelet serum was mixed with normal blood there was a reduction of 18.5 per cent in the coagulation time. It is difficult to judge of the effectiveness of the serum as a therapeutic agent, since the spontaneous cessation of hemorrhage is a phenomenon often observed in these patients.

Action of Lung on Oxalic Acid in Blood. A. Chierici—p. 501

Metabolism of Carbohydrates in Splenomegaly.—Romeo made determinations of glycemia in fourteen persons with chronic malarial splenomegaly but without fever. The determinations were made before and after administration of 100 Gm. of dextrose by mouth. The author concludes by saying that chronic malarial splenomegaly is associated with hypoglycemia that does not change or slightly changes by administration of dextrose. The hypertrophic spleen has an action on the metabolism of carbohydrates, as proved by the presence of hypoglycemia and the lack of reaction or slight reaction of the glycemia curve after administration of dextrose to the patient which action is due to the presence in the blood of a hormone having glycolytic properties secreted by the spleen, but still unknown. An intravenous injection of 5 cc. of pure spleen extract given to normal persons with normal fasting glycemia caused a slight increase of glycemia in all cases.

Glycemia Following Administration of Bile Derivatives.—Molino and Patrono made determinations of glycemia before and after administration of certain derivatives of human bile in normal persons and in patients suffering from diabetes mellitus. Both normal persons and diabetic patients were placed in three groups: those who were given an intravenous injection of 10 cc. of a 20 per cent sodium dehydrocholate solution, those who were given 2 Gm. of dehydrocholic acid by mouth and those who were given a hypodermic injection of 4 cc. of a 2 per cent sodium cholate solution. The determinations were made on a fasting stomach. Glycemia increased slightly or did not change in persons of the first group and decreased or did not change in the persons of the second and third groups. It is not possible to know whether the changes of glycemia following the administration of bile derivatives are due to an action of the latter on the liver or on the pancreas.

Anterolateral Thoracoplasty by Mondaldi's Technique in Pulmonary Tuberculosis. F. Buonomo La Rosa—p. 544

Vomiting in Children. C. De Ritis—p. 549

Posterior Tuberculous Sacral Para-Arthritis.—Taddei calls tuberculous sacral para-arthritis the disease reported in the French literature with the name of partial or atypical forms of sacro-iliac tuberculous arthritis. The condition is neither an atypical nor an incomplete form of sacro-iliac arthritis, but a localization of tuberculosis at the epiphysis near the symphysis of the sacro-iliac joint. Both arthritis and para-arthritis of the sacro-iliac joint originate in the primary parasympathetic tuberculosis, but their clinical picture and evolution are different. In arthritis the joint is involved and there is no abscess formation. In para-arthritis the joint is spared in the process and an abscess is formed. Tuberculous sacral para-arthritis develops in two periods, one of intense pain of the type of rheumatic sciatica, which does not improve by rest of the patient, and one of amelioration of the pain and formation of a parasympathetic abscess. There is only one internal painful spot above the fistula which persists all through the disease. Of most diagnostic value, however, is the presence of rigidity of the vertebral lumbar segment to flexion but not to extension of the column. Rigidity of the vertebral segment is characteristic of tuberculous sacral para-arthritis and is of value in the differential diagnosis with Pott's disease, tuberculous sacro-iliac arthritis and other vertebral and sacro-iliac pathologic conditions in which it does not exist. The treatment of tuberculous sacral para-arthritis depends on the evolution, either anterior or posterior, of the abscess. In some cases the abscess develops anteriorly and opens spontaneously in the pelvis or the internal organs. In these cases the common treatment of tuberculous abscess gives satisfactory results. In other cases the abscess develops posteriorly into the gluteal insertions, through which it spontaneously opens to the exterior, leaving a fistula. Para-arthritis of posterior development is grave. The treatment is surgical and consists in removal of the cutaneous ulcer, the wall, the abscess and the fistulous tract and in scraping or typical resection of the tuberculous focus of the bone. A case of posterior development is reported in a patient, aged 19, suffering from pulmonary and lymph node tuberculosis.

Magnesium Sulfate by Vein for Asthma.—Rosello and Pla state that the intravenous injection of a 10 per cent solution of magnesium sulfate, in doses of from 10 to 20 cc. each, produced an intense and immediate sedative effect in an asthmatic patient during a crisis which had failed to respond to epinephrine, ephedrine, solanaceous drugs, atropine and morphine. The action of magnesium sulfate, however, is transient and the injections have to be repeated in order to maintain the antispasmodic effect until the crisis disappears. The injections should be given slowly. The authors have not exceeded a 10 per cent solution. It is possible to inject calcium chloride immediately after the magnesium sulfate if an intense reaction develops. Magnesium sulfate because of its antispasmodic properties, gives satisfactory results in cases of cortical or reflex hyperexcitability of the central nervous system (eclampsia, tetanus, chorea, strychnine poisoning and certain sequelae of parkinsonism). Magnesium thiosulfate gives satisfactory results in certain conditions of shock (including asthma) and in other paroxysmal conditions. The authors cannot state as yet whether

magnesium sulfate, besides being an antispasmodic, may have regulating properties of the equilibrium of the humors, the blood plasma and other factors that may take a part in producing the crisis of asthma, a question that they promise to clarify in the near future by animal experiments

Reciprocal Influence of Blood Bilirubin and Blood Urobilin Eliminated Through Bile M Royer and A Speroni — p 89

Syphilis by Contagion in Girl Aged 5 Case A Aurelio Fernández and L Iapalucci — p 91

Pseudobulbar Syndrome R Soto Romay — p 100

Spinal Anesthesia in Labor R L Gaviohi — p 119

Bilirubin and Urobilin—Royer and Speroni studied the reciprocal influence of blood bilirubin and blood urobilin when the elimination of the pigments through the bile was induced by the intravenous injection of either pigment. The influence was evaluated by the changes of the bilirubin-urobilin ratio in the canalicular bile, obtained by duodenal sounding in three cholecystomized persons. Following the intravenous injection of bilirubin, the bilirubin secretion increases in the bile. The urobilin secretion slightly increases, but the curves of both secretions are independent. The bilirubin-urobilin ratio shows great variations in a few minutes. Following the intravenous injection of urobilin in doses of 2 mg of urobilin for 5 Kg of body weight, the bilirubin secretion in the bile increases five times as much as it was before the injection while the urobilin secretion increases thirty two or forty-eight times as much. The bilirubin-urobilin ratio greatly decreases. The authors say that, although there is a reciprocal influence between blood bilirubin and urobilin in their elimination through the bile, the bilirubin-urobilin ratio varies in the same person and under the same conditions, according to the amount of either pigment in the blood.

Intra-Uterine Function of Fetal Lung and Liver—Szendi searched in human and rabbit embryos for the organs that influence the intra-uterine carbohydrate metabolism. He investigated the glycogen content of the organs of spontaneously and artificially aborted fetuses. He found that the lungs and the liver develop into glycogen organs. The glycogen content increases and decreases independently of the growth or weight of these organs, but a certain regularity is perceptible which is connected with the anatomic structure. This and the considerable accumulation of carbohydrates indicate that these organs with their great masses of glycogen take part in the regulation of the carbohydrate metabolism of the fetus. Lungs and liver act alternately on the fetal carbohydrate metabolism, for first it is done by the lungs (in human embryos between the second or third and the sixth or seventh months and in rabbits between the eighteenth and twenty-fifth days). During this time, the liver is active in the formation of blood. After that, however the liver gradually assumes a greater importance in the carbohydrate metabolism, for during this time lungs and liver are being prepared for their extra-uterine functions. The author concludes that, during the intra-uterine period the lung is not merely a developing organ, as was believed formerly, but takes part in the carbohydrate metabolism that is, it has a function which differs from its extra-uterine activity. He found also that heart and muscles have comparatively large quantities of glycogen and believes that the glycogen in the muscles is probably a secondary carbohydrate reserve. He

observed that, on the whole, the fetal organs contain more glycogen than do the organs during postnatal life and he assumes that they probably require it for their development, for the intensive increase in cells and for other functions as yet unknown.

Metabolically Active Substances from Ovarian Follicle—Anselmino and Hoffmann demonstrate that purified extracts from ovaries and from follicular juice which are free from corpus luteum hormone, produce in the animal experiment a number of characteristic metabolic effects. For instance, they observed after the administration of active extracts an increase in the basal metabolism, a heightening of the blood calcium level, an increased formation of ketone bodies in the blood and an intensified insulin blood sugar action. In contradistinction to this, the crystalline alpha follicle hormone, which is obtained from pregnancy urine and the dihydro-follicle hormone proved entirely inactive just as the extracts prepared in the same manner from liver and spleen are without metabolic action. From these observations the authors conclude that the estrogenic hormone, which is extracted from the urine and assayed according to the Allen Doisy test is not identical with the metabolically active components of the ovarian follicles. The extracts investigated by the authors exert their action (as regards basal metabolism and calcium content of the blood) by a stimulation of the secretory glands, for they are inactive after removal of the thyroid and the parathyroids. The exact action mechanism, however, is not understood as yet. After calling attention to the isomeres or related substances of the estrogenic hormone, which have been prepared by chemists from pregnancy urine, the authors state that they tested the metabolic action of two such substances and found that they lacked a metabolic action. They reach the conclusion that it is no longer permissible to regard the alpha follicle hormone and the dihydrofollicle hormone as the only active substances of the follicle. They point out that certain clinical observations, such as the unsatisfactory results obtained in menopausal disorders with the estrogenic substance extracted from the urine, corroborate their opinion. They advise that in the future more attention be given to the metabolically active substances of the ovary.

*Icterus Gravis with Eclampsia in Child During First Year of Life E Lohse — p 40

Icterus Gravis with Eclampsia in Child—Lohse reports the history of a boy, aged 11 months, the fifth child of apparently healthy parents. However, two of the other four children had died one at the age of 4½ months, as the result of intestinal catarrh, and one after three days with cerebral symptoms. The child under consideration had been subject to attacks of twitching and rigidity but allegedly had never had nutritional disturbances. The child had once been treated for catarrhal conjunctivitis and once for a mild bronchitis. The Wassermann reaction was negative twice. The present disorder began with fever three days before hospitalization and terminated fatally on the sixth day after admittance. The author gives a detailed description of the clinical and histologic aspects. In discussing the case he says that two processes apparently developed in the liver: a chronic disorder, namely, a diffuse proliferation of the connective tissue and of the bile ducts, and an acute process in the form of a fatty degeneration of the liver cells focal hemorrhages and necroses, and increase in cells without signs of organization. Since syphilis can be excluded, it must be assumed that the child had been subject to repeated intoxications probably of an alimentary nature. Their cumulative action produced chronic changes similar to those appearing in syphilis, but at first they did not result in insufficiency of the organ. A last acute intoxication led to complete failure of the hepatic function. This together with an acute disorder of the kidney was followed by the fatal outcome with severe cere-

bral symptoms. To be sure, it is surprising that the anamnesis does not indicate such disorders. The author suggests that mild toxic impairment may perhaps have been overlooked. With regard to the eclamptic symptoms, which developed on the last day, he says that cerebral symptoms are not unusual in the course of icterus gravis, in that they are a manifestation of a hepatic auto-intoxication. The character of the disorders (alimentary intoxication and eclampsia) in the two other children, who had died, suggests a predisposition in the children of this family.

Psychic Factors in Pulmonary Tuberculosis—Bargłowski maintains that a detailed psychic anamnesis of patients with pulmonary tuberculosis reveals frequently that the outbreak of the disease was preceded by psychic conflicts. He reports the psychic anamneses of five patients which indicate that psychic conflicts and traumas are at least contributing factors in that they reduce the resistance of the organism and thus prepare a favorable field for the action of the tubercle bacilli. Since the psychic conflicts persist frequently after the outbreak of the disease and are likely to exert an unfavorable effect on the curative process, psychotherapy is advisable for such patients.

Serodiagnosis of Tuberculosis—Zeyland and Piasecka-Zeyland made 763 flocculation tests according to Meimcke's vault or curvature method. However they limit their discussion to the 479 cases in which the existence of tuberculosis was definitely established. In 148 cases they compared the results with those of the complement fixation test according to Calmette-Massol with the methyl antigen of Nègre and Boquet. The authors reach the conclusion that although its technique is simple, the Meimcke reaction is as reliable as the best complement fixation tests, and it is even superior to the complement fixation test made with the methyl antigen. However, its value for the diagnosis of tuberculosis is nevertheless slight, for it gave positive results in 80 per cent of the adults with tuberculosis, in 20 per cent of the control cases (nontuberculous serums) and in only 50 per cent of the children with active tuberculosis.

"Tumor Colli" as Symptom of Malignant Tumors in Throat.—Kreyberg says that a tumor in the neck is often the first symptom in this group of tumors, which presents three main types: transitional cell carcinomas, lympho-epitheliomas and reticulosarcomas. In a number of cases histologic differential diagnosis between these types is simple; in other cases differential diagnosis is impossible with the present technique. The reticulosarcomas are tentatively divided into three subgroups: (1) those with alveolar growth; (2) those with diffuse syncytial growth by rather uniform cells; and (3) those with diffuse growth by individual, more polymorphous cells. Except when the primary tumor is in the lymph nodes of the neck, it is usually in the nasopharynx or tonsils. Every case of a lump in the neck in an adult calls for examination of the throat by a competent rhinologist if the cause of the tumor is not evident. An amateur in rhinoscopy may easily miss a primary silent tumor in this region as it appears only as a small flat

infiltration of the nasopharyngeal wall. All these tumors are to be regarded as roentgen sensitive, some to a marked degree, and treatment is mainly roentgenologic. Prognosis is as a rule grave, because of metastasis formation. Improvement in the results depends chiefly on earlier diagnosis. Nineteen certain and two doubtful cases are reported.

Xanthomatosis and Sudden Death—Harbitz describes a case of sudden death in a man, aged 46. There were hard nodular, yellow deposits 3 or 4 cm long on the backs of his hands and coherent with the tendon sheaths. Microscopic examination showed typical xanthomas. The heart was hypertrophic, somewhat infiltrated with fat, and in the right and especially in the left coronary artery were considerable deposits of yellow-white masses, which had caused strictures in various places. Similar deposits, intensely yellow, were also present in the aorta opposite the valves and to a greater extent in the abdominal aorta. The cholesterol content of the blood plasma was normal 171 mg per hundred cubic centimeters. The author states that two patients with a history of multiple xanthomas beneath the skin in childhood, described by him in 1925, died suddenly, both at the age of 22. Necropsy performed in one case revealed large xanthomatous deposits in the aortic valves and in the aorta, with stenosis and hypertrophy of the heart. At 18 this patient's blood plasma had contained from 470 to 547 mg of cholesterol esters per hundred cubic centimeters. The father of the other patient, five paternal uncles, an aunt and an uncle on the maternal side had xanthomatosis, although in far less marked form, two brothers and a sister were well.

Acquired Tertiary Pulmonary Syphilis—Strandgaard reports one certain and three probable cases of this disorder, all seen within a year, which he says, shows that the disorder, though rare, is a possibility to be considered in the diagnosis of chronic pulmonary disturbances. In the first patient a woman, aged 43 without known preceding syphilitic infection, a chronic progressive pulmonary ailment marked by pronounced dyspnea and cyanosis set in at the age of 38. The Wassermann reaction was positive, no tubercle bacilli were found. Necropsy revealed an extensive fibrous shrinking pulmonary process. Histologically there was marked fibrosis without signs of specifically tuberculous tissue. The macroscopic and microscopic diagnosis was chronic fibrous syphilitic pneumonia. The other patients were men. In one without known syphilitic infection, signs of tabes dorsalis developed at the age of 38, with simultaneous cough and expectoration subordinate to the tabetic symptoms but continuing unchanged for about twenty years. There were stethoscopic signs of a chronic process basally in the lung, and roentgen examination showed clarifications surrounded by fibrous parts. The Wassermann reaction was negative. The next patient infected with syphilis at the age of 18 had apparently been well until 50, when coughing with expectoration began and continued for about ten years. Fibrous processes were seen in the lower part of both lungs. The Mantoux reaction was negative, tubercle bacilli were not found and the Wassermann reaction was positive. Treatment with arsphenamine and potassium iodide produced no decisive changes in the picture. The last patient, at the age of 44 had a recent syphilitic infection which was treated energetically. It was shortly followed by continuing cough and expectoration. Nine years later there were signs of chronic pulmonary disturbance at the base of both lungs. The Wassermann reaction was not negative; there were no tubercle bacilli in the sputum. Long continued treatment partly antisyphilitic partly with short wave diathermy partly with roentgen rays brought no decided improvement.

PHYSIOLOGIC EFFECTS OF THE CORRECTION OF FAULTY POSTURE

LOUIS B LAPLACE, MD
AND
JESSE T NICHOLSON, MD
PHILADELPHIA

Postural defects of the kypholordotic type are often productive of painful manifestations that are easily relieved by proper corrective exercises. In addition, however, postural defects are also generally believed to be a handicap to various physiologic functions of the body.¹ The following observations, which are supplementary to those reported in a previous paper,² have been made in an effort to determine to what extent this belief is justified by clinical and experimental evidence, also to evaluate what benefit, other than relief of pain, may be anticipated from the orthopedic correction of faulty posture.

METHODS

Observations were made on a series of twenty-six healthy adults of both sexes having disorders of the back attributable to postural strain. All subjects had received instructions in the correction of their postural defects. Twenty-three subjects were studied with respect to the immediate physiologic effects of changing from a faulty posture to a corrected posture, eight of these were further studied with respect to the degree of permanence of these effects following a year of routine corrective exercises. The following studies were carried out in both correct and faulty postures on the same day and (in eight subjects) after an interval of one year.

1 Orthodiagrams, with special reference to the thoracic and cardiac measurements and the maximum diaphragmatic excursions (Diaphragmatic measurements were made from the highest point of the dome)

2 Estimations of vital capacity

3 Electrocardiograms

4 Estimations of oxygen consumption, respiratory rate tidal air and respiratory minute volume (obtained by means of a standard oxygen filled spirometer for metabolism determination)

5 Repeated estimations of blood pressure and pulse rate over ten minute periods with preceding and intervening ten minute periods during which the subject

was recumbent. A rating for circulatory efficiency was thus obtained by subjecting these values to the criteria of Turner.³

RESULTS

Immediate Effects—The immediate effects of correcting faulty posture are outlined in table 1. From these results it is apparent that there is surprisingly little uniformity in the effects of postural correction between different individuals. These individual variations could not be correlated with the extent of the postural defect nor could the reaction of any particular subject be predicted in any way. It may be reasonably concluded from this that the correction of faulty posture must afford a variable degree of benefit to different individuals and that its effect is generally unrelated to the grade of the postural error. This conclusion is borne out by the following detailed consideration of the influence of posture on the circulatory and respiratory function of the body.

Transverse Diameter of the Chest—On assuming a corrected posture, the transverse diameter of the chest (made in the position of normal expiration) was increased in eight subjects, unchanged in eleven and decreased in four. The inconstancy of this change is attributed to the fact that the increase in the transverse diameter in the good posture may be slight or nil compared to the increase in the anteroposterior diameter, furthermore, it was observed that in the faulty posture the lower part of the chest, in the presence of marked kyphosis with little increase in lumbar lordosis, may be expanded as the result of upward compression of the abdominal viscera.

Position of the Diaphragm—It has been stated that the diaphragm is characteristically elevated in the corrected posture.¹ In the present study this did not always appear to be the case for the correction of posture was associated with an elevation of the diaphragm in only ten subjects whereas the height of the diaphragm was unchanged in four subjects and was decreased in nine. It seems quite evident why the diaphragm is not necessarily higher in the corrected posture (figs 1 and 2). When the thoracic spine is straightened the chest is elongated and the diaphragm although higher with respect to the sacrum, may actually be lower with respect to the first ribs (from which the accompanying measurements were made). Moreover, in cases presenting increased kyphosis, the slumped posture may cause the higher elevation of the diaphragm by upward compression of the abdominal viscera. It is probably for the latter reason that in at least eight instances the normal excursions of the diaphragm were greater in the position in which the diaphragm was low rather than high.

Laplace L B and Nicholson J T. Observations on Some of the Physiologic Effects of the Correction of Faulty Posture. *Am J M Sc* to be published.

Position of the Heart—It has also been stated that the heart is characteristically more transverse in the corrected posture, owing to the higher position of the diaphragm.¹ In the present study, however, the heart became more transverse in the corrected posture in only six instances, in seven there was no significant

change, while in ten the transverse diameter of the heart was decreased. The change in position of the heart was confirmed by a corresponding axis deviation of the electrocardiogram in all but two cases. (These two discrepancies are probably attributable to the fact that the electrical axis of the heart may be shifted in the opposite direc-

Fig 1—Orthodiagram showing higher diaphragm and more transverse heart associated with the corrected posture. The solid line indicates the corrected posture, the broken line the faulty posture.

tion by rotation and lateral displacement of the heart. Rotation and lateral displacement of the heart were often observed under the fluoroscope.) The ten instances in which the heart did not become more transverse on elevation of the diaphragm may be explained by the fact that, first, when the thoracic spine is straightened the heart is elevated by its attachments to the cervical fascia and tends to become more dependent, and, second, when the heart is pushed upward by the diaphragm it sometimes rotates around its vertical axis so that its anteroposterior silhouette may appear less wide. No obvious relationship was noted between the position of the heart and the circulatory efficiency, although such a relationship undoubtedly exists in extreme cases and probably also in certain cases of organic heart disease.

Diaphragmatic Excursions—In the corrected posture the extent of the diaphragmatic excursions between

therefore, manifestly tends to increase the vital capacity, and since this function is closely correlated with cardiovascular efficiency it is reasonable to conclude on this basis that a correct posture is a substantial benefit to the circulation. On the other hand, it should be pointed out that, when erect many subjects stooped somewhat to complete expiration and when slumped, became momentarily more erect during the preliminary inspiration. In fact it was quite evident that the vital capacity is really diminished by extreme correction of posture as well as by a marked slump and that a certain degree of flexibility is requisite for optimum results.

Electrocardiogram—Change of posture produced no significant alteration of the electrocardiogram other than deviation of the electrical axis, as previously noted. Occasionally the amplitude of the T waves in lead 3 was correspondingly modified.

Oxygen Consumption—In the corrected posture the oxygen consumption was increased in seven subjects, unchanged in eight and decreased in six. (The limit of experimental error was arbitrarily set at 25 cc.) Although these figures are inconclusive, the impression was gained that the corrected posture tends to be associated with a relatively lower oxygen consumption, but higher values are obtained in those instances in which the subject exerts unusual physical effort in maintaining his correction.

Respiration—In the corrected posture the depth of respiration (tidal air) was increased in fifteen subjects, unchanged in three and decreased in five. Increase in

Fig 2—Orthodiagram showing lower diaphragm and more dependent heart associated with the corrected posture. The solid line indicates the corrected posture, the broken line the faulty posture.

In these tables 0 indicates no change on shifting from a faulty to a correct posture + increase - decrease

maximum inspiration and expiration was increased in nine subjects, unchanged in four and decreased in nine. The extent of the diaphragmatic excursions appeared to be unrelated either to the type of posture assumed or to any of the recorded effects that might be attributed to posture. It has no obvious correlation with the vital capacity or with the average depth of respiration.

Vital Capacity—In the corrected posture the vital capacity was increased in fourteen subjects, unchanged in five and decreased in three. A correct posture

the depth of respiration was characteristically accompanied by a slowing of the respiratory rate and an increase in respiratory minute volume (fig 3) which occurred in ten subjects, and the reverse of which did not occur in any. The explanation probably depends on the facilitation of thoracic excursion by the corrected posture with resultant deeper and therefore slower respirations. It is noteworthy, however, that in at least six subjects pulmonary ventilation was unchanged or diminished.

Circulatory Efficiency—The criterion for the estimation of circulatory efficiency, according to Turner,³ is the degree to which the pulse rate, blood pressure and pulse pressure are maintained within normal physiologic limits on prolonged standing. Applied in the present study, this test indicated that in the cor-

| | Good posture | Poor posture |
|---------------------------|--------------|--------------|

| Respiratory minute volume | 12 850 | 9 820 |
| Oxygen consumption | 263 cc. | 246 cc. |

rected posture circulatory efficiency was increased in fourteen subjects, unchanged in seven and decreased in two. Of those subjects who showed an increase, the difference between the two postures was not very great except in a few cases, two of which were really striking. In these the circulation was entirely normal in the corrected posture, but when a slump was assumed the pulse rate increased and the blood pres-

sure fell until signs of actual syncope appeared (fig. 4). From these results, a corrected posture may be considered to be an appreciable advantage to the circulation in approximately 50 per cent of normal individuals, in about 15 per cent this advantage is very great, while in the same number the circulatory efficiency is definitely improved by a certain degree of postural slump.

Results After One Year—It is of interest to note that, of fifty subjects who had been advised to continue their routine postural exercises, only eight could be found who, free from symptoms after one year, had improved their posture sufficiently to warrant inclusion in this study (table 2). Of these eight, six showed some increase in circulatory efficiency, four showed an increase in vital capacity, two showed

increase in height of diaphragm, and four showed the characteristic slowing of the respiratory rate with increased tidal air and minute volume. Thus, there is some evidence of improved posture and its effects in the majority of cases, but the results are not remarkable. Nor can it be said that such further training as these subjects have obtained has made them any more efficient physiologically than on their first examination for this study (table 3). Comparison of the immediate effects of postural correction with the results obtained in the group of subjects who have had prolonged training, therefore, indicates that the two may be considered to be entirely comparable.

COMMENT

Considering the results of this study in general, the outstanding conclusion to be drawn is the fact that straightening of the spine does not produce the same anatomic and functional changes in all subjects. It is also evident that, although a correct posture is of some advantage to the majority of subjects, it is not so to all. Judged by the evidence of the present work, there are many persons whose optimum physiologic function is attained in a posture which is not entirely correct by orthopedic standards. Perhaps in such persons the greater spinal curve represents a compensatory mecha-

Fig. 4—Successive blood pressure and pulse rate estimations showing the comparative effects of corrected and faulty posture.

nism determined by individual differences of body structure and physical activity. In cases of emphysema, for example, if the corrected posture should produce a lower rather than a higher diaphragm (as often occurred in the present study), a postural slump would certainly act in a compensatory capacity. On the other hand at least two subjects were found in this

series whose circulatory efficiency depended very largely on the maintenance of a correct posture. To the authors it has therefore been forcefully demonstrated that the orthopedic correction of faulty posture may produce valuable therapeutic results in many cases, that in other cases a rigid correction of posture may prove a physiologic handicap and, finally, that every person has a certain posture, determined by his particular build and function, which is best suited to him. It is only by study of the individual patient and the correct appraisal of his optimum posture that the best therapeutic results can be obtained.

SUMMARY AND CONCLUSIONS

1 Twenty-six subjects having postural defects of the kypholordotic type were studied with respect to the physiologic changes produced by the correction of their faulty posture. The immediate effects were in general entirely comparable to those observed after one year of corrective exercises.

2 In the corrected posture the diaphragm was not always relatively elevated as is generally believed, nor was the heart always more transversely placed. The diaphragmatic excursions were either increased or decreased, for reasons that are discussed. The vital capacity was generally increased, although flexibility of posture was requisite for optimum results. Oxygen consumption was variable. Pulmonary ventilation was generally increased. Circulatory efficiency, as judged by constancy of blood pressure and pulse rate, was generally improved, in two cases the correction of posture was able to prevent hypostatic congestion and syncope.

3 It was concluded that the results of correcting faulty posture differ widely between individuals, irrespective of the grade of the defect. A correct posture appears to be an appreciable advantage to circulatory and respiratory function in the majority of persons, but in some a postural defect may be a compensatory mechanism which it is inadvisable to disturb. The therapeutic application of postural correction should be made according to the requirements of the individual case and only after an attempt to determine in what posture the individual is functionally most efficient.

1900 Rittenhouse Square—1726 Spruce Street

ABSTRACT OF DISCUSSION

DR. JOHN G. KUHN, Boston. The tests employed by Drs. Laplace and Nicholson are probably as accurate as any of the simpler ones. It is unfortunate that a larger number of individuals were not available. The changes observed would probably have been changed little, but greater reliance could have been placed on the data from such careful experiments. It is customary to measure good posture by decrease in the anteroposterior spinal curves. But with the marked individual variations in body build, no one standard can be set up that will define the mechanically best for each individual. This wide variation must be realized when one judges patients by present imperfect standards. When the patient has constant good posture one expects to find, in addition to the decrease in the spinal curves, an elevation of the chest, so that it is used habitually in the position of almost full inspiration and a rounding and firmness of the upper portion of the abdomen anteriorly. Then, too, there are no accurate measurements of health or well being, and tests of the efficiency of various bodily functions must be interpreted freely since there are wide normal variations. The immediate effects of correcting faulty posture should differ particularly in relation to the effort that is expended in maintaining the correction. The length of time that the correction is maintained should also produce changes in the effects observed. The transverse diameter of the chest

while susceptible of some immediate change with elevation of the ribs, has been found to increase steadily over a period of several years with postural exercises. Upward compression of the abdominal viscera in marked kyphosis may well increase the expansion of the lower ribs. The elevation of the diaphragm is not a constant finding in early attempts at correction of posture, but it has been observed in all cases except when adhesions or some mechanical obstruction were present, after good posture had become habitual. Habitual maintenance of good posture may require months or years, since it is a development of conditioned reflexes, which are acquired slowly. The position of the heart has been looked on to be a characteristic as Stoll has observed, of the type of body, whether slender or stocky. Often a more transverse position is not assumed, but a higher position is seen in the thoracic cavity. This can be measured by the rib spaces, either the cardiac apex or the aortic arch being taken in successive roentgenograms. The diaphragmatic excursions vary widely. Increase in the normal excursions is usually observed with long continued correction. I have rarely seen it as an immediate effect. Increase in vital capacity, with correction of faulty posture, has been a constant finding by most students of this problem. Immediate or extreme attempts at correction of posture will frequently put so great a task on the musculature of the thorax and abdomen that vital capacity will be diminished. In a few experiments that I have carried out, no appreciable difference was seen in the electrocardiogram with corrected posture. Knopf has arrived at figures similar to those obtained by Drs. Laplace and Nicholson with regard to oxygen consumption and respiratory rate following postural correction, and my observations are entirely in accord with them. In the circulatory efficiency tests of Dr. Turner there are a great many factors that are beyond the control of the examiner. It is unfortunate that more rigid ones are not available. As the authors have found, the immediate effects of postural correction are very variable, but they suggest that persistent attempts at correction are frequently of therapeutic value.

A CONSERVATIVE TREATMENT FOR HABITUAL DISLOCATIONS OF THE SHOULDER

ARTHUR G. DAVIS, M.D.
ERIE, PA.

It appears highly desirable to have some conservative method as an alternative to the surgical approach for recurrent dislocations of the shoulder. Search for a plan of conservative treatment failed to reveal anything by way of a definitely formulated technic. Bennett, Codman, Key and Conwell suggest the advisability of general shoulder development and Codman describes a method of training the patient to guard against future dislocations. Before and contemporary with the era of the Clairemont operation there were various suggestions of splints to limit abduction. This article purports to outline a conservative plan and analyze the results of cases treated by this method.

It is generally conceded that the shoulder joint is the most unstable of the entire anatomy. It is also admitted that the actual mechanics and kinetics are still only partly understood. Considerable divergence of opinion as regards etiology and operative attack is exhibited by both author and operator.

It would seem necessary, therefore, to preface a description of any method aimed at the permanent cure of recurrent dislocations with an interpretation of the generalities involved. Codman's work has shown in detail the wide departure of the human shoulder from that of the quadruped. Its high degree of specializa-

Read before the Section on Orthopedic Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

tion in function has been pointed out by many. The evolutionary process has robbed the shoulder of its anterior muscle guard. That muscle integrity is fundamental to the integrity of the joint is a matter of daily observation. Nevertheless, muscle integrity alone is not sufficient to insure mechanical security, as evidenced by the repeated dislocation of heavily muscled shoulders. The anterior inferior section of the capsule is known to be the weakest portion. It is generally appre-

encouraged to use the arm as well as he can within the limits of the adhesive splintage. He is then instructed in a definite technic of muscle development. He is equipped with apparatus for home use to develop increasing resistive exercise. For two or three weeks his exercises are closely supervised to inculcate correct technic. With a band around the arm just above the elbow he pulls a weight horizontally across the frontal plane to strengthen the adductors. Simultaneously, he

ciated that a first dislocation should be considered a major injury and given proper convalescent care, with the anterior capsule especially in mind.

METHOD

The patient is strapped with ordinary adhesive tape in the following manner (figs 1 and 2). Strap 1 starts in the posterior deltoid region at the level of the surgical neck and proceeds around, forward and then across the patient to be affixed to the sternal region. Strap 2 starts at the postero-internal aspect of the arm just above the elbow, spirals outward upward and then forward, crossing the front of the mid upper arm, and attaches to the sternal region. The arm is thus not allowed to move backward to the coronal plane. The elbow not only is not allowed to abduct but is held adducted inside the lateral sagittal plane. The patient has not lost use of his arm during treatment but is

instructed to pronate his hand and rotate the entire arm internally to overdevelop the internal rotators. The resultant of these three components of movement is a spiral thrust across the abdomen and toward the opposite thigh. The ability of patients to increase the poundage of pull is surprising. The pectoralis major and anterior deltoid develop increased power quickly. By inference it is obvious that the subscapularis, teres minor and latissimus dorsi must also hypertrophy.

At two weeks the adhesive tape is removed and one finds that the patient has acquired the habit of getting along without abduction and without his hip pocket. He is then instructed to continue with his home apparatus for another month after which he is usually somewhat arbitrarily turned loose and instructed to engage unrestrictedly in his occupation, whatever it is.

In the accompanying table are listed the cases which form a consecutive series in private practice.

COMMENT

Case Citations—Roentgenography exhibited no evidence in any case of congenital anomaly or other pathologic condition of the bone. All eight cases were considered from both the operative and the conservative approach when first seen. All were considered eligible for the Henderson or some equivalent operative approach, such as the more recent DiNicola procedure

Fig. 1—Attitude at beginning of internal rotation thrust

The failure in the case of W. P. was not known until a few months ago. This patient will be operated on in the near future. The other failure (A. P.) is the most unstable of the group. In this patient it is possible to dislocate the head passively with even gentle pressure. At the time of her first appearance, failure by the conservative method was predicted, because of the very unusual laxity combined with an extremely weak deltoid. In answer to a recent questionnaire this patient states that she is comfortably at work and has no painful disability but that her shoulder "pops out" on the average of once a day. So far no cases of epileptic dislocation have occurred in this series, therefore I know nothing of the effect of this treatment in epileptic patients.

As stated before, the cases cited are a consecutive series in private practice. Ward and clinic cases, of which there have been six or eight, have been done by the Henderson suspension method, with the excep-

Fig. 2—Attitude at end of internal rotation thrust

tion of two, which were done by the DiNicola biceps transposition. An orderly sequence of follow up has been impossible in the surgical cases. So far as I know all of these cases have been successful.

Method—In formulating the technic the following factors are interpreted as having a direct bearing either as fortifying or as compensatory mechanisms. The temporary overdevelopment of internal rotators and adductors tends to shorten the anterior capsule and

restore the correct axial alignment of the head of the humerus with the glenoid. If the balance of power is in favor of the external rotators, the bicipital groove robs the anterior capsule of an important check strap, the long head of the biceps. The bicipital groove is capable, as is the entire humerus, of 90 degrees of rotation (fig. 3). When the balance of power is returned to the adductor and internal rotator groups, the biceps check strap, it is thought, exerts pressure backward and medially on the head. When the arm is habitually carried with more than the average degree of external rotation, sudden efforts involving abduction find both the long head of the biceps and the external rotators exerting pressure forward against the notoriously weak anterior capsule. Figure 3 shows clearly the change in position from anterolateral to posterolateral of the biceps and bicipital groove. If the transpositioning of the biceps as shown by Dr. DiNicola is sufficient per se to hold the head, then the biceps in its normal anterior position is also important. When the humerus is in wide external rotation, the greatest diameter of the head is brought against

Fig. 3—Arc of rotation in the cadaver (reproduced by courtesy of E. A. Codman)

the anterior capsule. If the shoulder has been once dislocated and the capsule is not allowed to shorten, the head finds less resistance in this position. The head then exerts expansive pressure against the anterior capsule, which fact explains the usual sequence of the increased frequency of dislocations that are usually experienced.

Additional evidence of the role of the tendon of the long head of the biceps is suggested by the lateral displacement that has taken place in the transition from the quadrupedal attitude of internal rotation and pronation to the erect biped position of increasing supination and external rotation. If one simply puts one's hands on the floor (assumes the position of a quadruped) and then arises to the standing position, the humerus externally rotates approximately 45 degrees.

The aim of the conservative approach is directed at fortifying the anterior aspect of the joint, just as the numerous operative methods focus attention at this point. The strapping and exercises are also used as a convalescent treatment for ordinary traumatic dislocations.

IMPRESSIONS

- 1 The treatment outlined has eliminated the necessity of operative measures in 75 per cent of a consecutive series of typical recurrent dislocations.
- 2 The patient is only somewhat disabled during a short period of treatment.

3 The evidence submitted suggests that this short period of treatment yields results of a permanent kind and therefore offers an alternative to operative approach

ABSTRACT OF DISCUSSION

DR. ENOS B. FOWLER, EVANSTON, ILL. Dr. Davis's conservative treatment of habitual dislocation of the shoulder consists of an attempt to strengthen by exercise, with restricted motions, structures about the shoulder joint, of which the muscles and their tendons play a major role, while the capsule plays a minor part in the prevention of dislocations. The report of eight cases with 75 per cent of cures at the end of two years is encouraging and compares favorably with operative results. Dr. Davis feels that the anterior weaker portion of the capsule is subject to rupture, tearing or injury and therefore he is careful to put the arm so as to facilitate repair and contraction of the supposed injured dilapidated anterior capsule. He also feels that the tendon of the long head of the biceps is placed in the best position to assist in preventing dislocation if the humerus is well rotated internally. I believe that the anterior capsule, though relatively weak, is practically never torn, ruptured or appreciably stretched. This conviction is based on a study of 621 shoulders in the past five years, in which no traces of scars, rents or stretching could be found on either the anterior or the inferior portion of the capsule. On the other hand, in the upper portion of the capsule with its associated tendons, there were found thirty-four complete and 101 incomplete ruptures of the capsule and tendon or tendons along with twelve complete ruptures of the long biceps tendon. These lesions increased the extent of the capsule space with a resulting unstable shoulder joint because of relaxed, lengthened tendons and capsule on the upper quadrant of the capsule. I believe that such traumatized shoulders are rarely, if ever, cured by conservative treatment, unless proper treatment is instituted at the time of the rupture. This conservative treatment consists in placing the arm in a nearly vertical position with the forearm flexed and held from six to eight weeks until the torn parts have firmly united, thus there is no relaxation of the tendons or capsule, accordingly there is no predisposition to redislocate.

DR. ARTHUR G. DAVIS, ERIC, PA. With the present status of disagreement even among contributors such as Codman, Steindler and Fowler, who have made a special study of the anatomy and kinetics of the shoulder joint, one is permitted considerable leeway for interpretation as to what constitutes normal muscle action. Gray studiously avoids many of these unsettled intricacies. One of the points of almost unanimous agreement among contributors to shoulder joint surgery is the anterior, inferior weakness of the capsule. As already mentioned in the text, my interpretation leads me to explain the successful results through the fact that, when the anterior muscle guard is off, in other words when principally the subscapularis and anterior deltoid are stretched, the balance is in favor of the external rotators, the long head of the biceps loses its check strap effect through lateral rotatory displacement, all of which favors anterior dislocation. Regarding type, no conclusions can be drawn. The heavily muscled and atonic, posturally good and posturally weak all appear in this series. In the two failures, I hope, the patients will both submit to operative procedures. I have recommended a Henderson suspension for one. I feel no hesitancy about doing a Henderson tenosuspension or a Di Nicola biceps transpositioning when conservative treatment fails. Obviously, from the evidence submitted some cases will require operative intervention. Percentage data are significant proportionately to the total number involved. What a series of 100 cases would yield by conservative method is problematic. I do know that the necessity of operation has been eliminated in six out of a consecutive series of eight cases of typical habitual dislocations, mostly in young persons.

Eating When Exhausted—When it is necessary to eat while emotionally upset or physically exhausted, it is advisable to rely upon dilute, easily digested foods.—Sherman, H. C. Food and Health, New York. Macmillan Company, 1934

GLOSSOPHARYNGEAL NEURALGIA

W. B. HOOVER, M.D.

AND

J. L. POPPEN, M.D.

BOSTON

Tic douloureux involving the glossopharyngeal nerve became a well established clinical entity between the years 1920 and 1927. Since its recognition has been quite recent and because it has been frequently unrecognized, we believe that the following report of two cases with a brief review of the literature is worth while.

REPORT OF CASES

CASE 1—J. L. C., a man, aged 59, an American of Irish extraction who had worked as a gardener was referred to the clinic because of severe pains in the left side of the throat and ear. His present illness began suddenly fourteen months previous to admission. At that time while quietly working in the garden, he was seized with a sudden sharp paroxysm of pain in the left side of the throat, which lasted about three seconds and disappeared, "tingling out through the left ear." Four hours later a second attack occurred. The pain was stabbing in character, but after it had passed he felt quite all right. Such pains as these began to recur more and more frequently, becoming more severe, and would last as long as six, ten or twenty seconds. These attacks at first occurred only during the day, but as they increased in frequency and severity they came also during the night, awakening him suddenly from sleep. Five months after their onset they were occurring every ten minutes. He recognized that eating and swallowing, gargling, talking and having his throat examined all were prone to bring on the paroxysms of pain. At times these paroxysms came on independent of any such activity. Seven months after their onset there was a spontaneous remission for two days. The attacks soon attained their former severity and even increased so that he was in fear practically all the time, although he had no pain between the attacks. In the past year he had lost 45 pounds (20 Kg.) because of inability to eat and sleep. He had seen a number of physicians, who had prescribed various sedatives without relief.

He had had many sore throats during the greater part of his life. These were improved following an incomplete tonsillectomy about 1928. He had also been partially deaf in the right ear for many years. He smoked a great deal but had enjoyed general good health up to his present illness.

The patient was undernourished and of a wiry build. During the general physical examination he kept his mouth closed most of the time, saying very little and holding himself very still with muscles tense during a paroxysm of pain. His heart and lungs were within normal limits. He had an indirect inguinal hernia. The aural examination revealed a dull right ear drum which was sclerosed, with diminution of hearing in this ear. There was a marked deviation of the nasal septum.

Examination of the pharynx showed rather dry mucous membranes slightly atrophic with a chronic tonsillitis but no difference could be discerned between the right and left sides. When the left tonsil was pressed the paroxysm of pain would occur, demonstrating a definite so-called trigger phenomenon.

In view of this finding and the characteristic history together with the location and type of pain, the diagnosis of glossopharyngeal neuralgia was made.

The patient was given trichloroethylene to inhale three or four times a day. While using trichloroethylene he was able to get relief for as long as three or four hours at a time, and under this treatment he again was able to talk, chew and swallow. Likewise several hours of uninterrupted sleep could be obtained. His general health improved markedly, but because complete relief was not afforded he was anxious to undergo a surgical procedure for complete and permanent relief. August 30 an intraaural section of the ninth cranial (glossopharyngeal) nerve of the left side was performed by Dr. Gilbert Horrax and Dr. James L. Poppen through a left

From the Ear, Nose and Throat and Neurosurgical departments the Lacey Clinic.

suboccipital approach as suggested by Adson¹ and used by Dandy.² The postoperative course was entirely uneventful. The wound healed by first intention and he was immediately free from pain.

The areas marked in figures 1 and 2 illustrate the resulting anesthesia following section of the ninth nerve. His sense of taste was lost on the posterior third of the tongue on the left side. The pharyngeal muscles showed normal action. He was discharged from the hospital on the twelfth postoperative day and has remained free from pain until the present time.

CASE 2—Mrs. M. G., aged 72, a housewife, was referred to the clinic complaining chiefly of pain in the right side of the throat. Her present illness began suddenly in the fall of 1934. While she was eating a sharp pain of knife-like character shot through the throat. The pain is brought on by eating, swallowing or talking. The pain comes only during the day and does not interfere with her rest or sleep. In March 1935 the pain stopped without treatment and did not reappear until the latter part of August and has persisted since. Her general physical examination was negative except for changes associated with her age. Nothing could be found in the pharynx, and the two sides were practically identical. Swallowing a weak acetic acid solution would invariably bring on a paroxysm of pain. Following the paroxysm of pain her voice would be husky or hoarse for several minutes. The patient has been given trichloroethylene and as yet has not decided in favor of surgical treatment.

REVIEW OF LITERATURE

The first report of idiopathic glossopharyngeal neuralgia was published by Sicard and Robineau³ in 1920. They detailed three cases that were similar to the one recorded here. Their treatment consisted in peripheral division of the glossopharyngeal nerve, the pharyngeal branches of the vagus, and the branches of the cervical ganglion. In these cases pain was relieved.

In 1921 Harris⁴ reported two untreated cases of typical glossopharyngeal neuralgia. In 1923 Doyle⁵ reported four typical cases of glossopharyngeal neuralgia in one of which a gasserian ganglion operation was performed and later a peripheral section of the ninth nerve and the pharyngeal branches of the tenth nerve. In another the third division and the auriculotemporal branch of the fifth nerve were injected without relief.

Adson¹ reported four cases in 1924. Two of these patients were treated and relieved by peripheral nerve avulsion and section of the pharyngeal branches of the vagus. He described the technic for peripheral avulsion and for intracranial section of the ninth nerve, advocating the latter method to prevent recurrence, stating that it was no more formidable than the neck dissection. Heath⁶ was the first to take advantage of this route. However, his patient died of a postoperative pulmonary complication. Fay⁷ used this approach to the glossopharyngeal nerve in 1926 to relieve pain from carcinoma of the tongue and pharynx. Also Singleton⁸ reported two cases of glossopharyngeal neuralgia, one of which was treated by peripheral avulsion. In 1927 Davenport⁹ used intracranial section for glossopharyngeal pains which were later found to be due to an

epithelioma of the larynx infiltrating the pharyngeal wall. Also Goodyear¹⁰ reported an untreated case of glossopharyngeal neuralgia at this time.

In 1927 Dandy² was able to report two successful cases of intracranial section of the ninth nerve for true glossopharyngeal neuralgia, with permanent and complete cure without any unpleasant complications whatever. Dandy following this operation was the first observer to give accurate knowledge on the function and the sensory distribution of the ninth nerve and demonstrated that section of the vagus fibers to the pharynx was unnecessary to relieve the pain of glossopharyngeal neuralgia. He showed further that there was no observable motor function of the ninth nerve, the pharyngeal muscles being entirely normal after intracranial section of this nerve. The sensation of taste was found to be lost on the posterior third of the tongue on the operative side.

Dandy's report on this subject is unsurpassed in the literature. At the time of his publication he was able to collect but fourteen cases of true glossopharyngeal neuralgia, including the two cases of his own. Since this time further cases have been recorded, but the literature is by no means voluminous. In 1928 Hansel¹¹ recorded five untreated cases. In 1932 Keith¹² collected ten additional cases which were reported between 1928 and the time of his paper, adding three of his own. Cases also have been reported by Usadel,¹³ Jefferson,¹⁴ Reichert,¹⁵ Filatov,¹⁶ Chavany,¹⁷ Ball,¹⁸ Singleton¹⁹ and Peet.²⁰

The history and symptomatology of patients suffering from glossopharyngeal neuralgia are all very similar, practically the only variations being the duration of the disease and the frequency and duration of the sharp, shooting or burning pains in the throat. These pains, as a rule, become more severe and more frequent with time, but remissions at from a few hours to a number of years are frequently recorded. At the onset, as a rule the paroxysms are less frequent and may occur only during the day, but as time progresses sleep is disturbed by nocturnal attacks. The paroxysms of pain are brought on more frequently by swallowing than by any other one thing. However, talking, sneezing, yawning, coughing, laughing, examination of the throat and, in a few cases, manipulation of the ear may bring on an attack. While having pain the patient may sit transfixed with all muscles tense, or he may press his hand against the side of the neck and jaw.

DIFFERENTIAL DIAGNOSIS

Trigeminal neuralgia and glossopharyngeal neuralgia are alike in all respects except the location of the agonizing flashes of pain and the localization of the trigger areas which set off these paroxysms. The "trigger" areas in glossopharyngeal neuralgia include the pharynx—

geal wall, the tonsillar region, the base of the tongue and rarely the ear, while trigger areas of trigeminal neuralgia occur in the buccal mucous membrane and about the lips, nose and various areas on the face. When the first or second divisions of the trigeminal nerve are affected there should be little or no difficulty in the differentiation of these two neuralgias, but when the third division of the trigeminal is involved a little more care must be exercised to differentiate it from the ninth

cases, even when one seems typical, the examination should include a careful inspection of the larynx, the upper end of the esophagus, the palate, the nasopharynx and the posterior molar teeth and tonsils, because malignant conditions in these regions are prone to produce symptoms suggestive of glossopharyngeal neuralgia.

TREATMENT

Medical and surgical treatment are the two methods available in the treatment of glossopharyngeal neuralgia. The medical treatment has been referred to in each of the reported cases, and in our experience trichloroethylene has been the only drug that has really been efficient in giving a marked amount of relief from this condition. It is administered by the patient's inhaling from 15 to 30 drops from three to four times a day. The patient is instructed to lie down, drop the required number of drops into a gauze pad or kerchief, place it over the nose and inhale the vapor as long as he can smell the trichloroethylene. This inhalation is to be repeated three or four times a day.

The surgical treatment of choice is the intracranial section of the ninth nerve in the posterior fossa. The exposure makes it possible to observe this area for tumors, which have occasionally given rise to this neuralgia. Intracranial section prevents the recurrence of symptoms, which is possible following a peripheral section. Adson believes that intracranial section is no more formidable than the neck dissection to reach the glossopharyngeal nerve. The disadvantage of the periph-

Fig 1—Area of anesthesia Oct 23 1935. Stippling represents area of anesthesia following intracranial section of the ninth glossopharyngeal nerve.

nerve. In either neuralgia the pain may seem to spread beyond the distribution of the fifth or ninth nerves, but careful questioning will reveal the point of greatest intensity or the real pain to be in the area supplied by the affected nerve. Cocainization of the mucous membranes over the distribution of the ninth nerve will, as a rule, temporarily control the paroxysmal pain from this nerve. Peet²⁰ reports combined glossopharyngeal and trigeminal neuralgia in five cases in which he feels very positive about the correctness of the diagnosis. One of his cases is unique in that there was a glossopharyngeal neuralgia on each side, but the right and left sides were never affected simultaneously and the patient had also a left trigeminal neuralgia which had been relieved by operation previous to the onset of the glossopharyngeal neuralgia.

Weisenburg²¹ was apparently the first to direct attention to the resemblance of unusual pain in the distribution of the ninth nerve to the major trigeminal neuralgia. The pain persisted after operation with partial removal of a gasserian ganglion, and during the last year of the patient's life a "trigger" area was present at the base of the tongue. The pain, however, was not idiopathic but due to a tumor in the cerebellopontile angle. For this reason Dandy stressed the importance of intracranial section of the ninth nerve so that this region might be visualized at the time of operation.

Earlier in this paper a case was referred to in which the glossopharyngeal nerve was cut and the pain was later found to be due to a carcinoma growing from the larynx and involving the pharynx. Certainly in all

Fig 2—Area of anesthesia Oct 23 1935.

eral section and avulsion is that the condition may recur, and secondly that the intracranial region cannot be visualized. An alcohol injection is not feasible because of the small size of the nerve and its very close relation to the vagus, the jugular and the hypoglossal nerve. It is remarkable that the patient following intracranial section of one glossopharyngeal nerve is not conscious of any paresthesia or discomfort whatever from the loss of sensation of the nerve.

²¹ Weisenburg T H. Cerebellopontile Tumor Diagnosed for Six Years as Tic Douloureux. The Symptoms of Irritation of the Ninth and Twelfth Cranial Nerves, J A M A 54: 1600 (May 14) 1910.

ABSTRACT OF DISCUSSION

DR J JAY KEEGAN, Omaha The possibility of relief of intolerable spasmodic pain in the throat by intracranial section of the ninth or glossopharyngeal nerve is worth knowing both because of necessity of differentiating the pain of glossopharyngeal neuralgia from trifacial neuralgia and because of the misdirected nose and throat surgery which will not relieve the condition. The term neuralgia, like rheumatism, is used rather freely by both physicians and the public to denote pain of great variety of character and origin. Pain that is constant aching or throbbing should not be called neuralgia. The essentials of neuralgic pain are intermittent, sharp, shooting pain which is brought on by some movement or irritation of a trigger zone. In glossopharyngeal neuralgia this trigger zone is in the tonsillar region and can be relieved temporarily by cocaine anesthetization of this region. The pain radiates to the angle of the jaw and may be confused with trifacial neuralgia. Added differentiation may be obtained by procaine hydrochloride injection of the inferior maxillary branch of the fifth nerve, which will not relieve glossopharyngeal neuralgia. A condition closely related to glossopharyngeal neuralgia but perhaps more of a

Fig 3—Healed incision ten days after operation

neuritis, is the localized pain that occasionally develops after radium treatment of a tumor in the lateral pharyngeal wall. It is recognized that the dense scar which develops from intense radium treatment may so involve nerve endings that a very painful neuritis follows. This applies to the face and the cervix of the uterus as well as to the throat and may necessitate some attempt at surgical relief. I have had two such cases very similar to glossopharyngeal neuralgia in which section of the ninth nerve intracranially was done to obtain relief. Likewise in cases of extensive malignant involvement of the face and throat intracranial section of both the fifth and ninth nerves may be necessary to gain some relief from excruciating pain. It should be emphasized however that sensory root section can be expected to relieve only sharp shooting pain of neuralgic character and that continuous aching or boring pain probably from tumor pressure or infection cannot be entirely relieved by nerve section. The intracranial surgical approach to the ninth nerve is not particularly difficult or serious in the hands of one skilled in neurosurgery. The operation can be done under local anesthesia and advanced age in itself is no contraindication. The patient should tolerate the operation if his health permits reasonable activity. The ninth nerve is identified below the eighth nerve as a small filament at the upper border of the tenth nerve. It is so small that doubt cannot help but be felt that its section will relieve such an extensive painful syndrome.

DR FRENCH K HANSEL, St Louis It is interesting that although trigeminal neuralgia has been recognized as a definite clinical syndrome for more than 150 years, glossopharyngeal neuralgia had not been reported previous to 1920. The pain occurring in these two types of neuralgia is typical and characteristic and there should be no difficulty in diagnosis. It is noteworthy that, in some cases of glossopharyngeal neuralgia exacerbations may be excited by irritation of the auricle. Although other otolaryngologic conditions may be associated with glossopharyngeal neuralgia, no etiologic association is likely, but they may influence the trigger mechanism. For example, I had the opportunity to observe a patient who developed typical attacks of glossopharyngeal neuralgia during the treatment of a chronic otitis media. An analysis of the clinical history revealed the fact that the patient had had similar attacks fifteen years previously. He had experienced a period of relief lasting as long as thirteen years and before the time he was being treated for chronic otitis media he had been free of pain for four years. As a result of the treatment of the middle ear, the trigger mechanism was stimulated and the patient again began to have attacks of neuralgia. The patient was eventually relieved of all pain by intracranial section of the glossopharyngeal nerve.

DR WALTER B HOOVER, Boston I wish to thank Dr Keegan for his discussion and the mention of the operative procedure. I owe a great deal to Dr Hansel because he brought this condition to my attention. I have been looking for it during the past eight years since Dr Hansel called my attention to it and I was able to find two cases only in the past year. Glossopharyngeal neuralgia is relatively infrequent but it is much more frequent than is recognized.

PERMANENCE OF CURE FOLLOWING RUPTURED DUODENAL ULCER

DONALD GUTHRIE, MD

SAVRE PA
AND

ROBERT F SHARER, MD
CHICAGO

The acute perforation of a duodenal ulcer followed by the immediate emptying of gastric or duodenal contents into the abdominal cavity confronts the surgeon with two problems: first and foremost to rescue the patient from impending death and, second, to restore permanently symptom-free digestive function. Surgeons are agreed that immediate surgical intervention is imperative in all but moribund patients and that in few other abdominal emergencies is the time factor of greater importance.

The choice of operative procedure, however, has long been a subject of considerable interest, outstanding surgeons disagreeing as to the type of operation most likely to accomplish the ideal result.

The conservative school believes that the operation of simple closure of the ulcer will lower the operative mortality to a minimum and will accomplish a lasting cure in the majority of those who recover only from 10 to 20 per cent requiring a later gastro-enterostomy for obstruction.

A small number of large calloused ulcers, impossible of closure without producing obvious obstruction to the duodenum, require an immediate gastro-enterostomy. Trout¹ McClure² Fleming³ Dineen⁴ Finney⁵ Urru

tia,⁶ and the senior author are among this conservative group. The majority of final results published include both gastric and duodenal ulcer and it is difficult to separate the two groups, but approximately 60 to 65 per cent of those with simple closure were reported cured from 10 to 15 per cent received delayed gastro-enterostomy for obstruction and the remainder required medical management for continued distress.

A less conservative school, ably championed by Deaver⁸ believes that closure of the ulcer with immediate routine gastro-enterostomy will reduce the mortality and morbidity and remove the necessity of a second operation for obstruction. This group believes that the gastro-enterostomy will aid in the healing of the closed ulcer or accompanying ulcers and will prevent postoperative leakage, hemorrhage or a second perforation. These complications occur however, in only a small percentage of simple closures and have been reported in patients receiving primary gastro-enterostomy. The published mortality rates for this double procedure are not comparable with those of simple closure as it is employed in the main in early cases, although Deaver's mortality rate of 7.5 per cent for his entire series is extremely low. Such additional surgery on a critically ill patient must carry a mortality of its own in any but the most gifted hands. Lewisohn⁹ reports gastrojejunal symptoms in 34 per cent of his cases, while Dineen, Brenner¹⁰ and Urrutia report continued ulcer distress in from 25 to over 50 per cent.

Pyloroplasty has its advocates but Hinton¹¹ found that, of nine of the Horsley type followed, only two were symptom free. White and Patterson¹² found that, of seven pyloroplasties performed, six patients lived but all had continued distress, attributed to the too rapid emptying of the stomach. McDonald,¹³ however, advises pyloroplasty under twelve hours.

A recent more radical school of foreign origin has accepted partial gastrectomy as the operation of choice. Graves,¹⁴ in his survey of the German clinics, mentions the fact that 60 per cent of perforated ulcers occur in strong, heavy-eating laborers, often with hyperplastic or atrophic stomachs and in from 20 to 50 per cent of whom multiple ulcers are found. Gastro-enterostomy was formerly performed on these patients with a low mortality but a high incidence of hemorrhage, leakage and perforation of accompanying ulcers, with the result

that, in recent years, partial gastrectomy has been widely adopted. Finsterer,¹⁵ however, still advises simple closure for acute perforations of both the duodenal and the gastric type. The mortality in partial gastrectomies has remained low in early selected cases in the best clinics, but long-term follow-up studies are lacking and it is doubtful whether the gastric disease is comparable to that found in this country. Lewisohn, however, found 50 per cent multiple ulcers in gastric resections for ulcer and in reporting eighty-eight cases of perforated ulcer with a mortality of 31 per cent, stated that 39 per cent of the cases followed were not cured by simple closure, with or without gastro-enterostomy.

The operation of choice in these cases is therefore still in question and it was for this reason that the following study of our own series of seventy-eight cases of acute perforated duodenal ulcer was made.

Four of these patients were operated on outside the hospital by the senior author and seventy-four acute perforated duodenal ulcers have been treated in the Robert Packer Hospital over a twenty-six year period that ended in April 1936, and excluding sixteen acute perforated gastric ulcers also all perforations of the subacute or chronic variety of the duodenum or stomach. These occurred among 112,136 admissions, 69,876 of which were to the surgical service, being one in 1,515 general admissions or one in 944 surgical admissions. But two of our patients were females and the ages ranged from 18 to 85, the average being 44 years.

A previous history of ulcer distress was usually obtained and the abrupt onset of excruciating epigastric pain, fixing the patient in a jack-knife position from which he could be straightened out only after overcoming his strenuous objections, was of great diagnostic value. One young man however, walked into the clinic with symptoms referable to the right lower quadrant, the latter being not uncommon and confusing the condition with acute appendicitis. Vomiting, occurring but once or twice, was present in about 50 per cent, five vomiting blood. A leukocytosis with a high differential count was nearly always present a few hours after the onset.

A tense boardlike rigidity and general tenderness, not equaled in any other abdominal catastrophe, was constant, the breathing being of the costal type. In late cases, however, the picture changed to one of general peritonitis with alleviation of the intense pain and rigidity. Pneumoperitoneum, determined by correct fluoroscopic examination, was of distinct value in many cases, and Singer and Vaughan¹⁶ maintain that

Fig. 4—Eight years after simple closure for acute perforated duodenal ulcer

it is effective in 86 per cent of their cases proved by operation. Figures 1, 2 and 3 are reproductions of roentgenograms of three cases of perforated ulcer revealing the air pockets beneath the diaphragm.

The treatment employed in this clinic has been one of simple closure, a gastro-enterostomy being performed at a later date only if obstruction developed. Four patients, however, required a gastro-enterostomy at the first operation because of obvious obstruction

Fig. 5—Nine years after simple closure

of the duodenum. It is surprising, however, how much the duodenal lumen may be encroached on without producing obstructive symptoms. The ulcer in each case was closed by through and through sutures of intestinal chromic catgut and inverted by a second row of catgut or a purse-string of linen. The defect was protected by a tab of gastrohepatic omentum.

Excluding six patients entering the hospital in a moribund condition and dying without operation, there were fifteen patients who succumbed giving an operative mortality of 20.8 per cent. Postmortem examinations were performed in every instance, the results appearing in table 1.

Five patients, averaging eighteen hours' delay, drained both in the epigastrium and in the pelvis, died of general peritonitis. While it is true that, as the result of the action of hydrochloric acid, the contents of the stomach are practically sterile from three to four hours after ingestion, many of these patients had taken fluids or food at a shorter period before perforation. Deaver reported a positive culture in eleven of thirty-four cases, while Brutt¹⁷ obtained a positive culture in 74 per cent of a six to twelve hour group and in 93 per cent after twelve hours, 112 patients having cultures taken and *Streptococcus haemolyticus* and *viridans*, *Bacillus coli* and *staphylococci* being

Fig. 6—Nineteen years after simple closure

obtained. Blalock¹⁸ has shown that the injection of infected bile and pancreatic juice into the peritoneal cavity of dogs is much more lethal than the uninfected juices, also that the combination of the two is more deleterious than either alone. Trout has recently emphasized the importance of poor oral hygiene. Hinton, Dineen and many others have listed general peritonitis as by far the leading cause of death.

Three patients, operated on within an average of five hours after perforation, died of bowel obstruction at the site of drainage tubes, the former custom being to drain the pelvis and upper abdomen in all cases. One patient with five hours' delay died of abdominal abscesses, in spite of drainage in both the epigastrium and the pelvis, while one, with nine hours delay, drained only in the pelvis and died of subhepatic abscess and empyema. These collections of pus were drained without success.

At present it is our custom to close without drainage all cases of less than eight hours' delay unless poor

¹⁶ Vaughan R. T. and Singer H. A. *Surg. Gynec. & Obst.* 49: 593 (Nov.) 1929.

¹⁷ Brutt, H. quoted by Fleming¹.

¹⁸ Blalock Alfred. *Surg. Gynec. & Obst.* 61: 20 (July) 1935.

oral hygiene or extensive soiling is present. It is probable that the peritoneum can destroy the inhibited bacteria present in the early case, once the leak is stopped, with avoidance of the danger of bowel obstruction. The bacteria in the late case, however, have regained their vigor, as shown by the high percentage of positive cultures, and drainage above and below is indicated.

Fig 7—Two years after simple closure.

One perforation occurred in a patient who was in the hospital under treatment for severe massive hemorrhage from duodenal ulcer and on immediate operation, the abdomen was found filled with blood, death ensuing in a few hours in spite of transfusions. In one case the skin sutures and silkworm retention sutures were removed by mistake on the seventh day after operation, followed by wound disruption and death.

Bilateral parotitis led to death in one case on the tenth postoperative day. Following this experience, careful oral hygiene and the chewing of gum after operation were adopted in the hospital.

TABLE 1—Causes of Death in Fifteen Cases

| Cause of Death | Cases | Average Hours Delay |
|--------------------------------|-------|---------------------|
| General peritonitis | 5 | 18 |
| Bowel obstruction | 3 | 5 |
| Lobar pneumonia | 2 | 15 |
| Abdominal abscess | 1 | 5 |
| Subhepatic abscess and empyema | 1 | 9 |
| Hemorrhage and shock | 1 | 1 |
| Bilateral parotitis | 1 | 20 |
| Wound rupture | 1 | 1 |

It is important to note that not a single instance of reoperation, leakage of the ulcer or perforation of a second ulcer was present in this series. It is difficult to see therefore, how a more radical procedure, such as gastro-enterostomy or a partial gastrectomy, could have reduced this primary mortality. Table 2 shows the mortality.

Ten delayed gastro-enterostomies were performed without a death, while two of the four primary cases were fatal. In the delayed cases obstruction usually developed within a few months but Dineen has empha-

sized the fact that obstruction may be the result of pylorospasm initiated by nervous upsets which will respond to medical management.

A careful follow up, often including roentgenographic examination, was made on all but three of the fifty-seven patients who recovered, the results appearing in table 3.

The end results over a twenty-six year period of conservative treatment were as follows. One patient in five with simple closure died while, of those who lived, less than one in five required delayed gastro-enterostomy for obstruction. Of the remainder who

TABLE 2—Mortality

| | Cases | Deaths | Percentage |
|------------------------------|-------|--------|------------|
| Duodenal ulcers | 78 | 21 | 26.9 |
| Operative cases | 72 | 15 | 20.8 |
| Simple closures | 68 | 13 | 19.1 |
| Primary gastro-enterostomies | 4 | 2 | 50 |
| Delayed gastro-enterostomies | 10 | 0 | 0 |

lived, with merely a simple closure of the perforation, over 95 per cent of the patients followed are well today or were until their death from unrelated causes. The ten patients who were reoperated on for obstruction all recovered, only one of the nine followed having symptoms and one reported dead from cancer.

Figures 3 to 10 are reproductions of roentgenograms of seven patients symptom free from two to twenty-one years after simple closure.

SUMMARY

Acute perforated duodenal ulcer is of rare occurrence but must be kept in mind.

Fig 8—Three years after simple closure.

The importance of a correct diagnosis and immediate surgical management are stressed, because in no other acute abdominal emergency is the time factor of greater importance.

Postmortem examination, which was carried out in every operative case that ended in death, gave no indication that primary gastro-enterostomy or a partial

gastrectomy would have made a reduction in the operative mortality

Drainage of the abdomen increases the hazard of bowel obstruction and may well be omitted in the majority of cases less than eight hours old

In this group of patients with simple closure who did not develop obstruction, over 95 per cent of those

Fig 9—Two years after simple closure

followed remained well the perforation perhaps destroying the ulcer site to a degree approaching that of the cautery

Delayed gastro-enterostomy may be safely performed on those developing obstruction, the great majority remaining symptom free

TABLE 3—End Results in Fifty-Seven Cases

| | |
|---------------------------------|---|
| Primary gastro enterostomy | 2 well |
| Simple closure | 41 well 2 ulcer distress 2 unchecked |
| Plus delayed gastro enterostomy | 7 well 1 ulcer distress 1 cancer ? 1 unchecked |

From a review of the complete autopsies and a nearly complete follow up in this long term series of cases, it would appear that simple closure should be the procedure of choice in the majority of perforated duodenal ulcers

ABSTRACT OF DISCUSSION

DR. HARRY KERR Washington D C Opinions as to the ultimate results in perforated duodenal ulcer are undergoing a change Two or three decades ago perforation was considered as almost curative Indeed Gibson said in 1916 that a perforation was often a blessing in disguise to the ulcer sufferer Careful studies from larger city hospitals where early cases are more commonly seen showed a cure in only 60 or 65 per cent. This resulted in advocacy of procedures designed to cure the ulcer as well as the perforation Deaver as Drs Guthrie and Sharer have said advocated gastro-enterostomy Other

surgeons advocated pyloroplasty and some even gastric resection in acute perforated duodenal ulcer The bulk of evidence, however, still shows that the simplest operation to fit the individual case is the procedure of choice The perforation is an emergency and demands immediate operation The primary consideration is the closure of the perforation and the simplest way is best A single continuous suture placed at right angles to the axis of the bowel and enfolding the perforation will reduce the lumen much less than a suture placed parallel to the axis and will reduce the number of cases of primary gastro-enterostomy A single suture that is continuous and is well placed in the fibrous coat if subject to any tension will tighten and make the closure even firmer In the last twenty years twenty-three patients with acute duodenal perforation have been operated on at the Garfield Memorial Hospital in Washington. The immediate operative mortality was 8 per cent A follow up was obtained in twenty cases of the twenty three Thirteen of these were symptom free or almost symptom free with no indication of recurrence of the ulcer from one to fourteen years after operation In other words of our small group of acute perforated duodenal ulcers, 65 per cent showed cure of the ulcer following perforation The authors' figure of 95 per cent well after closure of acute perforation brings us back to the dictum of the past, that a perforation often cures an ulcer

DR EDWIN G RAMSDALL, White Plains, N Y This presentation emphasizing conservative treatment is most timely On the question of simple closure versus closure with added gastro-enterostomy, a few years ago, in response to a question naire, Dr Guthrie received replies from about 150 American surgeons Fourteen per cent added a gastro-enterostomy as a routine at the time of closure, 42 per cent never added a gastro enterostomy, and 41 per cent occasionally added a gastro enterostomy Drs Guthrie and Sharer have told of four cases

Fig 10—Twenty-one years after simple closure

in which at the time of the perforation on account of the presence of a probable obstruction they found it necessary to do a primary gastro-enterostomy They have illustrated the point that these cases should be individualized I have a follow up on sixteen consecutive patients on whom I operated at the White Plains Hospital On eleven a simple closure was done and on five a gastro-enterostomy was added Thirteen were operated on within six hours of perforation two within twelve hours and one at forty-two hours after perforation All recovered One required a secondary gastro enterostomy within a

year. One developed carcinoma four years after perforation. This patient has just had a partial gastric resection. The interesting problem is presented as to whether or not carcinoma was present in the edematous mass at the pylorus at the time of the perforation four years ago. Dr. Fwing has recently stated that he thought it was an error to assume that carcinoma of the stomach is always of short duration. Perhaps carcinomatous cells may remain at the site of a gastric lesion for a longer period than has been considered probable. Whether this patient had carcinoma four years ago or whether he developed it during the interval may be questioned. At any rate the possibility of carcinoma is another indication for the individual consideration of each case.

DR. W. T. COUCHLIN, St. Louis. I have never performed a gastric resection or a gastro-enterostomy at the time I had to deal with a perforation. Closing of the perforation has been my only effort. There was one case in which the tissues were so edematous that I couldn't turn the perforation in. It did very well with placing the omentum over it and stitching it around the perforation. The patients afterward have been of the same belief that some of the doctors are, namely, that one need not be concerned about them. I have found that is not so and that it has been necessary to operate on about half of them afterward for one difficulty or another. One patient died unoperated on. He said that he had had operation enough the first time. He bled to death. A point in diagnosis is the differentiation from angina pectoris. I made two such errors once, mistaking angina pectoris for an abdominal catastrophe and once mistaking an abdominal catastrophe for angina pectoris. The presence of free air under the diaphragm is diagnostic of perforation.

DR. ROBERT F. SHARFF, Oak Park, Ill. In conclusion I wish to state that our feeling in this surgical problem is as follows. If gastro-enterostomy is to be performed at the first operation, with simple closure it must accomplish one of two things: it must either reduce the primary mortality or improve the end results. In our mortality statistics there were fifteen deaths. In only seven of the fifteen could death be attributed to abdominal sepsis and most of these septic deaths were cases of long delayed operation in which peritonitis would be expected. Three of the nonseptic deaths were the result of bowel obstruction at the site of drainage tubes which gastro-enterostomy would not have saved. Another patient died of separation of the wound after the intern removed all sutures on the seventh postoperative day. Two patients died of pneumonia, one of bilateral parotitis, and one of shock following perforation of a bleeding ulcer, the abdomen being filled with blood. Certainly gastro-enterostomy would not have saved any of these patients. The important points in this complete autopsy study are that there was no evidence of later hemorrhage, no evidence of leakage of the closed ulcer, and no perforation of a recurrent ulcer. From these observations we do not believe that a gastro-enterostomy performed at the time of the original operation would have reduced the primary mortality. We made a follow-up study of end results on all but three of the fifty-five patients who lived. Only ten required a later gastro-enterostomy for obstruction and the operations were not followed by death. The follow-up on nine of these patients and forty-three of the remaining forty-five revealed all but three patients well. The latter still had ulcer distress. There were 95 per cent of cures. The patients in the well group were maintaining their weights and were actively at work, most of them paying little attention to their diet. X-ray films taken of a considerable number showed normal functioning stomachs although a scarred duodenum. Apparently the perforation destroyed the active seat of the ulcer.

'A Lean Horse for a Long Race'—In general young people who are below the standard weight for their height as of age 30 will do well to fatten themselves up to that standard, and older people do well to hold their weight down to the same standard, remembering the old adage: A lean horse for a long race.—Sherman H. C. Food and Health, New York, Macmillan Company, 1934.

ACUTE MESENTERIC ADENITIS

CHARLES STANLEY WHITE, M.D.

AND

J. LLOYD COLLINS, M.D.

WASHINGTON, D. C.

Acute inflammation of the mesenteric lymphatic glands has not been recognized as a medical or surgical entity but in the absence of much desirable data the symptoms or the disease, as the case may be, is usually designated by those few who have described it as acute mesenteric adenitis. This is not to be confused with the tuberculous adenitis that is often seen as a part of the picture of tuberculosis of the gastro-intestinal tract and peritoneum.

For a number of years I have been puzzled by having in my practice cases that appeared to be acute appendicitis clinically, but at operation the appendix did not seem pathologically consistent with the clinical picture. To be sure, the appendix was red, but it was never gangrenous or ruptured. A small quantity of clear or slightly cloudy fluid was found in the peritoneal cavity particularly adjacent to the cecum. The cecum and small bowel were abnormal only in the congested appearance of the vessels. The outstanding pathologic condition was found in the mesentery of the distal three feet of the small intestine. Here the glands were conspicuous by their number and size. Normally glands can neither be seen nor felt in this mesentery, but in these so-called cases of acute appendicitis the glands varied in size from 1 to 3 cm in diameter, were firm, were a distinct pearly gray, and numbered from three to a dozen or more. None of the glands were suppurating or gangrenous, and any one could be easily enucleated.

One procedure in such cases was to remove the appendix and wonder what was the relation between the glands, the appendix and the clinical signs and symptoms. All the patients recovered after two or three days of declining fever, and no drainage was employed in any case.

Several times I have removed a few of the mesenteric glands and sent them to laboratories for study. They have all failed to develop a growth in various mediums and the sections have shown lymphoid hyperplasia. They were definitely not tuberculous.

During the years 1934 and 1935 I had sixteen cases as described, which I have labeled acute mesenteric adenitis. There seems to be a seasonal periodicity in their appearance, not unlike an epidemic of a communicable disease. There is much information to be desired in reference to the cause and diagnosis of this disease. The sum total of present knowledge is fragmentary, but it may be possible to assemble a complete account of the disease if the various internists and operators add their bit to what there is. With the object of stimulating interest in this subject I am detailing a composite case and bringing up to date all the material contributions that were available.

A cross section of the cases I have seen would give a history approximately as follows:

A child, aged 12 years, without previous history of recent illness, gastro-intestinal disorder, sore throat or exposure to contagious disease, is disturbed by abdominal pain. The pain is rather severe and constant but not colicky. It is rather general but is more marked

in the lower than in the upper part of the abdomen. There is generally an elevation of temperature from 102 to 103 F being rather the rule, with corresponding acceleration of the pulse and respiratory rate. Diarrhea is rarely present, and constipation is the rule. Nausea is present in nearly all cases, and vomiting has not been persistent and usually ceases after the stomach is entirely emptied. Foul vomitus has not been encountered.

The physical examination shows a slightly distended, tympanic abdomen, generally tender and resistant to pressure. While tenderness is marked in the lower right quadrant it is also conspicuous by its presence in the lower left quadrant. The abdomen is uniformly distended but not to an extreme degree. The physical examination of the throat and chest has been, in my experience, uniformly negative for gross pathologic changes.

The blood counts have shown for the most part moderate leukocytosis (from 8000 to 14000) but a

Acute mesenteric adenitis showing typical destruction of hyperplastic glands in the mesentery of the ileum

high percentage of polymorphonuclear neutrophils (from 80 to 95 per cent). The urine shows neither pus cells nor albumin.

With such a history of an illness of forty-eight hours or less in duration, scarcely any other diagnosis than acute appendicitis can be entertained, and the patient forthwith is admitted to a hospital and the appendix is removed without delay. With present knowledge of the fulminant nature of appendicitis, especially in children, any other treatment than surgical seems illogical.

At the operation as I have stated in an earlier paragraph the appendix appears in the role of the innocent bystander and promptly meets the usual fate of that individual.

Such is the history and termination of these cases as I have seen them. There is something decidedly unsatisfying in the entire performance in that (1) the diagnosis was inaccurate, (2) it is very possible the patient would have recovered without operation, (3) the pathologic condition remains unexplained and (4)

the error in diagnosis in all probability will be repeated, as no differential diagnosis can be established with the present inadequate data.

I have found a number of references to this disease (if I may so term it temporarily) by a score or more of contributors to the literature in this country, in England and on the continent, but no one has traced the inciting agent, if one exists. A possible exception may be made in the paper of Goldberg and Nathanson¹ of Chicago, who reported nineteen cases studied rather carefully. I shall consider their cases later.

Struthers² of Edinburgh seems to have been the first to call attention to this disease, in a paper in 1921 entitled "Mesenteric Lymphadenitis Simulating Appendicitis." He leaned to tuberculosis as the underlying cause but states that it is far from conclusive. Three of the four cases reported were definitely not tuberculous.

Leonard Freeman³ of Denver in 1923 writing on this subject, satisfies himself that the adenitis is due to absorption from the intestinal canal and further suggests that it follows the ingestion of contaminated milk or other foods. He offers the theory that it is of a tuberculous nature but strictly a bovine type guinea-pig inoculations, however, were not convincing.

Speese⁴ in 1929 devoted considerable space to the discussion of the etiology and suggested

(a) Stasis of fecal current with increased virulence of the organisms in the ileum

(b) Inflammatory processes with abrasions and small abscesses in the bowel in this region with secondary infection of the glands

(c) Ulcerations in Peyer's patches, with secondary gland involvement

Wilensky and Hahn⁵ in 1926 made the statement that the mesenteric lymph node of the ileum is never seen in the usual types of acute appendicitis, and since the appendix was not involved in their cases of mesenteric adenitis there is no clinical relationship between the two conditions.

I found approximately twenty other references to the subject, all very much of the same tenor. Wagner reported a case he ascribed to trauma. The consensus is overwhelmingly against a tuberculous invasion.

Goldberg and Nathanson,¹ in an analysis of their nineteen cases conclude that the disease can be laid at the door of the hemolytic streptococcus because the organism was found in all the throats of which cultures were taken, eight out of nineteen, and add that "the same organism has been isolated from a small percentage of the nodes removed and studied." Since such a study was made in but one case, this leaves much to be desired in fixing the causal relationship. I do not attach much importance to the presence of streptococci in the throat in connecting up the evidence. The authors are in accord with practically every observer in exonerating the appendix and agree with the general opinion that a prompt exploratory operation should be done, as a differential diagnosis is quite impossible. They very properly take the stand that this is a safer procedure as a surgical principle than to treat such a case medically.

5 Wilensky A O and Hahn L J *Ann Surg* 83:812 (Jun) 1926

My experience has been interesting, but so far with rather negative results. I have not consistently found an organism, and the microscopic sections have been without differential features. I can state that it is not tuberculous and is not associated with appendicitis or with any microscopic characteristic changes in the intestine or mesentery that offer a promising clue of the disease. But this is not new.

One pathologic report by Dr. Earl B. McKinley⁶ offers a ray of hope. He said:

The lymph nodes in the case of E. E. have just been brought to my attention and upon examination I find no inclusion bodies in any of the cells which would be pathognomonic of virus infection, such as influenza. However, only about half of the virus diseases are associated with inclusion bodies and these have never been described as yet for influenza. One might try to infect ferrets with emulsions of mesenteric lymph nodes from such cases as this and in that way demonstrate the presence of the virus.

It requires considerable temerity on my part to suggest poliomyelitis or any other virus disease as a cause of mesenteric adenitis, in view of my incomplete study, but I believe that it is entitled to consideration. The conception of poliomyelitis has changed somewhat in recent years, and, while it may not fit into the symptomatology of mesenteric adenitis, one should consider for a moment the following statement by Burrows:⁷

It seems quite evident, therefore, from all available evidence at the present time that the primary lesions of the poliomyelitis are not in the central nervous system. Poliomyelitis is probably a misnomer as it is applied to the disease as a whole. It is merely a complication of a widespread infectious disease. The disease is not a primary disease of the central nervous system, it is a disease of the lymphatic systems of the body. The lesions presented are not of the kind in which pus appears early, but the lesion is rather that of an acute hyperplastic lymphadenitis. The pathologic picture in all of the fatal cases was a general lymphoid hyperplasia, which was most marked in the solitary follicles of the gastro-intestinal tract, Peyer's patches and the mesenteric lymph nodes.

He further states:

As Leake clearly pointed out, the systemic changes that are present in all cases are fever, headache and gastro-intestinal disturbances. The latter disturbances, which have been noted most often, are constipation and slight distention.

The other probable common virus disease is influenza. One hears much about "gastro-intestinal flu," but some members of the profession are skeptical of its existence and believe that the term is merely a camouflage for ignorance. The majority of country physicians, and I still believe they are the keenest observers, have no doubt that influenza of the gastro-intestinal tract is as much of a medical entity as pneumonia.

The pathology of influenza is not definitely known except in the fatal cases, and here a lung complication usually predominates. I certainly have little or no information about the pathologic changes in the gastro-intestinal tract.

Earl B. McKinley,⁸ in discussing the recent St. Louis epidemic of poliomyelitis, stated:

A study of the epidemiology and character of these various epidemics brings to mind again the possibility of their relation to epidemic influenza of probable filtrable virus origin, which, in some epidemics, may be of gastro-intestinal nature, in others,

upper respiratory, and possibly in others, one or both of these clinical pictures with the predominating effects soon after onset manifested in the central nervous system, the pathology being that of an encephalitis. The clinical history of this disease, the lack of discovery of the true etiological agent over these many years, permits at least the raising of the question again as to its possible specific relation to epidemic influenza, most probably caused by an ultramicroscopic virus.

I admit my failure to discover the cause of mesenteric adenitis and have substituted suggestions for facts. It is my hope that the profession may have the time and opportunity to write the last chapter, based on further laboratory study.

SLOW CARBON MONOXIDE ASPHYXIATION

A NEGLECTED CLINICAL PROBLEM

HARVEY G. BECK, M.D.

BALTIMORE

Although much has been written on the subject of acute carbon monoxide poisoning, there is a dearth of literature on chronic carbon monoxide poisoning. This may be attributed to the fact that there is no unanimity of opinion as to whether frequent exposures to sublethal amounts of the gas over a considerable period of time causes any clinical phenomena or pathologic changes. Some authoritative textbooks on medicine either do not recognize the existence of chronic carbon monoxide poisoning as a clinical entity or lead one into doubt and pass the matter over with a mere reference to the subject.

Because of this prevailing doubt, I have critically studied from the standpoint of symptomatology and clinical manifestations a series of ninety-seven patients who were repeatedly subjected to sublethal doses of carbon monoxide, at varying intervals over prolonged periods. The results of these studies, as well as those which I¹ previously reported, seem to furnish ample data on which, considered as a result of slow carbon monoxide asphyxiation, a definite clinical entity can be established.

Carbon monoxide as a cause of accidental and suicidal deaths in the United States ranks second to automobile accidents. The latter are responsible for about 36,400 deaths annually and nearly a million injuries, entailing an estimated financial loss of billions of dollars. Unfortunately, no comprehensive statistics of deaths resulting from carbon monoxide poisoning are available to make a comparison of these two great hazards. However, in New York City, where reliable statistics have been recorded, there were 5,289 deaths during a five year period, 1928-1932. This incidence of over 1,000 deaths a year has been exceeded by only a comparatively small margin resulting from highway accidents with an average of 1,400 deaths a year.

Reasoning by analogy, I concluded that no noxious gas so potent when inhaled in atmospheric dilutions of 1 per cent or even less as to cause almost instantaneous death can be incapable of producing symptoms if inhaled in lesser concentration over a longer period of time.

Read before the thirty-seventh annual meeting of the American Therapeutic Society, Kansas City, Mo., May 8, 1936.

Neither time nor space permits of a discussion of the various sources of carbon monoxide gas or of its chemical and physical properties except to state that the gas is colorless, odorless, tasteless, nonirritating and nontoxic from a chemical point of view. The chief property on which the injurious action depends is its extraordinary affinity for hemoglobin, which is about 300 times greater than that of oxygen. This affinity results in the replacement of the oxygen in the hemoglobin molecule by carbon monoxide, inducing a state of anoxemia. Thus the symptoms produced are not directly due to carbon monoxide but indirectly to anoxemia. For this reason the term "chronic carbon monoxide anoxemia" would designate the true nature of the condition better than chronic carbon monoxide poisoning, as the latter is not only a misnomer but actually misleading.

The symptoms therefore, whether in the acute or chronic form, are identical with those occurring in other anoxic states, as, for example

1 Those due to low oxygen pressure in the arterial blood resulting from low oxygen pressure in inspired air (altitude) or mechanical interference with oxygen absorption (pulmonary edema, emphysema, bronchial asthma)

2 Those due to diminished oxygen-carrying capacity of the hemoglobin (anemia, methemoglobinemia, carbon monoxide)

3 Those due to impeded blood flow through tissues (shock, hemorrhages, cardiac failure, Raynaud's disease)

4 Those due to poisoning of tissue cells with consequent failure to utilize sufficient oxygen (cyanide, alcohol)

Bancroft² designated these forms as anoxic, anemic, stagnant and histotoxic anoxias respectively. All these conditions manifest certain symptoms in common because of insufficient oxygen to cause normal oxidation. The human organism as a whole cannot withstand the complete withdrawal of oxygen longer than a few minutes, whereas isolated tissues may recover after the complete withdrawal for several hours.

Structures that demand a rich blood supply, as the central nervous system and the heart muscles, are particularly susceptible to the effects of anoxemia. As a result the dominant symptoms of carbon monoxide anoxemia are referable to these organs. The symptoms produced naturally depend on the amount and rate of absorption of carbon monoxide by the blood and are governed by the amount of gas contained in the air inhaled, the temperature and humidity of the atmosphere, and the physical activity, general health and susceptibility of the individual exposed.

An atmospheric mixture containing 0.01 per cent or less of carbon monoxide may be inhaled indefinitely without producing symptoms. However, a mixture containing 0.05 per cent is sufficient to produce symptoms in the course of several hours, whereas a mixture of from 0.1 to 0.2 per cent causes severe symptoms dangerous to life, and a 1 per cent mixture results in almost instantaneous death.

In other words, the severity of the symptoms produced is in accord with the carbon monoxide concentration of the blood and the rapidity with which the gas is absorbed. Practically no symptoms occur with a saturation of less than 30 per cent. At 40 per cent definite neuromuscular symptoms develop. At 50 per cent or higher the symptoms become aggravated and convulsions, delirium, paralysis and coma may supervene. Death almost invariably ensues when the concentration reaches 80 per cent.

The manifestations of carbon monoxide anoxemia may be divided clinically into three forms: (1) the acute form with sudden onset of symptoms resulting from overwhelming doses of the gas, (2) the acute form with delayed symptoms or sequelae in which the individual apparently recovers from acute asphyxiation but several days later suddenly develops severe nervous symptoms, (3) the chronic form, which will be discussed in this paper.

In the acute form the symptoms may develop instantaneously and, without warning, the victim may lose consciousness and die if not promptly removed from exposure to the asphyxiating gas. If carbon monoxide is inhaled in greater atmospheric dilution but in sufficient amount to cause a blood saturation of from 40 to 50 per cent, a characteristic train of symptoms develops. Among the outspoken symptoms may be mentioned frontal headaches, dizziness, yawning, blurring of vision, mydriasis, muscular weakness, tremulousness, ataxia, anorexia, nausea, bradycardia, hypertension, hyperpnea, palpitation and cutaneous flushing. With continued exposure these symptoms are followed by stupor, syncope, mental confusion, delirium, increased pulse rate, lowered blood pressure, slight elevation of temperature and glycosuria.

Patients generally recover from acute asphyxiation without any after-effects if promptly removed from the source of carbon monoxide. However, there are exceptions when several days after an apparently complete recovery severe secondary symptoms suddenly develop, chiefly referable to the central nervous system. These forms constitute the delayed type and are frequently fatal. The lesions found at autopsies are often widespread and may involve any portion of the central nervous system. As a result, symptoms or combinations of symptoms are produced which simulate many organic nervous diseases. These may be in the nature of cerebral hemorrhage, encephalitis, multiple sclerosis, spastic paraplegia, chorea and tetany. Other nervous symptoms that may be encountered are ocular palsy, optic neuritis, anesthesia, hyperesthesia and paresthesia. The mental symptoms include amnesia, aphasia, emotional instability, confusion, transient mania, dementia and feebleness.

CHRONIC CARBON MONOXIDE ANOXEMIA

Individuals repeatedly subjected to moderate or minimal toxic amounts of the gas causing comparative slow asphyxiation develop symptoms similar to those occurring in the milder forms of acute asphyxiation. It is in cases of prolonged and moderately severe carbon monoxide anoxemia that symptoms due to structural organic changes manifest themselves not unlike those occurring in the delayed type of acute onset.

In the ensuing description of chronic carbon monoxide anoxemia the symptomatology is largely based on the study and analysis of this series of ninety-seven cases which have been under my personal observation.

Forty-nine of this group were residents of West Virginia and thirty-seven of Maryland. The remaining ones were distributed through Pennsylvania, Ohio, New Jersey, Kentucky and Oklahoma. Sixty-seven were males and thirty females. The source of carbon monoxide was from natural gas (forty-three), illuminating gas (twenty-eight), gasoline engines chiefly automobiles (twenty-four), blast furnace and coke oven (each one). The duration of intermittent exposure ranged from several months to eighteen years. The

chief complaints were headache, vertigo, nervousness, neuromuscular pains, digestive disturbances, dyspnea and palpitation. The most outstanding symptom was headache, which occurred in fifty-eight of the cases. This was usually dull in character and located in the frontal region. At times it was throbbing in character. Frequently the patients complained of a sense of pressure in the frontal area. Headache was associated with vertigo in forty-six instances, a symptom often distressing to the patient and occasionally incapacitating to those engaged in manual labor, on account of the disturbance of gait with which it was frequently associated. Thirty complained of weakness and tremulousness in the legs, with ataxia. Several had complete loss of the use of the legs. Next to headache in frequency was the symptom of weakness which was mentioned in the history of fifty-two patients. This was usually general. However, many of the patients emphasized particularly weakness in the lower extremities. Practically all the patients in the series exhibited functional nervous and mental symptoms. Many were confirmed neurotics. Some were definitely psychotic.

NERVOUS AND MENTAL MANIFESTATIONS

Among the leading nervous and mental manifestations were feelings of depression, restlessness, anxiety and fears. Introspection, emotional upheavals, mental retardation with memory defects and at times confusion, besides headache, vertigo, weakness and ataxia already mentioned were prominent symptoms. Drowsiness and insomnia occurred frequently and in about equal proportion, paresthesia, chiefly in the extremities, occurred in thirty-six, speech defects in seven and paraplegia in three cases. Vasomotor instability was a fairly constant symptom, manifesting itself in morbid-flushing, local sweating, cold extremities and purplish congestion of the hands and feet. The special senses also were involved. Tinnitus aurium was an occasional complaint. Visual disturbances were noted in five cases. Sense of smell was perverted in some and diminished or completely abolished in others, and a certain number of patients complained of a bitter or copperish taste. The nervous and mental sequelae in carbon monoxide asphyxiation have been ably discussed in a recent article by Shillito, Drinker and Shaughnessy.³

NEUROMUSCULAR MANIFESTATIONS

Among the leading diagnostic symptoms relating to anoxemia from any cause are those referable to the neuromuscular mechanism. The outstanding symptom was pain, either dull aching in character or acutely spasmodic. The former appeared as general muscular pains or localized in the back, shoulders, epigastrium, lower part of the abdomen and the chest. Spasmodic pains occurred in the nature of cardiospasm, six cases, pylorospasm, one, enterospasm, three, anal spasm, three, and ureteral spasm, two. Dysuria, which was a symptom in ten cases, was probably due to spasm of the vesical sphincter.

In seventeen cases muscle spasm, usually confined to the legs, was observed, and in fourteen cases painful spasmodic contraction occurred in one or more of the toes. Fibrillating bundles of muscles were mentioned by twenty-six patients. Cramping of the toes and muscular twitching are regarded highly diagnostic of carbon monoxide anoxemia.

GASTRO-INTESTINAL MANIFESTATIONS

In the gastro-intestinal domain glossitis occurred in a few instances, and dysphagia, apparently due to cardiospasm, in several cases. The majority suffered with digestive disturbances. Gastric analysis was made in fifty-nine patients. Five showed achlorhydria and nineteen subacidity. In only seven instances was the acidity found to be above normal. Anorexia was a frequent complaint and sixteen patients mentioned nausea and vomiting as symptoms. Constipation of the spastic type occurred in forty-five and diarrhea in five. Two patients with symptoms of gastric ulcer for which they were receiving treatment were spontaneously relieved within three or four days after admission to the clinic. The prompt relief was attributed to their removal from daily exposure to escaping carbon monoxide from defective gas heaters. Thorough examinations failed to reveal any evidence of gastric ulcer in either case.

CARDIORESPIRATORY MANIFESTATIONS

Dyspnea and palpitation were the most common cardiorespiratory symptoms. Thirty-six patients complained of the former and twenty-seven of the latter. Coughing occurred in fifteen. Yawning, which is one of the most constant symptoms in the acute form, was mentioned in only five. Hoarseness was occasionally present. Precordial distress of varying degrees manifested itself in fourteen cases. Two of these patients suffered from typical angina pectoris and one developed symptoms of heart block.

Clinically there was a definite tendency toward slowing of the pulse and lowering of the blood pressure in contradistinction to increase in the pulse rate and elevation of the blood pressure in acute asphyxiation. Bradycardia occurred in approximately 30 per cent and hypotension in 50 per cent of the cases. Although all the patients were adults with an average age of approximately 40 years, in forty-eight the systolic pressure was 120 mm of mercury or less, and in twenty-five it was less than 110, with a diastolic pressure ranging from 60 to zero. There were only a few cases of hypertension. These were associated with arteriosclerosis and cardiorenal disease.

The basal metabolic rate, which was determined in thirty patients, was found to be significantly low, as should be expected. Excluding a case of toxic goiter with a rate of plus 49 per cent, the highest rate was plus 7.7 per cent. Twenty-four were either zero or below. Sixteen of these ranged from minus 11 to minus 40 per cent.

Definite changes were found in the blood. Hemoglobin estimation ranged from 100 to 110 in sixteen patients and the red cell count exceeded 5,000,000 in forty-four patients. In one instance it reached 7,800,000. There were no noteworthy changes found in the number or morphology of the white cells.

GENITO-URINARY MANIFESTATIONS

Vesical irritability with a tendency to nocturia, dysuria and pollakiuria was quite common. Several patients had incontinence. Glycosuria occurred in thirteen instances and albuminuria in twelve. Cylindruria was limited almost entirely to those who were suffering from a superimposed chronic nephritis.

In female patients menstrual disturbances in the nature of dysmenorrhea, menorrhagia and amenorrhea were noted. In male patients diminution of libido and potentia was an occasional complaint.

³ Shillito, F. H., Drinker, C. K. and Shaughnessy, T. J. The Problem of Nervous and Mental Sequelae in Carbon Monoxide Poisoning, *J. A. M. A.* 106: 669-674 (Feb. 29) 1936.

The effect of carbon monoxide asphyxiation on the reproductive organs of rats has been demonstrated experimentally by Williams and Smith.⁴ By exposing the animals daily to carbon monoxide for variable periods ranging from two weeks to 264 days, they produced sterility in both male and female rats, and testicular atrophy in the male rats.

PATHOLOGY

As carbon monoxide is nontoxic, there is no direct effect from inhalation of the gas. The hemoglobin molecule being converted from oxyhemoglobin to carboxyhemoglobin results in anoxemia and asphyxiation. This in turn may lead to structural changes in tissues, especially those richly endowed with blood, which normally utilize much oxygen, notably the central nervous system and the heart muscles. Clinically and experimentally it has been demonstrated that if a state of anoxemia persists over a sufficiently long period degenerative lesions may develop, especially in the brain, with resultant paralysis or other nervous manifestations.

Recently some very thorough and extensive experimental investigations on the neuropathology and blood chemistry have been made by Yant, Chornyak, Schrenk, Patty and Sayers⁵ of the U. S. Public Health Service. Their report contains eighty-four illustrations showing the lesions produced in the central nervous system resulting from comparatively rapid as well as from comparatively slow carbon monoxide asphyxiation. The demonstrable nerve lesions and the blood chemistry proved to be quite similar in asphyxiation from atmospheric oxygen deficiency to those produced by carbon monoxide. They arrived at the following conclusions:

1 With comparatively rapid carbon monoxide asphyxia of dogs (twenty to thirty minutes), circulatory changes (characterized by dilatation, stasis, perivascular hemorrhage and edema) were noted.

2 The edema was diffuse and severe, both perineuronal and perivascular.

3 There was a marked difference in the susceptibility of the nerve cells to oxygen deprivation. Those of the cortex, corpus striatum, dorsal motor nucleus of the vagus, and the dorsal sensory areas of the medulla were the most susceptible. The nucleus ruber, nuclei of the oculomotor, trochlear, abducens and facial nerve, and the large polygonal cells in the reticular formation of the medulla were the least susceptible.

4 There were two general types of degenerative changes in the nerve cells: (a) Some became shrunken and stained diffusely, (b) others showed varying degrees of chromatolysis.

5 Even in comparatively rapid carbon monoxide asphyxia, there was a diffuse generative change throughout the entire brain.

6 In comparatively slow carbon monoxide asphyxia (eight and fifteen hour exposure), the neuropathology of dogs differed from the preceding only in degree.

7 The degenerative nerve cell changes especially in parts of the cortex and the corpus striatum, were a great deal more severe than in comparatively rapid asphyxia.

8 In many of the hemorrhagic areas, as well as in some of the extremely dilated vessels, the red blood cells had undergone disintegration. The perivascular areas especially in the meninges were infiltrated to a greater degree with leukocytes.

9 There was an increase in number as well as in size, and an occasional difference in shape of the neuroglia. Occasionally very large clear spaces were found throughout the medullary substance. These were not observed in the shorter exposure cases.

10 There was an extensive proliferation of both neuroglia and endothelium in the dogs killed from sixteen to 165 days after comparatively slow carbon monoxide asphyxia.

11 Large cystic areas were found in the medullary substance of the brain. There was a marked cellular reaction in these areas consisting of phagocytic neuroglial ("granule") cells, which were large and filled with fat.

12 The proliferation of the endothelium was found at the sites of hemorrhages, collapsed vessels, and in vessels that were extremely dilated and contained fragmented blood cells.

13 Some of the nerve cells were fragmented and invaded by neuronophagocytic cells. In general the nerve cells in the deepest layer of the cortex adjacent to the medullary substances showed the most severe damage. Many cells, especially in the upper layers of the cortex, and most of the cells throughout the brain stem had completely recovered.

14 There were focal areas of myelin degeneration throughout the entire nervous system, including the peripheral nerves.

Their blood studies always revealed a marked hyperglycemia and hyperuricemia, the nonprotein nitrogen and urea slightly increased, creatinine remained practically normal and the inorganic phosphates increased. There was an increase in the hydrogen ion concentration and a decrease in the carbon dioxide content of the blood. The blood counts showed a slight but insignificant tendency toward an increase in hemoglobin, red blood cells, white blood cells and polymorphonuclears.

Williams and Smith observed an increased fragility of the red cells, which occurred only in animals daily exposed over 200 successive days. The hemoglobin percentage became significantly increased and remained high throughout the course of the experiments and there was a corresponding increase in the red cells.

These observations correspond exactly with the clinicopathologic reports of the patients who died of asphyxiation. Thus MacCallum⁶ states that it is common to find at autopsy symmetrical areas of softening with minute hemorrhages in the corpora striata and lenticular nucleus in illuminating gas poisoning.

Hedren⁷ found at autopsy numerous small hemorrhages in the pia mater, especially of the cord, with a tendency to softening. There were small thrombi in the left optic thalamus, fatty degeneration of the small vessels throughout the cerebral nervous system, thickening of the pia mater of the brain and degeneration of the central and peripheral nerves.

McConnell and Spiller⁸ reported areas of softening in the lenticular nucleus and microscopic cerebral lesions in a patient who died forty days after apparently recovering from an acute attack. In most of the fatal cases death was attributed to these cerebral lesions. Many of the lesions are characteristic of the epidemic form of encephalitis and the clinical syndromes produced cannot be readily differentiated from those caused by carbon monoxide. Moreover, the symptomatology is as protean in character in carbon monoxide anoxemia as in encephalitis. Gray⁹ states that hemorrhagic encephalitis follows frequently, and Armour¹⁰ calls attention to the fact that carbon monoxide may cause encephalitis. Four patients in the series studied exhibited typical symptoms of the parkinsonian type of chronic encephalitis.

COMMENT

A knowledge of these underlying pathologic changes, the result of anoxemia, makes it possible to interpret properly the clinical manifestations exhibited by these

patients and correlate them with the lesions responsible for the symptoms. If the interpretations including the history, train of symptoms, clinical phenomena and laboratory observations in this series of cases are correct, a definite clinicopathologic entity due to slow carbon monoxide asphyxiation is established.

Practically all the symptoms presented can readily be explained on this basis and certain well defined syndromes referable to disturbed function of the cerebrospinal, neuromuscular and cardiovascular systems can also be readily accounted for but not easily differentiated from other closely allied syndromes resulting from other causes. Carbon monoxide anoxemia may unquestionably produce the parkinsonian syndrome so frequently accompanying other forms of encephalitis, as well as any of the many other encephalitic symptoms, since the pathology is essentially that of epidemic encephalitis. Likewise certain heart lesions may be simulated, notably angina pectoris, to which anoxemia of the heart muscle has been ascribed as an etiologic factor. One of the patients suffered with frequent attacks until the cause was ascertained, which was almost continuous exposure to carbon monoxide from defective gas heaters. As soon as he was removed from the danger, the attacks promptly ceased. The thoracic pain and precordial distress, a frequent complaint, is also most likely due to oxygen deprivation of the heart muscles. The scope of this paper does not permit of a detailed discussion of the various clinical types of the disease. These will be more fully described in another paper.

It is obvious that in these chronic forms any therapeutic measure fails to influence the course and progress of the malady so long as the cause is not removed. After the patients are freed from exposure the treatment becomes symptomatic and largely hygienic. The solution to the problem lies in the administration of proper preventive measures through well trained industrial and sanitary engineers under the direction of municipal and state boards of health. More emphasis should be placed on public health instruction with regard to the hazard, and statistics should be more available, like those obtained from traffic accidents, in order to ascertain its real significance from a public health standpoint.

SUMMARY

- 1 A series of carefully studied cases of slow carbon monoxide asphyxiation has been studied.
- 2 The symptoms exhibited have been correlated with the pathologic lesions produced in experimental animals and found at autopsy.
- 3 The results establish the fact that slow carbon monoxide asphyxiation (anoxemia) produces a definite clinicopathologic entity despite views held to the contrary.
- 4 The symptoms arise predominantly from organs rich in blood supply, thus demanding much oxygen, such as the central nervous system and the heart muscles.
- 5 Owing to doubt and uncertainty as to the actual existence of the malady and a scant literature on the subject, the condition is not generally recognized by the profession and its importance has been underestimated.
- 6 Since there is no medicinal remedy when the organic changes have once developed, treatment must be directed toward its prevention by proper public health measures.

St. Paul and Twenty Third streets

THE HYPOGLYCEMIC STATE IN THE TREATMENT OF SCHIZOPHRENIA

BERNARD GLUECK, MD

OSSINING, N. Y.

During a recent trip to Europe I saw at first hand the application of a deliberately induced hypoglycemic state and insulin shock in the treatment of schizophrenia.

Through the courtesy of Dr Manfred Sakel¹ of Vienna, who introduced this method of treatment, his co-worker, Dr Karl T. Dussik, and Dr M. Muller and the staff of the Cantonal Hospital at Münsingen, Bern, I assisted in the application of this treatment for three weeks. This experience led to certain convictions based on actual observation of twenty psychotic patients undergoing insulin therapy, the personal examination of many patients who had been discharged as recovered, and the careful reading of the case records at Münsingen on which some of the statistics here quoted are based.

I am fully aware of the difficulties inherent in any attempt to estimate the worth and validity of statistical data concerning therapeutic results in psychiatry. Nevertheless, the statistics of the results of this therapy possess certain qualities which should gain for them serious attention. Time alone will tell how permanent the alleged cures are, one patient had remained entirely well for two years after the termination of the treatment, and there were several whose recovery has lasted about a year. Apart from the question of the permanence of the alleged cures, there is another important question, namely, how many of these restored patients might have made a spontaneous recovery, as sometimes happens even in severe cases of schizophrenia. These considerations apart, the available statistics are impressive, especially those based on the Swiss clinical material, which now embraces 118 cases of schizophrenia treated in ten private and public mental hospitals in Switzerland.

This new form of therapy was introduced by Sakel at Professor Potzl's clinic in Vienna in October 1933. Since then it has been employed in private and public mental hospitals in Switzerland, in the Netherlands, in Poland and in isolated German clinics, has recently been introduced at the Moscow Psychiatric Clinic by Kronfeld, and has been investigated by a special committee of the Board of Control of Great Britain, whose report will be published shortly.

RESULTS OF TREATMENT

The first available statistics were published by Dussik and Sakel² and comprise 104 cases, consisting of fifty-eight recent ones (duration under one-half year) and forty-six older ones. In the group of fifty-eight recent cases a good recovery was made in 88 per cent, enabling these patients to resume former occupations in the community, while in 70.7 per cent a complete recovery was attained. In the group of forty-six older cases (duration of illness more than one-half year) a good social recovery was made in 47.8 per cent, whereas a complete remission was attained in 19.6 per cent of the cases.

The investigators did not have complete freedom in their selection of the patients for treatment, owing to

¹ Sakel, Manfred. Neue Behandlung der Schizophrenie. Vienna, M. Perles, 1935.

² Dussik, K. T. and Sakel, Manfred. Ergebnisse der Hypoglykämie-schockbehandlung der Schizophrenie. Ztschr. f. d. ges. Neurol. u. Psychiat. 155: 34, 1936.

limited personnel at the Vienna clinic and because of other local reasons. New cases were taken on as the old ones were discharged, but naturally, whenever possible, they gave preference to the recent cases. Of the good remissions, fifteen patients have been well now (Jan. 10, 1935) about a year, and thirty-four for more than half a year. Of the group of recent cases there were nine relapses, as follows: three patients who had been considered completely restored, five who had made a good recovery and one who had made a social recovery. Of these nine patients, five were again placed under treatment, of whom three had a good recovery, one showed no benefit and one is still under treatment. All other cases which were considered to be of recent origin at the time the treatment was instituted show to the present an unchanged state of well being. Of the older cases, six showed a recurrence. All six of these patients were placed under treatment again with the following results: One gained a complete recovery, one gained a good recovery, two gave questionable results, one showed no improvement whatever, and one was still under treatment at the time of their report.

The writers consider in detail the effect of the new therapy on the various forms of schizophrenia. In common with the experience of others who have employed this therapy, they found that the paranoid types respond more favorably to the treatment than the other types. Another remarkable fact is the duration of the treatment. A computation of the length of treatment of the first twenty patients on the list of those who fully recovered gives an average duration of treatment of fifty-two and a fraction days. In view of the customary responsiveness of schizophrenic patients to the various forms of treatment hitherto employed, this is remarkable. I might also add that the quality of the recovery in most of the ex-patients whom I examined was of an exceptionally satisfactory nature, of a kind only rarely seen in those schizophrenic patients who achieve a spontaneous remission. These impressive Vienna statistics are fully corroborated by the as yet unpublished statistics of the Swiss material. I am indebted to Dr. M. Muller of Munsingen for the availability of this material for the present purpose.

In an address delivered before the Medical Society of Bern-Stadt Feb. 13, 1936, Müller³ reviewed the entire subject and reported seventy-five cases in which treatment had been completed at seven Swiss hospitals.

In estimating the results in these cases, he calls attention particularly to the two categories of complete recovery and total failure. He rightly states: "The concept 'improvement' is such a vague and tenuous one that it had better be entirely left out in any critical examination especially in this obscure field of schizophrenia, and when the estimate is made by various investigators. On the other hand, the concept 'complete recovery' can mean only one thing, the total rehabilitation of the personality, including affectivity, and also, naturally, complete capacity for work."

He divided his material into those in whom treatment was initiated within one-half year after the onset of the illness, those who had been ill one and a half years and those who had been ill more than one and a half years.

Of the entire group of seventy-five patients thirty-six, or 48 per cent of the total, achieved complete recovery. Of the thirty-six who recovered, twenty-six had been ill less than one-half year, nine between one-half and one and a half years, and one more than one

and a half years. The twenty-six recent cases in which recovery occurred constituted 76 per cent of the total of thirty-four cases in which illness had lasted less than one-half year. There were fifty-one patients in all of those who had been ill one and a half years or less. Of this total group thirty-five, or 68 per cent, made a complete recovery. Total failure occurred in eighteen of the entire seventy-five cases, but only in eight, or 15.6 per cent, of the fifty-one patients who were ill one and a half years or less. In the remaining twenty-one cases of the total of seventy-five, improvement was noted.

I agree with Muller when he says that these figures are in such marked contrast to any hitherto published figures on spontaneous recoveries that there can be no doubt about the superior worth of this method of treatment.

Since these statistics were computed, Muller and his collaborators in ten other Swiss mental hospitals, both private and public, have had at their disposal forty-three additional records of cases of schizophrenia in which the treatment has been completed, so that statistics are now available on a total of 118 Swiss cases.

Of this total, fifty-two of the patients had been ill less than one-half year, and forty of these, or 78.8 per cent, made complete recoveries, as compared with 76 per cent of similar material reported on last February. Seventy-eight of the total of 118 patients had been ill one and a half years or less, and fifty-four of these, or 68.2 per cent, made full recoveries, as compared with 68 per cent in the earlier similar material. There were forty patients of the total of 118 who had been ill more than one and a half years. Of these, two made full recoveries, sixteen were improved and twenty-two remained uninfluenced, whereas of the seventy-eight patients who had been ill one and a half years or less only eleven remained uninfluenced by the therapy, and, in addition to the fifty-four who made full recoveries, thirteen also showed improvement.

The high degree of agreement between the earlier and the present enhanced material must be looked on as an important element in estimating the validity of these statistical observations.

COMMENT

Should the results reflected in these statistics prove to be entirely permanent, or even considerably so, the discovery of this method of therapy of the psychoses will constitute, because of its far-reaching biologic, medical and social implications, one of the greatest achievements of medicine. Moreover, it opens unlimited research possibilities in directions other than schizophrenia. The evidence is far from conclusive that the effects of the hypoglycemic state and of the insulin shock in patients with schizophrenia is something specific to this form of disorder. Indeed, encouraging results have been reported in a few cases of menopausal depression and in a few cases of severe compulsive states. Such theoretical considerations as Sakel has permitted himself to advance have been stated in the two publications already referred to and in a forthcoming publication by the same author of an address given March 19, 1936, before the Psychologic and Neurologic Clinic at Vienna.⁴ The phenomena of the hypoglycemic state, especially in those patients who react with profound shock, are extremely varied, and, when viewed from the standpoint of a genetic-dynamic psychology, reveal an amazing array of manifestations which can best be understood through an acquaintance

³ Muller, Schw. z. med. Wchnschr., to be published.

⁴ Sakel, Manfred, Wien. med. Wchnschr., to be published.

with the phenomena of regression, regression, projection catharsis, transference and other well known psychoanalytic concepts. Plus is the more amazingly interesting because the therapeutic agent, whatever its specific mode of influence may be is of a biochemical nature. Certainly, the average patient's reaction to this sudden deprivation of the organism of its sugar content has much in it of the nature of a profound organismal and personality disintegration, albeit temporary in duration, as does the reaction to the reintroduction of the required quantity of sugar reflect in many ways, perceptible stages of a reintegration on neurologic and psychic levels. Tempting as is the desire to carry this thought further, this is not the place for it.

A few words as to the alleged dangers of this form of therapy. The serious and far-reaching manifestations of accidental insulin shock are well known. It is conceivable, therefore, that the deliberate introduction of a profound state of hypoglycemia with the necessity of exploiting its effects to the furthest possible limits short of endangering the patient's life, as is required by this form of therapy, carries with it a considerable element of danger. No other form of psychiatric therapy requires as much care skill and caution in its application as does this. It demands also a type of nursing personnel and hospital organization second to none in efficiency, team work and readiness for emergency intervention. Four deaths have been recorded in connection with the treatment, three in Vienna and one in Switzerland, but it is impossible to state with accuracy what percentage this constitutes of the total treated. The first mortality occurred during the early days of the use of this therapy, when the technic was not so well perfected as it is today. The second was due to coronary disease, which was not detected during the preliminary physical examination. The third death was due to a necrosis of the pancreas. The death in Switzerland occurred about three hours after the termination of the hypoglycemic state from an acute pulmonary edema in a patient over 50 years of age.

It should be stressed, however, in this connection, that because of the almost instantaneous restorative effects which the introduction of sugar brings about, the dangers of the hypoglycemic state are not as great as are the dangers connected with some of the forms of narcotic therapy in the psychoses, or those encountered at times in connection with the malaria therapy of dementia paralytica. As to the possible injurious physical sequelae of repeated insulin shock, nothing definite can be stated as yet. Certainly, while undergoing the treatment, the patients appear to be in fine physical condition, usually gain weight, and, aside from a slight sense of fatigue, do not complain of physical discomfort during the time when they are not in the hypoglycemic state.

As to the technic of application of this form of treatment, the reader is referred for a detailed description to the publications already cited. The object is to achieve a progressive insulimination of the patient through the intramuscular administration of daily increasing doses of insulin until the so-called shock dose is attained. Apart from the experience required to recognize the signs indicative of the attainment of the shock dose and the skill in dealing with such emergencies as might occur, this phase of the technic is not as difficult as is the phase that has to do with the interruption of the hypoglycemic state. The great difficulty lies in the total unpredictability of the patients' reactions from day to day or even from hour to hour.

Even the same patient reacts differently from day to day, and experience alone is the guide as to when and how to intervene. In his latest paper, already referred to, Sakel goes into great detail in explaining the differences of procedure indicated in the different forms of schizophrenia and in the changing clinical phases that occur in the course of the treatment. But while the theoretical basis for these indications may be valid, the experiences encountered in the actual application of the treatment do not permit of a close adherence to these prescriptions. The therapy, apart from certain general guiding lines, is an exceedingly individual therapy, in which not only general medicinal factors play an important role but keen psychiatric and psychologic insight are also required for the correct exploitation of the curative possibilities furnished by the hypoglycemic state in the individual case and for the avoidance of serious errors of misinterpretation and misapplication. Finally, a word of caution. Do not confuse this form of therapy with previous attempts in the use of insulin in the psychoses.

TREATMENT OF DEMENTIA PARALYTICA

COMPARATIVE STUDY OF COMBINED ARTIFICIAL HYPERPYREXIA AND TRYPARSAMIDE VERSUS THERAPEUTIC MALARIA. A PRELIMINARY REPORT

CLARKE H. BARNACLE, MD
FRANKLIN G. EBAUGH, MD
AND
JACK R. EWALT, MD
DENVER

This communication is a preliminary report of a long term study of the comparative value of combined artificial fever and tryparsamide versus therapeutic malaria in the treatment of dementia paralytica. Tryparsamide and heavy metal chemotherapy were administered in the follow-up care of the sixty patients observed in both series.

From the time of Wagner von Jauregg's original report in 1917 on the therapeutic value of malarial fever in the treatment of dementia paralytica there have been many confirmatory publications from European and American medical centers. There is no doubt that malaria is distinctly beneficial in combating this disease, but many workers are of the opinion that the procedure leaves much to be desired. In 1929 Neymann and Osborne¹ and later, in March 1930, King and Cocke² reported successful treatment of dementia paralytica with pyretotherapy produced by diathermy and stated that their results compared favorably with those obtained from malarial inoculation. In a comparatively recent monograph Hinsie and Blalock,³ pioneer investigators with the ultra-high frequency oscillator, reviewed the literature of pyretotherapy in the treatment of dementia paralytica and reported on comparable groups of patients treated by

various methods the high frequency current followed by tryparsamide, the high frequency current alone, malaria, and tryparsamide. They indicated that their best clinical results were obtained with the high frequency current followed by tryparsamide. These workers have initiated a recent treatment series of dementia paralytica in which electropyræxia and tryparsamide are administered simultaneously. Simpson and his co-workers⁴ combined chemotherapy (bismarsen, iodobismutol or tryparsamide) with the radiotherm treatment of neurosyphilis. In December 1935 Simpson⁵ reported unusually good results in the treatment of dementia paralytica utilizing the Kettering

hypertherm. His method was a combination of fifty hours of hyperpyrexia (105-106 F) and thirty injections of a chemotherapeutic agent, bismarsen was given prior to each heating.

The experience of the Colorado Psychopathic Hospital staff is in agreement with Wagner von Jauregg,⁶ Solomon and Epstein⁷ and others. Strecker and Ebaugh⁸ in their textbook say "In our series permanent results are much more numerous in the group which has had the advantages of intensive postmalarial chemotherapy, so that we have come to regard this as an essential part of the treatment of general paresis—tryparsamide has been found to be particularly effective. To achieve clinical arrest, prolonged treatment is essential, in no case should the duration of treatment be less than two to three years." Our results with malarial therapy⁹ are comparable to other published reports but we felt that other methods were worthy of investigation. In February 1935 we initiated a long term study of the value of combined artificial fever and tryparsamide therapy as compared to therapeutic malaria followed by tryparsamide.

MATERIAL AND METHODOLOGY

The University of Colorado Medical School and Hospitals was lent three Kettering hypertherms¹⁰ by the General Motors Company for experimental research particularly in the field of neurosyphilis. Three machines were installed in the early part of February 1935, and immediately thereafter this comparative study of therapeutics in dementia paralytica was inaugurated. From this date to February 1936, a one year period, sixty patients with dementia paralytica were treated by one of two methods, thirty patients received a com-

bined course of artificial fever and tryparsamide, while the other thirty were given a course of malaria. Both groups were followed up in treatment by weekly injections of tryparsamide, and if a period of six months elapsed after pyretotherapy, bismuth subsalicylate was administered at weekly intervals.

All the patients treated were suffering from the adult form of dementia paralytica. It will be noted in table 1 that fifty-one of the sixty patients were below 50 years of age, while nine were above that age. The youngest patient was 20 years of age and the oldest 61. The average age of the fever group was 37.9 years, as compared to 42.6 years in the malaria series. Of the total number of patients reported, there were forty-four males and sixteen females. The average age of all males was 41.4 in comparison with 37.1 years of the females.

The average duration of symptoms of dementia paralytica for the total series of sixty patients prior to treatment was 18.45 months. In the hyperpyrexia group the duration was 16.7 months, while in the malaria series it was 20.2 months.

Fifty patients had received no antisyphilitic therapy during the year prior to treatment, while ten patients had been given various kinds of chemotherapy without improvement, six of these were in the fever group and four in the malaria division. In the former series two patients had previously received malaria without benefit, while in the latter group only one patient had had a course of malaria prior to this study.

We have classified our cases of dementia paralytica for convenience into three main groups as follows:

Group A. The deteriorated group, in which destruction of the central nervous system had proceeded to an advanced degree, with little possibility of retarding the disease process. These patients presented definite evidence of mental deterioration on examination.

Group B. An organic reaction with psychosis of functional coloring. Clinically this group included psychoses similar to the functional disturbances seen

TABLE 2—Hours of Artificial Fever and Number of Treatments

| Number of Hours | Number of Patients | Number of Treatments | Number of Patients |
|------------------------------|--------------------|-----------------------------------|--------------------|
| 60-60 | 1 | 14 | 1 |
| 50 | 12 | 13 | 1 |
| 40-50 | 12 | 12 | 1 |
| 30-40 | 4 | 11 | 2 |
| 20-30 | 1 | 10 | 23 |

| | | 8 | 1 |
| | | 7 | 1 |
| Average number of hours 44.5 | | Average number of treatments 10.4 | |

in manic excitements, with depressions and other reaction types in addition to the organic symptoms present in dementia paralytica.

Group C. Cases without signs of deterioration of dementia paralytica in which mental symptoms were frequently transitory and exhibited before any signs of deterioration occurred. This group included delirious reactions and neurologic irritative phenomena, as seen in convulsive seizures, aphasic attacks, and combinations of meningovascular upsets.

Of the sixty patients of the total series there were seventeen in group A, thirty-three in group B and ten in group C. In the malaria classification there were eight in group A, eighteen in group B and four in group C, in the fever series there were nine in group A, fifteen in group B and six in group C. While this was a fairly even distribution of patients, no attempt was

10. The Kettering hypertherm was conceived and perfected at the Miami Valley Hospital, Dayton, Ohio, and at the Research Laboratories of the Frigidaire Division of the General Motors Corporation, Dayton, Ohio. We are indebted to Dr. Walter M. Simpson and Mr. Charles F. Kettering of the General Motors Company for the privilege of using three hypertherms at this clinic.

made at selection. The patients were assigned to the two services alternately when the question of treatment arose. The same prerequisites were demanded of each group, the usual contraindications were considered. In this period of one year ten additional patients with dementia paralytica were disqualified for either pyretotherapy or malaria because of gross contraindications.

APPARATUS AND TECHNIC

In the production of artificial fever we are using the Kettering hypertherm¹¹. This apparatus is an air conditioned cabinet through which moist heated air is circulated by electrical blowers. Fever induction by this method depends on two factors: (1) the transfer of heat by conduction from the circulating hot moist air and (2) the prevention of the normal loss of heat from the body by radiation and evaporation. The control of these factors accounts for the elevation of body temperature and its maintenance at a desired level.

The prescribed course of hyperpyrexia in the treatment of dementia paralytica is fifty hours of from 105 to 106 F given in ten sessions of five hours each. The interval between treatments in the series of thirty cases was from four to seven days. It is our feeling that shorter intervals tend to debilitate the patient and

TABLE 3—Elevations and Chills in the Malaria Series

| Number of Elevations | Number of Patients | Number of Chills | Number of Patients |
|----------------------------------|--------------------|------------------------------|--------------------|
| 16 | 1 | 14 | 1 |
| 15 | 1 | 13 | 2 |
| 14 | 5 | 12 | 3 |

| 5 | 2 | 3 | 1 |
| | | 2 | 1 |
| Average number of elevations 9.9 | | Average number of chills 8.2 | |

increase the hazards of pyretotherapy. With this cautious schedule the great majority of our patients gained or held their original weight during the course of treatment.

In the thirty patients treated with the Kettering hypertherm, the average number of hours of 105-106 F fever was 44.5. The average number of treatments in this group was 10.4. It will be seen in table 2 that the majority of the patients received the prescribed course.

Tryparsamide, 2 Gm, was administered intravenously at the height of each session, usually during the first or second hour of elevated temperature. Following the course of hyperpyrexia the patient received tryparsamide, 3 Gm, at weekly intervals.

In the group treated with malaria, we used the tertian strain of plasmodium. From 1 to 2 cc of citrated malaria blood was injected either intravenously or into the muscle. It will be noted in table 3 that the average number of elevations of temperature was 9.9 while the average number of chills was 8.2. It is our practice to follow each course with biweekly injections of neoarsphenamine for six doses before tryparsamide chemotherapy.

RESULTS

The results of the comparative study of the two series treated between February 1935 and February 1936 were analyzed in April 1936. It is obvious that

some cases will have been observed over a longer period than others. As we have mentioned before, this communication is a preliminary report of a proposed long term study and we do not intend to draw any conclusions at this time, realizing that a one year study is an extremely short period of observation.

Our clinical results are summarized in table 4. In the combined artificial fever and tryparsamide group there were twelve complete arrests, or 40 per cent,

TABLE 4—Types of Treatment and Clinical Results

| Clinical Status | Combined Artificial Fever and Tryparsamide | | Therapeutic Results | |
|-----------------------|--|------------|---------------------|------------|
| | Number of Cases | Percentage | Number of Cases | Percentage |
| Complete arrest | 12 | 40.0 | 7 | 23.3 |
| Improved | 9 | 30.0 | 12 | 40.0 |
| Unimproved | 8 | 26.6 | 7 | 23.3 |
| Died during treatment | 0 | 0 | 1 | 3.3 |
| Died subsequently | 1 | 3.3 | 3 | 10.0 |
| Totals | 30 | 100.0 | 30 | 100.0 |

while in the malaria series there were seven complete arrests, or 23.3 per cent. One will note nine improved cases in the fever group (30 per cent) as compared to twelve improvements in the malaria series (40 per cent). This means that in the fever series 70 per cent of the patients were definitely benefited by their treatment while in the malaria group 63.3 per cent were likewise helped. Eight fever cases were unimproved (26.6 per cent), seven of the malaria series failed to show improvement (23.3 per cent). No patients died during the course of hyperpyrexia but one died two weeks after the completion of an artificial fever course from a cerebral hemorrhage. One patient died during a course of malaria and three have died subsequently.

It may be interesting to compare the results in the group A, B and C classification in table 5. The great majority of complete arrests occurred in group C, particularly in the fever series. The next best results were obtained in group B, dementia paralytica patients with psychoses in which there was a functional coloring. The majority of the failures were in group A, the deteriorated dementia paralytica patients.

We recognize that it is very difficult to ascertain the exact status of the clinical picture in dementia paralytica. The picture may be a changing one especially

TABLE 5—Group Classification in Relation to Clinical Results

| Clinical Status | Combined Artificial Fever and Tryparsamide | | | Therapeutic Malaria | | |
|-----------------|--|---------|---------|---------------------|---------|---------|
| | Group A | Group B | Group C | Group A | Group B | Group C |
| Complete arrest | 0 | 6 | 6 | 0 | 6 | 1 |
| Improved | 3 | 6 | 0 | 3 | 7 | 2 |

| Died | 1 | 0 | 0 | 2 | 2 | 0 |
| Totals | 10 | 14 | 6 | 8 | 18 | 4 |

in the groups we are observing, for in many instances the lapse of only a few months has occurred since the completion of the fever or malaria course.

In considering the apparently better results in the fever group over the malaria series, we must evaluate the age distribution and duration of symptoms prior to treatment (tables 1 and 6). In that the average fever patient was younger and his symptoms were of shorter duration, he was perhaps a better candidate for either type of treatment. One must consider, moreover, that the fever patients had the advantage of tryparsamide chemotherapy during the hyperpyrexia sessions.

¹¹ A detailed description of this apparatus is given by Simpson.⁵

The cerebrospinal fluid serologic results are presented in table 7. It will be noted that practically the same number of patients showed improvement in the two series. There were four serologic reversals in the fever group as compared with none in the malaria series, but we were unable to check eight cases in the latter group in contrast to three in the former. We have followed the serologic grading of Solomon and Epstein⁷ and likewise have not considered the serologic reaction of the blood as significant in determining the efficiency of

TABLE 6—Duration of Symptoms Prior to Treatment

treatment. Our results demonstrate no parallelism between clinical and serologic improvement, as one would expect in a one year study.¹² It is a known fact that as years go by following the treatment of dementia paralytica the cerebrospinal fluid tends to become negative.

COMMENT

In conducting the two types of treatments simultaneously we have been impressed with certain advantages and disadvantages in each type of treatment. In regard to the combined artificial fever and tryparsamide method its advantages are that tryparsamide may be administered without interfering with the course of treatment, prescribed dosage of treatment may be given, treatment may be terminated instantly if complications arise, secondary anemia does not contraindicate treat-

TABLE 7—Serologic Results of Cerebrospinal Fluid

ment, emaciation of the patient is no contraindication, we have observed no evidence of hepatic or splenic damage from this method, hospitalization is not necessary in many patients and some of them may work between the fever sessions and the induction of a disease is not necessary. The disadvantages of the mechanical fever method include the fact that uncooperative patients may require narcosis, treatment can be carried on only by specially trained personnel in hospitals, and the period of treatment is comparatively long (from five to ten weeks).

The advantages of malarial fever in the treatment of dementia paralytica include the facts that uncooperative patients do not require narcosis, treatment may be administered in private practice without specially trained personnel, and the course of treatment is relatively short (from two to three weeks). The disadvantages of induced malarial fever include the facts that tryparsamide cannot be given simultaneously with malaria, the amount of fever cannot always be controlled and many patients are immune to malaria, in some cases it is difficult to terminate malaria when complications arise, this method tends to produce a secondary anemia which may be difficult to combat, the majority of malaria patients lose weight, occasionally hepatic or splenic damage results from the disease, hospitalization is usually imperative, and the induction of a secondary disease is necessary.

SUMMARY

1. A comparative study was made of combined artificial fever and tryparsamide versus therapeutic malaria in the treatment of sixty cases of dementia paralytica over a one year period. Chemotherapy followed both methods.

2. During this period in the artificial fever series 70 per cent (twenty-one patients) were definitely benefited while in the malaria group 63.3 per cent (nineteen cases) were likewise helped.

3. The serologic reactions of the cerebrospinal fluid in both groups did not parallel the clinical results.

ABSTRACT OF DISCUSSION

DR. A. E. BENNETT, Omaha. The fact that remissions in dementia paralytica are obtainable by a large variety of fever inducing agents, malaria, sodoku, typhoid vaccine, pyrogenic bacteria, sulfur in oil and the various physical fever-producing methods makes it appear that the heat production regardless of the cause is a curative agent. If this fundamental fact is established by further studies, the safest and most economical method will be the general method of choice. I should like to ask whether the authors feel that more malarial fever might have increased their percentage of improvement. It is my impression that the best results from malarial fever are seen in patients who receive from fourteen to sixteen malarial fever elevations. I have seen improvement at times in apparently hopeless cases when twenty or more paroxysms were permitted. At the Douglas County Hospital and Lutheran Psychiatric Hospital in Omaha for the past ten years 182 patients with dementia paralytica received malarial fever therapy. About the same percentage of improvement has occurred as universally reported. The immediate mortality of malarial therapy in this group has been 6 plus per cent. I do not feel that the mortality of malarial therapy has been sufficiently emphasized in reported studies. In reviewing the literature one finds that the immediate mortality of malarial therapy is high. In large series of cases it runs about 10 to 20 per cent. This is a tremendous drawback to this form of therapy. There is also a delayed mortality rate that is hard to evaluate. There is practically no need for immediate mortality from Kettering hypertherm therapy. At the University of Nebraska in one and one-half years experience with the Kettering hypertherm we have completed treatments in eleven cases of dementia paralytica, six of which were simple dementing types and five expansive types. We have used the same technique as outlined in the Colorado study, namely, fifty hours of fever in ten sessions above 105 F. We have used bismuth arspenamine sulfonate instead of tryparsamide with each fever session. Nine of these eleven patients are in complete remission and at full occupational status. One of these patients was a complete malarial failure. One other patient now under treatment has been in a psychopathic hospital almost a year and received seventeen malarial paroxysms followed by tryparsamide therapy without improvement. He is practically normal now after about thirty-five hours of fever therapy.

¹² Ferraro, Armando, and Fong, T. C. Malaria Treatment in General Paresis. *J. Nerv. & Ment. Dis.* 65: 225 (March) 1927.

From observations with Kettering hypertherm therapy in dementia paralytica I can say that the immediate results are at least equal to malarial therapy without its hazards. It remains for further investigative studies to decide whether the results are superior, how much the total treatment course is shortened, and what changes occur in the serologic formula.

DR. PAUL A. O'LEARY, Rochester, Minnesota. I have passed through the era of enthusiasm for the mechanical units which produce fever for the treatment of neurosyphilis and still feel that malaria therapy is the superior method of the two. In patients with asymptomatic neurosyphilis, or preparetic neurosyphilis the incidence of relapse, both clinical and serologic, is decidedly lower following malaria therapy than it is after the electrical forms of fever therapy. Although fever is the common factor to both malaria and vapothermy it does not seem that fever alone is responsible for the good therapeutic results obtained. The reasons for this belief are as follows: The thermal death point of *Spirochaeta pallida* is approximately 111 F. The good results in the treatment of gonorrhea and gonorrheal arthritis by hyperpyrexia may be due to the fact that the thermal death point of the gonococcus is 103 or 104. Although we are unable to raise the patient's temperature to the thermal death point of *Spirochaeta pallida*, good therapeutic results are noted in patients treated for neurosyphilis in whom the temperature did not exceed 104 F. The second point against fever per se being the cause of improvement is the time factor. In those patients treated by the vapothermy clinical remissions may appear a bit sooner than following malaria therapy. However, relapses both clinical and serologic occur much sooner following vapothermy than malaria treatment. The results from malaria, although a trifle slower in appearing are apparently more permanent. If fever was producing the therapeutic results by a "cooking" process it is evident that the improvement would appear earlier than from eighteen to twenty four months following the fever course. The third point against the factor of fever alone as the therapeutic mechanism is that several years ago I treated with malaria therapy twelve patients with early syphilis whose spinal fluids became more positive while undergoing arsphenamine and bismuth therapy. Six of these patients returned within a period of six to ten months after the malaria therapy presenting those bizarre cutaneous signs of syphilis known as precocious tertiarism, in which signs of secondary and late syphilis are present in the same lesions. To me these lesions were evidence that *Spirochaeta pallida* had not been "cooked" by the malaria fever. Accordingly, it must continue to be acknowledged that the various methods of fever therapy are used empirically. The advantage of the mechanical units is the opportunity they afford to give as many treatments or as few as are needed, whenever they are desired. The disadvantage of the electrical units is the lower remission rate and higher incidence of relapse than is noted following malaria. I agree with the authors that the vapothermy method of treatment should be continued, with observation of a larger series of patients over a longer period of time.

DR. WALTER FREEMAN, Washington, D. C. In these days of superelectrical instruments, the malaria therapists are having a difficult time. I was glad to hear Dr. O'Leary come to the rescue of this time honored method of treatment. The trouble with all these reports, not excepting Simpson's, is that the results have not been followed for a sufficient period of time to exclude the possibility of relapses. If one considers only the first year cases the first two year cases, even the first three year cases, fully studied I think it will be found that the percentage of relapse rises with the passage of time. Malaria has already been evaluated on the basis of studies on patients followed over a period of ten years. One of the main difficulties with the Kettering hypertherm is the treatment of disturbed, deteriorated patients. It is the relatively healthy, cooperative patients in the early stages of the disease, who can be persuaded to get into the fireless cooker and stay there during the course of the treatment. I will admit that it is only during the first hour while the fever is rising, that the objections are vocal, but then the patients seem to subside into a state of semiconsciousness and, even without the administration of sedatives lie there in relative insensibility, if not in comfort. The precautions that were originally hedged around the malaria treatment, enforced hospitalization, special nursing and so on

made the malarial treatment rather difficult to give. However, with the passage of time and with the additional experience gained it has been found that most of these patients can be treated in the open wards of the general hospitals and even in the home. In Washington we have a series of some thirty or forty patients now who have been injected with malaria and have been sent home to report the occurrence of the first chill and then have been treated at home, either in whole or in part. These patients, of course, have been of the relatively fresh type not deteriorated and they have done exceptionally well. Some of them have been followed over a course of five years now. While I am not ready to report the results until the series is enlarged I can say that the results have been quite gratifying. No doubt there is a place for the Kettering hypertherm. Patients who are poor risks for malaria can undoubtedly be treated more safely by this method. However, it is going to take a longer time before the results can be satisfactorily evaluated.

DR. WILLIAM NELSON, St. Louis. There are certain things I think physicians need to have some caution about in connection with either one of the treatments. In the first place, I rather doubt seriously that patients can be intelligently classified into groups 1, 2 and 3 or A, B and C symptomatically. As a matter of fact, it is very difficult. It has been difficult to determine just to what extent deterioration has taken place in an individual and to what extent toxicity is a factor in the symptoms that are present. I have seen some people show some rather aggravated symptoms clinically. I have assumed at times that they were indications of structural deterioration. As a matter of fact, I have seen functional integrity restored, to a degree, in some of those cases that I thought were rather hopelessly deteriorated. So I think that, from a symptomatic standpoint, it is rather difficult to classify the patients in that way and consider results then, in terms of classification. There are certain things for and against malaria and hyperthermia as has been stated. I think not the least of them, of course, in favor of hyperthermic treatment, is the difficulty of inoculation of some patients with malaria. I don't know the disparity between the inoculability of patients suffering from syphilis and those of the general population. I know that in my series of 107 cases we have had extreme difficulty in inoculating some of the patients. In some of the patients after repeated attempts, we have tried to treat them with other means, including hyperthermic treatment, and got no results. Whether we have gotten satisfying benefit from the malaria or not, in my opinion, is a question. I don't think that it can be concluded arbitrarily that any one method of treatment is better than another. I am glad to see this comparison made. I am like Dr. Freeman in thinking that we need to defer our conclusions until we have had sufficient experience with it to know what degree of return of disease we have, the length and period afterward, and just what the ultimate results are.

DR. HANS H. F. REESE, Madison, Wis. Dr. Bennett quoted figures of unusual high mortalities as the result of malarial therapy. Do his statements represent the immediate mortality during the course of fever paroxysms or do they incorporate late fatalities also of follow-up cases? I recommend to a therapist who encounters over 20 per cent of fatalities with a method of treatment for dementia paralytica to give up his endeavors with malarial fever, as he is not qualified to supervise a therapy which in the hands of experienced investigators has less than 5 per cent of mortalities. During the last years my associates and I have not lost a single case of neurosyphilis not because of selecting ideal cases but because of accurate clinical supervision. Artificial hyperpyrexia is not superior to therapeutic malaria. I prefer the latter to the former.

DR. CLARKE H. BARNACLE, Denver. In answer to Dr. Bennett's question it might be said that we give an average of eight to twelve malaria elevations and believe this amount to be sufficient. In this series we averaged 9.9 elevations. This is the policy that has been followed for at least ten years at the Colorado Psychopathic Hospital. I appreciate the discussion of Dr. O'Leary and Dr. Freeman. I will say that we are open minded. We want to know ourselves which is the better method, if there is a better method but it will take a long time to determine. We plan at least a five year study,

most likely a ten year study of the question. In regard to the management of disturbed cases, three of the thirty hyperpyrexia patients required narcosis throughout the heatings. Our classification is just one of convenience, so we can talk the same language. When I talk about group A, I mean the deteriorated type, and I think that it is something that can be used to advantage.

VASCULAR COLLAPSE IN TOXEMIA OF PREGNANCY

FRED L. ADAIR, MD

CHICAGO

ARTHUR B. HUNT, MD

ROCHESTER, MINN.

AND

RUPERT E. ARNELL, MD

CHICAGO

A thorough study extending over a period of years has recently established the risks of repeated pregnancies for the patient suffering from an increasingly severe toxemia of the nonconvulsive, vascular renal type. Real hazards are to be anticipated whether the etiology of the renal damage is from a glomerulonephritis or prolonged essential hypertension acquired independently of pregnancy or from an insidious and progressive nephritis or hypertensive disease in successive pregnancies. These risks consist not only of abortions or fetal deaths but also of a definite shortening of life expectancy and a loss of maternal life in the immediate puerperium.

Experience with the type of toxemic patient who is in jeopardy from shock shortly after delivery has prompted this study.

The careful work of Simons and Rasmussen,¹ following the blood pressure through pregnancy, labor and the puerperium in the same patients, showed a gradual rise of systolic, diastolic and pulse pressure during gestation. They observed a sudden rise during labor with a marked decrease immediately after delivery, and then a gradual decrease to normal at about six weeks post partum. They noticed that in toxemic patients the drop in blood pressure immediately after delivery was more pronounced and was followed by a secondary rise and more gradual secondary drop to lower values. In these toxemic patients an exaggeration of the normal reaction of blood pressure to gestation and parturition is often seen.

Bailey² in 1911 first called attention to shock occurring soon after delivery in eclampsia and preeclampsia. He reported six cases with one death.

Schwarz³ in 1923 contributed the most thorough study of vascular collapse in toxemic patients, making the important observation that most of these patients were not of the convulsive but of the nephritic type. He recorded thirteen cases of postdelivery shock among sixty-eight cases of toxemia seen during eleven years, giving the high incidence of 19 per cent for such a serious complication. There were five deaths, a mortality of 38.5 per cent for cases in which collapse occurred.

One of us⁴ has reported experience with postdelivery collapse in patients with chronic kidney lesions and has observed one fatality.

Driscoll⁵ in 1928 reported several cases of obstetric shock with one fatality and feels that the shock that is incident to the delivery of a nephritic patient offers the worst prognosis of any.

One thousand and eighteen cases of toxemia of pregnancy were observed from May 1931 to March 1936 in the Department of Obstetrics and Gynecology of the University of Chicago at the Chicago Lying-In Hospital. Among these patients there have been twenty-six cases showing a drop in systolic blood pressure of more than 70 mm of mercury. There were profound clinical manifestations of shock in addition to the fall in blood pressure in sixteen of these cases, eleven of which were of the chronic and five of the acute type. Energetic treatment followed the occurrence of collapse in all, and yet four patients relapsed into shock a second time and required repetition of the treatment. In only two of these acute cases did it occur within fourteen hours after delivery.

Lesser drops in blood pressure were considered a "normal" phenomenon. One usually sees a fairly marked drop in eclamptic and preeclamptic patients shortly after delivery, with or without a subsequent rise before the blood pressure gradually returns to normal in the puerperium. Therefore, one notes less dramatic drops in eclampsia and not nearly as severe a shock clinically.

ETIOLOGY

There was no excessive hemorrhage in any of these cases. However, vaginal and intra-uterine examinations were made in four to rule out ruptured uterus with massive intra-abdominal hemorrhage. One exploratory laparotomy was done because of symptoms very suggestive of intra-abdominal hemorrhage, but none were found.

The one etiologic factor common to all cases was the toxemia and its manifestations, such as subjective symptoms, hypertension, albuminuria, retinal changes and decreased urea clearance.

In three of the more serious cases collapse occurred prior to delivery. One patient had a typical eclamptic convulsion, a second had an atypical eclamptic convulsion, and the other had a seizure suggestive of a cerebral accident or spasm. The last patient had also suffered a definite cerebral accident in her last pregnancy, with a residual hemiplegia. Delivery itself seems to be the most common associated cause aside from toxemia. All but three patients had their reaction within fourteen hours, and the majority within six hours after delivery. These patients had received hypertonic intravenous therapy, which might have postponed the collapse. One had a persistent hypotension with partial anuria. In the typical case the collapse was associated, as Schwarz has emphasized, with the emptying of the uterus. The idea of shock following sudden and great alterations in intra-abdominal pressure is, of course, not new.

Anesthesia and heavy sedation cannot be universally blamed. Neither was used in some of the worst cases in this series. The former use of powerful depressants, chiefly veratrum viride, was cited by Bailey as a factor in collapse of eclamptic patients.

From the Department of Obstetrics and Gynecology the University of Chicago.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

⁵ Driscoll, W. P. Shock in Pregnancy and Labor. *Anesth. & Analg.* 7: 113 (March-April) 1928.

The absence of hemorrhage, excessive surgical trauma and other common etiologic agents of shock with the presence of an acute strain (labor and delivery) on a chronically strained (toxemia and its hypertension) vascular system leads us to believe that this shock is a vascular collapse. The abdominal support of the gravid uterus is suddenly withdrawn. It may be due to a paralysis and massive ectasia of the splanchnic capillary bed. Vascular spasm has been demonstrated in these toxic cases.

It should be kept in mind that in most of these cases there is a disturbed water balance and altered fluid exchange between extravascular and intravascular fluids may be a factor in producing the collapse. It is also possible that the vasomotor center which has been stimulated may become depressed.

PATHOLOGY

In the few cases of this type that have come to autopsy a chronic glomerulonephritis has usually been observed. There were widespread areas of focal necrosis of the liver in two cases. Further comment on the pathologic changes in these cases is withheld because the number of cases is so small. However, further study of the liver lesion in such cases might prove instructive.

THE CLINICAL SYNDROME

The patient usually sinks into an apathy of shock without any distressing subjective symptoms that would give warning. Occasionally there is nausea, vomiting, epigastric pain and a vague feeling of apprehension. The condition, unless anticipated, is usually detected by the nurse, who notes the weak pulse, the clammy skin, a grayish, slightly cyanotic pallor to the face, or the mild stupor. Examination for hemorrhage is negative and when the blood pressure is taken a tremendous drop is observed. No systolic blood pressure could be demonstrated on the arm for several minutes in many cases in this series. The pulse may not be rapid, as was noted in the type of shock observed by Livingstone, McFetridge and Brunner,⁶ but it may be even too weak to feel at the radial artery. The patient may be quite comatose in a serious attack but can usually be partially aroused. The extremities are cold and moist.

The history is of some aid. In three of our series of sixteen severe cases there had been previous cerebral accidents (with clinical residuum present) in past pregnancies associated with nonconvulsive toxemia. Six patients had eclampsia at some time in their obstetric careers, which probably initiated the renal damage.

The histories of previous pregnancies were available in twelve of the twenty-six cases. In each instance there was such definite evidence of toxemia as convulsions, significant albuminuria or a blood pressure over 165 systolic and 115 diastolic. A reliable family history was obtainable in many instances, and there is some evidence that these patients came from a family stock predisposing to vascular disease. The mother of one patient had died of eclampsia, a sister had had convulsions at childbirth, and a brother had died following a cerebral hemorrhage. The sister of another patient is being treated in our clinic for a severe chronic nephritis complicating a pregnancy. The fathers of two patients died of cerebral hemorrhage. The parents of several other patients died of "heart failure with

dropsy" at more advanced ages. The past histories in six cases revealed scarlet fever with the notes "with dropsy" and "very ill" in two cases. Seven other cases gave the history of severe attacks of influenza, the significance of which is questionable.

The average age in the severe cases is 37.6 years and the parity 3.8, for the milder cases these figures are 29.5 and 2.9, respectively.

In the sixteen severe cases in which the fetal weight is recorded the average is 1,198 Gm with a fetal mortality of 76.4 per cent, showing the hazards for the fetus in such advanced toxemia. When these figures are corrected for hysterotomy and sterilization done early in pregnancy, the average weight rises only to 1,540 Gm, but there is still a fetal mortality of 70 per cent.

Chart 1—Blood pressure tracings of woman aged 43, octipara (five abortions). Toxemia with last two pregnancies. Symptoms: vertigo, vomiting, epigastric pain. Laboratory examination: albumin +++ casts + + + + hemoglobin 14 Gm, cell volume 37. Eyes: hypertensive changes. Delivery: hysterotomy and sterilization. Baby: weighing 890 Gm, died neonatally. Collapse occurred fifty hours after delivery.

Retinoscopy was done in fifteen of the sixteen severe cases, and in eleven, or 69 per cent, there were definite changes showing evidence of a chronic nephritis or hypertension.

FOLLOW UP

All except two of the sixteen patients have been followed from six weeks to over three years. Of these fourteen patients, seven have been observed to have a systolic blood pressure of over 200 mm of mercury and a diastolic of over 120. One suffered an attack of cerebral thrombosis. Six complained of headaches, blurred vision or fatigue, while eight felt well. Six cases showed traces of albumin, one with hyaline casts. Blood chemistry showed no conclusive or consistent changes.

⁶ Livingstone H. M., McFetridge, S. E. and Brunner R. N. Profound Blood Pressure Fall with Bradycardia: a Normal Pulse Rate in Surgical Procedures. Surg. Gynec. & Obst. 56: 917 (May) 1933.

TREATMENT

Prophylactic treatment begins early in the obstetric career of these women. Eclampsia—or, worse, a prolonged state of preeclampsia—should be forestalled by proper medical treatment and the termination of pregnancy if indicated. Successive pregnancies reproduce or aggravate a nephritis and should be avoided or limited. Sterilization by the method of choice for the given case will salvage many years of useful, healthy existence for the patient and her family.

The blood pressure and pulse should be watched closely for several hours after the delivery of a patient with severe (usually recurrent) nonconvulsive toxemia. A tight binder and a small sand bag applied to the

lary, transfusion is not amiss, as these patients often have a secondary anemia.

One should not overlook the possibility of an internal hemorrhage, as from a ruptured uterus. Vaginal examination with careful exploration of the entire parturient canal will determine this as well as detect retained secundines with slow but dangerous seepage of blood and serum. Intra-abdominal hemorrhage may be ruled out by abdominal paracentesis of the more dependent flank or by puncture of the culdesac. Exploratory laparotomy may have a place in rare and confusing cases.

Hypodermic use of ephedrine and solution of posterior pituitary is indicated. The usual treatment of shock from any cause is always in order, such as the

steep Trendelenburg position, external dry heat, caffeine by hypodermic injection or a hot coffee enema. Even binding the extremities toward the torso may be of aid in an emergency. A functional cerebral blood circulation must be maintained.

When the diagnosis is made, the administration of dextrose should be started immediately and if the collapse is profound from 2 to 3 minims (0.12 to 0.18 cc) of 1,000 epinephrine should be injected by hypodermic syringe into the tubing near the vein and the remainder of the 1 cc ampule be emptied into the dextrose flask.

After the initial recovery the patient must be watched for several hours for detection and treatment of a relapse (such as occurred in three of our most serious cases).

The urinary output is an important guide to prognosis, especially as a partial anuria is a secondary danger that the patient faces after recovery from the

initial collapse. If this occurs the hypertonic dextrose solution may need to be increased from 20 to 30 per cent, or even to 50 per cent, to obtain a satisfactory urinary output.

MORTALITY

One fatality occurred in our series.

A woman aged 28, a septipara, who was admitted to the hospital in convulsions in the thirty-fourth week of gestation, had chronic nephritis of several years' duration, she had had convulsions during a previous labor and had a definite familial history of vascular-renal disease. The vascular collapse took place six hours prior to delivery and eight hours before death.

Several other patients were in a very critical condition.

One patient with a milder collapse has since died of uremia and cardiac failure with autopsy signs of chronic glomerulonephritis. Another patient in this group has been hospitalized in the medical clinic because

Chart 2—Blood pressure tracings of woman aged 39, quintipara (two abortions). Scarlet fever ten years before father died of cerebral hemorrhage. Symptoms: headache, scotomas, epigastric pain, vertigo. Laboratory examination: albumin + + +, occasional cast, hemoglobin 15.5 Gm, cell volume 44. Eyes: hypertensive changes. Delivery: spontaneous, vascotomy performed on husband. Baby weighing 1,660 Gm survived. Collapse occurred five hours after delivery.

abdomen may compensate for the pressure of the previously gravid uterus and prevent a collapse.

Active Treatment—Prompt treatment in the event of a collapse of the blood pressure, will be required to save the patient if the systolic pressure remains below 60 mm of mercury for any length of time. One should not wait for this to occur. Prolonged anoxemia is followed by a severe acidosis and irreparable damage to the brain. Hypertonic intravenous dextrose of 20 per cent, and occasionally 30 per cent, is the best agent to raise the blood pressure. Acacia, 30 Gm, with 4.5 Gm of sodium chloride in 100 cc ampules diluted to 500 cc with freshly distilled water, given intravenously, is useful. A hypodermoclysis of not too great an amount may be started early, but isotonic dextrose rather than sodium chloride should be used in these patients. Blood transfusion may be needed, as the serum proteins exert a more prolonged osmotic effect to pull and hold fluids in circulation. As a corol-

of continued hypertension, headaches and hypertensive retinitis but is still living. It would seem that the normal life expectancy of at least half of these patients is definitely reduced.

We have been able to add to our twenty-six cases twenty-four similar ones from the literature and from other sources, wherein there were nine deaths. The total mortality for the series of fifty cases was 20 per cent. Wegner of the Department of Obstetrics and Gynecology of Washington University School of Medicine has reviewed the cases occurring at the St. Louis Maternity Hospital and has found twenty-one among 231 cases of toxemia, an incidence of 7.66 per cent. There was one death giving a mortality of 4.76 per cent. There is therefore a combined incidence in 1,249 cases of toxemia at the St. Louis Maternity Hospital and the University of Chicago Clinics of forty-seven cases, or 3.76 per cent. Including these cases, through the courtesy of Schwarz and Wegner,⁷ a total of seventy-one cases of this type have been observed. The gross mortality for the entire series is 15.49 per cent. There is no doubt that some of these patients will die in spite of the best therapy. This is evidenced by the

CONCLUSIONS

- 1 Parturitional vascular collapse is a grave condition occurring typically in a rather small percentage of elderly multiparas who have been afflicted with a progressively severe nephritis in succeeding pregnancies.
- 2 The incidence of this condition in our clinic was 0.2 per cent of all deliveries and 2.55 per cent of all toxemic patients.
- 3 The toxemia seems to be the most important etiologic factor, with delivery definitely exciting the appearance of vascular collapse.
- 4 The blood pressure and general condition of cases of severe and chronic toxemia should be watched closely for twelve hours after delivery. Equipment and personnel should be ready for prompt and effective treatment in the event of the collapse of such a patient.

Drop in Systolic Blood Pressure in Twenty-Six Cases of Nephritic Preeclamptic and Eclamptic Toxemia

| Drop in Systolic Blood Pressure in Mm. Hg | Number of Cases | Type of Toxemia | | | Type of Delivery | | | | | |

fact that in our clinic and also in that of Schwarz and Wegner a low mortality has occurred in spite of every known therapy being employed. However, because our cases have responded to the treatment outlined and because Schwarz and Wegner have (by practically identical therapy) reduced the mortality strikingly (from 38.5 per cent to 4.8 per cent) from that of the earlier cases reported in 1923, one is led to believe that the treatment available at present will definitely lower the death rate.

The gravity of this obstetric accident may be appreciated from the foregoing statistics. Most of these patients received proper treatment, and without this the mortality might have been higher. We agree with Driscoll that this type of obstetric shock carries the gravest prognosis of any obstetric complication, excepting probably that of a ruptured uterus.

It is surprising that more attention has not been given to this condition. It is, in our opinion, an accident as dramatic, more urgent and more fatal in itself than eclamptic seizures, but, because less common, it has not received so much consideration. Many conditions are probably more rare, such as abdominal pregnancy, and yet have been much more prominently mentioned in the literature.

⁷ Wegner C. R. Personal communication to the authors.

Chart 3—Composite blood pressure tracings in sixteen cases

5 The mortality is high, 15.49 per cent of seventy-one cases reported. The condition is an entity deserving of recognition and further study because of its gravity and because proper treatment should reduce the mortality appreciably.

6 The most common pathologic lesion was a chronic glomerulonephritis. The liver lesions in these cases may merit further study.

7 Proper use of hypertonic intravenous dextrose solution forms the basis for effecting recovery from the shock. A secondary partial anuria, associated with hypotension, may require management.

5848 Drexel Avenue

ABSTRACT OF DISCUSSION

DR RALPH R. WILSON, Kansas City, Mo. I wish to emphasize that toxemias with hypertension are not the only ones subject to circulatory collapse. I refer especially to that group which is characterized by hypometabolism, hypotension and general asthenia. Their labors are usually rather asthenic. Near term they often present edema out of proportion to

related symptoms. By some they have been designated as "low kidney reserve." At any rate they represent a chronically exhausted circulatory system and are prone to collapse. At this point I wish to bring out the observation that often a delayed placental expulsion is an early indication of approaching shock, delay being due to incidental uterine inertia. Since the report of Titus and his co-workers relative to the pre-operative administration of concentrated dextrose, I have adhered to that practice rather rigidly. As to the type of toxemias occurring in successive pregnancies and associated with pronounced hypertension, it is logical to assume a mechanism somewhat different. The actual mechanism, however, of either the low pressure or the high pressure toxemias still remains rather speculative until more is known about capillary physiology. Damage to parenchymatous structures may be extensive before blood studies of the central circulatory system can indicate it. With the fulminating type of toxemia the act of delivery must be considered actually one of decompression, and it is subject to the same dangers as any decompression, if performed too rapidly. In my opinion, intravenous administration of concentrated dextrose made up in distilled water is the best measure. Sodium chloride is contraindicated because these patients are subject to urinary suppression and they do not handle the salts well. In addition to the liver and kidney lesions found at autopsy, I have been impressed with the frequency of hyperplastic developments of the heart and greater blood vessels, as well as of those of the adrenals and the thyroid. In a routine manner the following conditions must be excluded: ruptured uterus, inversion of the uterus, concealed hemorrhage, hypertrophy with acute dilatation of the heart, cerebral accidents, acute dilatation of the stomach, and even diabetic coma.

DR. R. D. MUSSEY, Rochester, Minn. These interesting data on the occurrence of vascular collapse following delivery of women who have hypertensive toxemia indicate that the disturbed mechanism of the arteriolar vessels is widespread throughout the body, even in cases in which the renal lesion is most prominent. This has been shown by evidence obtained by a study of vessels of the nail folds, of the ocular fundi, of muscle tissue obtained by biopsy from patients who are suffering from toxemia, and by examination of the glomerular and other vessels of such patients who have died. The nature of the arteriolar involvement has been demonstrated by repeated examination of the ocular fundi in cases of advancing hypertensive toxemia of pregnancy to be a spasm of the arterioles, which may vary from day to day early in the disease, later, as the hypertension increases, injury to the vessels is indicated by a general narrowing of the lumen and by edema and sometimes by hemorrhage into the surrounding tissues. When this injury is superimposed on vessels already damaged, these vessels are rendered more spastic and less elastic than are the vessels of women who have acute toxemia without previous arterial or renal injury. Allen and McQuiston have reported 350 cases in which persons who had a systolic blood pressure of 180 mm of mercury or more were subjected to major surgical operations. As a result of their observations the authors concluded that patients of both sexes with all grades of hypertension, without obvious or with mild myocardial and renal insufficiency, withstood operation as well as did those without such hypertension. In approximately three fourths of the cases of vascular collapse reported by the authors, the patients had preexisting arterial or renal damage. Vascular collapse that occurs after delivery of patients who have toxemia and chronic arterial damage may be explained by the sudden release of intra-abdominal pressure at a time when the walls of the arterioles have lost the elasticity by which sufficient blood pressure is maintained in the general circulation. This paper serves to emphasize the importance of prophylactic treatment. If a woman is found to have definite evidence of chronic nephritis or evidence of well marked arterial injury, measures should be taken to prevent pregnancy or to terminate pregnancy if the condition is discovered early in gestation. Later in the pregnancy, the avoidance of operative trauma associated with sudden release of intra-abdominal pressure, when possible, is highly desirable.

Clinical Notes, Suggestions and New Instruments

SPOROTRICHOSIS OF THE CERVICAL AREA

GILBERT M. LOEWE, M.D., WINNETKA, ILL.

Reports of sporotrichosis of the skin are common in the literature but of involvement of other tissues less frequent. The case in this report occurred in the anterior cervical area, beginning as a deep seated infection, with no apparent portal of entry, was not diagnosed for thirteen months, with able counsel, and did not respond to the customary medication.

Because of the long duration of this case, numerous investigative procedures were employed. For the sake of brevity only the essential data are recorded here.

A. N. L., aged 30, wife of a physician, was in excellent health until December 1931. She was visiting in Montgomery, Ala., where she developed a rather severe rhinitis. Following this attack a pea-sized nodule was noted in the region of the right anterior cervical gland. This nodule gradually increased in size and tenderness for a period of two weeks, when fluctuation was present, accompanied by chills and fever. At this time the tumor was incised, deep penetration being necessary, and about one ounce of grayish thick pus was obtained. Cultures and animal inoculation of this material failed to disclose any causative organisms. The incision failed to heal and there became established a small sinus, which appeared to lead to an underlying indurated, indolent mass, which was fixed to the overlying skin but movable above the underlying tissue. This tumor was about the size of a small hen's egg.

The patient's condition remained stationary until the following March, when the swelling increased markedly in size, involving the major portion of the right side of the neck and part of the face. There occurred at this time attacks of intermittent fever and chills. This condition continued for two months and on May 6 a biopsy was performed. The tissue was submitted to several competent Chicago pathologists, who considered the lesion to be a "chronic granuloma, probably of mycotic origin." For the following six months, though the patient's general health was relatively good, there was little change in the local condition. Potassium iodide was given in dosages amounting to as high as 270 grains (17.5 Gm.) daily. X-ray and quartz light therapy were employed at various times. A large number of local treatments were administered and nucleotide and gold sodium thiosulphate were also given. All these therapeutic measures were tried at various times with no effect on the local condition. During this period the patient was seen by many leading consultants in the Middle West. Diagnosis consisted of almost all the known chronic granulomas, those most seriously considered being tuberculosis, Hodgkin's disease and a mycotic infection. The treatment that was advised naturally varied widely. It consisted of the measures mentioned and also of radical excision and exploration of the involved area. November 19 an extension of the process posteriorly to the sternocleidomastoid was drained. The pus from this yielded a hemolytic streptococcus.

In February 1933 the patient was seen by Dr. Harold Amoss and his associates W. D. Forbus and D. T. Smith. They were able by means of bacteriologic studies of the discharge to isolate a sporothrix and a beta hemolytic streptococcus. Sporotrichosis was the first of many clinical diagnoses to be confirmed by laboratory observations. On their advice ethyl iodide inhalations were attempted but they were so poorly tolerated that they had to be discontinued. Increasing doses of autogenous sporothrix vaccine, streptococcus vaccine and streptallergen were administered subcutaneously. Shortly after this treatment was begun there was a striking though not complete regression in the size of the mass, the sinuses and the amount of discharge.

The sinuses continued to drain a scant amount of seropurulent material until April 1934. At this time my attention was called to Dr. Levine's report on the use of phenylmercuric nitrate for the treatment of mycotic infections. On Dr. Levine's suggestion irrigations of phenylmercuric nitrate 1:30,000 and application of 1:1,500 ointment were used twice daily in con-

1. Personal communication to the author from Dr. Benjamin Levine of Cleveland.

junction with the irrigation of the sinuses once daily with dilute solution of sodium hypochlorite. The change following this treatment was spectacular and by June 6, 1934, the indurated mass had almost entirely disappeared while the sinuses were completely closed. There has been no recurrence or discharge since that date and the condition has apparently remained cured.

The causative organism is a species of *Rhinodermum*, which in 1898 was classified by Schenck² as *Sporotrichum*. It is usually characterized according to Lawless³ by various sized subcutaneous nodules and nodules with associated lymphangitis which may soften enlarge and involve the skin in an ulcerative process or undergo spontaneous healing. The differential diagnosis between sporotrichosis, syphilis and tuberculosis is sometimes difficult and on this basis lies the importance of the treatment.

Four clinical manifestations of the disease are most commonly described:

1 The localized lymphatic form with (a) sporotrichotic chancre and (b) lymphangitis

2 The disseminated and generalized forms with (a) gummatous or (b) ulcerative lesions. This type resembles syphilis

3 The hemogenous form, which involves bone, synovial membrane, the testicle and so on most commonly with or without an associated inflammatory skin involvement. Any portion of the body may be affected

4 Mucous membrane involvement found most commonly in the mouth, pharynx, larynx and trachea

Mount⁴ believes that transmission through unbroken mucous membrane is possible and that man is a passive carrier as he has found the sporothrix in the pharynx as a saprophyte. Davis⁵ has shown that *Sporotrichum* may be carried through the intact intestinal mucosa by the migratory phagocytes. Animals are frequently named as carriers.

A biopsy is of material assistance but the discovery of the specific organism is the only positive method of definite diagnosis. Direct smears, cultures on Sabouraud's medium and hanging drop examination of the pus should be used. Seroagglutination and complement fixation tests and also cutaneous and intracutaneous reactions may be of value.

The case here reported presents several possibilities:

1 The original acute pharyngeal infection with secondary involvement of the cervical lymph node may have been due to *Sporothrix*. No local lesion, however, developed in the throat and the teeth were found to be normal by direct and roentgenographic examination.

2 The primary infection of the pharynx and cervical node may have been due to a pyogenic organism with later localization of the sporothrix in the damaged node.

3 The process may have been a suppurative one until drainage to the exterior was established with entry of the sporothrix through the external sinus.

SUMMARY

1 In a case of sporotrichosis, the duration of which was more than two years, the etiologic agent was not discovered until after the patient had been seen by more than fifty competent consultants among whom there were seventeen noted pathologists who examined the tissue.

2 Many forms of therapy were advocated; radical excision of the affected area was advised by three competent consultants.

3 The orthodox therapy of iodides for sporotrichosis was ineffective. Specific autogenous vaccines were apparently effective and produced a marked improvement in the local condition. The residual lesion responded to phenylmercuric nitrate and dilute solution of sodium hypochlorite.

4 The patient has remained cured for more than fifteen months.

5 The importance of proper bacteriologic investigation of chronic suppurative lesions is strikingly illustrated by the history of this case.

MYELOGENOUS LEUKEMIA WITH CUTANEOUS INVOLVEMENT

S M GOLDHAMER M D AND B F BARNEY M D ANN ARBOR MICH
Assistant Professor of Medicine and Instructor in Dermatology
Respectively University of Michigan Medical School

True myelogenous leukemia with cutaneous involvement is a relatively rare clinical entity, only sixteen cases having been reported. The early literature has been reviewed by Barney¹ and Hollander, Kastlin, Permar and Schmitt² who added two additional cases. Since the publication of these reports one case has been described by Patrassi.³

The case here reported was diagnosed as cutaneous myelosis and the clinical observations were substantiated by subsequent biopsy and autopsy studies.

REPORT OF CASE

R C a white man, aged 41 on admission to the Simpson Memorial Institute Aug 11, 1933, complained of pain in the left upper quadrant. Since January 1933 he had noted increasing weakness, palpitation and dyspnea on exertion. More recently a constant pain was present in the left upper quadrant.

Fig 1—Gross appearance of nodules at time of autopsy

One month previous to admission the patient accidentally noted a mass in this region. He had had hemorrhoids for two years but noticed that they had been bleeding more readily for the past three weeks. In addition there were many spontaneous 'black and blue spots' appearing on the skin.

The patient was well developed and well nourished; he was obviously ill but not acutely so. The superficial veins were quite noticeable and many purpuric areas were present on the right leg. The skin was deeply pigmented over the exposed surfaces. The conjunctivae were pale. Many hemorrhagic spots were present on the buccal mucosa. The spleen occupied the entire left side of the abdomen. The liver edge was palpable 7 cm below the costal margin. In addition there was marked generalized lymphadenopathy.

The laboratory data were as follows. The Kalm test of the blood was negative. The basal metabolic rate was +45 per cent, with a pulse rate of 76 on two determinations. Stool examinations were consistently "negative." Repeated urine specimens showed an occasional trace of albumin. X-ray examinations of the chest revealed essentially normal lungs. The blood picture showed 2,630,000 red cells per cubic millimeter

Fig. 2—Low power magnification of entire nodule

122,800 white cells per cubic millimeter and hemoglobin 5.32 Gm per hundred cubic centimeters (38 per cent Sahli). The differential count was as follows: adult polymorphonuclear leukocytes, 30 per cent, young polymorphonuclear leukocytes, 19 per cent, metamyelocytes, 6 per cent, myelocytes, 11.5 per cent, blast cells, 16 per cent, eosinophils, 6 per cent, eosinophilic myelocytes, 5.5 per cent, basophils, 2 per cent, large lymphocytes, 2 per cent and small lymphocytes, 2 per cent. With a few minor variations due to the progress of the disease, these blood determinations were similar to those noted subsequently (100 observations).

The patient was in the hospital on six different occasions from Aug. 8, 1933 until his death Dec. 23, 1934. During this period he received such treatment as roentgen therapy to various portions of the body, solution of potassium arsenite by mouth, transfusions and other supportive therapy. Although these measures occasionally resulted in symptomatic improvement no definite progress was made in altering the course of the disease.

Dec. 4, 1934 the patient was examined by a member of the department of dermatology. There were three half cherry sized nodules seen in the skin on the right wall of the chest and a similar number over the right tibia. These lesions were discrete, attached to the overlying skin but not bound to the underlying structures. They were firm, not tender, circumscribed and rubbery in consistency. The skin over them was dull, erythematous. There was no evidence of hemorrhage. Subsequent to this examination other split-pea sized nodules appeared in the aforementioned areas. No definite history of trauma was elicited at the sites at which the tumors appeared. The radiosensitivity of the tumors was not determined.

A picture taken at the autopsy shows clearly the nodules on the chest (fig. 1).

HISTOLOGIC STUDY OF NODULE (BIOPSY)

The section studied was from a nodule on the chest. This was fixed in solution of formaldehyde and stained with hematoxylin and eosin. There was an infiltration of myeloid cells in nodular formation located deep in the corium overlying the adipose tissue. The papillae showed no definite infiltration nor did the more superficial layers of the corium. The epithelium appeared atrophic and there was a decrease in the sebaceous and sudoriferous glands apparently from pressure. The infiltrate for the most part was sharply demarcated and

surrounded by a fibrous capsule. Within the blood vessels was seen the blood picture of myelogenous leukemia (fig. 2).

The cells of the infiltrate were large, pale-staining mononuclear cells, some of which contained granules and others were agranular. Interspersed between these were stroma or fibrous tissue cells. Schultz's stain for oxidase granules was positive (fig. 3).

AUTOPSY REPORT

A complete postmortem examination was carried out. Both grossly and microscopically, the bone marrow, lymph nodes and spleen were entirely replaced by "leukemic" cells while the thymus showed partial replacement. In the heart the vessels

Summary of Reported Cases

| Case | Author | Age | Sex | Duration | Site |
|------|--|-----|-----|----------|--------------------------|
| 1 | " | 18 | ♂ | | Trunk and arms |

were surrounded by a leukemic infiltrate, and the liver, adrenals and kidneys showed various sized nodular infiltrates. The gross and microscopic skin changes were the same as those noted previous to death.

COMMENT

In the sixteen cases that have been recorded in the literature previous to this report, the interval between the appearance of the cutaneous manifestations and death was very short, as shown in the accompanying table. The time varied from eleven

Fig. 3—High power magnification of lesion

days to four months and averaged sixty-four days. In the case here presented it was noted that subsequent to the cutaneous eruption the patient's condition became markedly worse and death ensued three weeks later. It is thus apparent that skin manifestations appear late in the disease. Therefore when cutaneous involvement does occur the expectancy of life is commonly measured in weeks.

All cases presented in the literature have shown essentially the same cutaneous changes. The eruption appeared as nodules varying in size from a glass-headed pin to a cherry and in color from that of normal skin to deep purple. The sites of predilection were the skin of the trunk (particularly the anterior surface of the chest), the extremities and rarely the face and mucous membranes. As a rule these nodules were unaccompanied by local symptoms.

RAPID GROWTH OF A LARGE BREAST FIBROMA IN A YOUNG GIRL

BENJAMIN MARKOWITZ, M.D. AND H. L. HOWELL, M.D.
BLOOMINGTON, ILL.

This case is of interest only because of the extremely rapid growth of a large breast tumor in a girl, aged 14 years. While the Cohnheim theory of the origin of such tumors arising from misplaced islands of tissue is in many instances doubted, it is difficult to explain this case on any of the other theories.

This girl had normal appearing, symmetrical breasts with no evidence of nodule formation in February 1935. Sometime

responsible for the enlargement. The tumor was very hard, rounded and freely movable underneath the skin, with no involvement or dimpling of the nipple. It was thought that a line of demarcation could be detected between the tumor and the breast tissue proper. The superficial veins particularly

Fig 1—Appearance of patient before the operation July 11

during April she began experiencing a 'heaviness' of the right breast and noted that the nipple areola on this side appeared wider. Sometime in May she noticed that the entire right breast was larger than the left, and the 'feeling of heaviness' was increased. For relief her mother made her a 'carrier' to help support this breast. From this time on the breast grew very rapidly. Within two months from the time the patient first complained of symptoms the right breast was described as twice as large as the left. Figure 1 shows the inequality in size found within three months from the very first complaint.

REPORT OF CASE

History—The only important factor in the history is the emphasis on the rapidity of growth of the tumor. There was no history of trauma, no disturbance during puberty, no menstrual disturbances, no pain except the 'feeling of heaviness' and no history of any inflammatory process. The appetite was good and there was no loss of weight.

Physical Examination—On physical examination, July 5, the patient was well developed and healthy appearing. The right breast was tremendously enlarged, extending slightly below the waistline. On palpation a large tumor involving the entire circumference and anterior pole of the breast was found

Fig 2—Appearance of patient after the operation August 17

around the nipple and the areola were enlarged and engorged. The axillary lymph glands were not palpable.

Operation—July 11, the day of operation, we felt that the breast had increased in size since July 5, the day of examination. An incision about midway between the natural chest fold

Fig 3—Microscopic section of removed tumor

and the nipple was made in the lower surface of the breast in preference to a flap incision at the natural crease. The tumor was only slightly attached by delicate adhesions which were easily freed with the finger. Removal was very easy with minimum trauma to the breast. The small hemorrhage was easily controlled and the skin closure was readily accomplished.

A small wick drain was left in the outer angle. Healing took place very rapidly by first intention. By August 17 the operated breast had made a very rapid approach to normal (fig 2).

Pathologic Examination—The specimen consisted of a single rounded, somewhat oval, encapsulated tumor mass about the size of a fetal head. The surface was quite smooth and the consistency rather soft. The cut surface was a bluish gray, somewhat resembling sarcoma, measured 14 by 11 cm, everted slightly and was very moist, with thick, mucus-like material which accumulated in small cystlike spaces and rounded depressions.

Microscopically there was marked overgrowth of both fibrous and epithelial elements. The acini and ducts were quite numerous, and in many areas the acini were lined by several layers of cells. The fibrous stroma was edematous and hypertrophied (fig 3).

The diagnosis was benign fibro-adenoma with myxomatous changes.

COMMENT

Many authors maintain that inflammation is responsible for the origin of many of the simpler fibro-adenomas. Some assert that it is impossible to establish a definite demarcation between the cystic changes of so-called mastitis or mastopathy and fibro-adenomas. Various stages of the growth of diffuse adenofibrosis may be found within chronic mastitis. Ewing believes that tumor-like areas found in chronic mastitis show many inflammatory changes.

In the case here reported we are evidently dealing with a true tumor arising in breast tissue with a predisposition in the form of superfluous or misplaced material.

INJURIES OF THE HAND

CLINICAL LECTURE AT KANSAS CITY SESSION

SUMNER L. KOCH, M.D.

CHICAGO

Why should there be many varied opinions among medical men as to what constitutes the most adequate and effective treatment of a compound injury, whether it involves the hand or some other part of the body? Much of this difference of opinion is due to the fact that we have often lost sight of basic surgical principles and concentrated our attention on details of treatment. In ignoring principles we have sometimes been led to utilize methods which retarded or actually defeated the recovery we desired to hasten.

What are these surgical principles which form the basis of logical treatment?

- 1 The first law of surgery *nihil nocere*—to do no harm
- 2 Not to leave contaminated tissue in the injured area
- 3 To avoid so far as possible leaving foreign bodies buried in the tissues
- 4 To close every open wound as soon as it can be done with safety
- 5 To put injured tissues at rest.

TO DO NO HARM

What does "Do no harm" mean? It means first, to avoid every form of injury—mechanical, thermal, chemical, and, secondly, not to add contamination to that which is already present.

Why is trauma so important and why did one of America's greatest surgeons, William S. Halsted, lay

so much emphasis on avoiding it? Living tissue is delicate, fragile substance. The covering tissues of skin and mucous membrane have acquired some resistance to injury and a certain adaptation to contact with the outside world, the deeper tissues have little resistance to injury. As Petersen¹ says and as many others have pointed out, as medical students our first conception of body tissues results from continual observation of fixed, hard, immobile structures: the cadaver in the dissecting room, the formaldehyde hardened specimen in the histology and pathology laboratory, viscera and tumors and extremities in glass jars, preserved for indefinite periods. In our early surgical training we fail to recognize the sensitiveness and susceptibility to injury of living body cells, for anesthesia has blunted the sharp edge of pain, and in our desire to be helpful and efficient assistants we are often unwittingly ruthless in our forceful retraction and manipulation of this fragile, delicate living substance.

Our first task in the treatment of the injured hand—and because of the limitation of time I must ignore here the treatment of the patient in shock and omit any discussion of the careful preliminary examination of the patient to determine as accurately as possible the extent of his injuries—is often the arrest of hemorrhage. It should be done without adding trauma or without adding contamination. For persistent oozing, gentle manual pressure over the bleeding surface with a handful of sterile gauze is often all that is necessary. If a single spurting vessel can be seen, it can be caught with a sterile forceps and the hemostat left in place. If bleeding is profuse, an ideal method of arresting it is always at hand: the blood pressure band inflated to 250 mm of mercury and used as a constrictor. I have never seen nerve palsy resulting from the use of a blood pressure band as a constrictor but have often seen injury of soft tissues and nerves from the ordinary constrictor powerfully applied and have too frequently seen evidence that infection was introduced into an open wound from the needless attempt to ligate bleeding vessels under unsuitable conditions.

NOT TO LEAVE CONTAMINATED TISSUE IN INJURED AREA

The next step is preparation of the operative field. Whether the injury is extensive or slight, the method is identical. While the patient is being anesthetized for with extensive injuries a general anesthetic is always used, the surgeon and his assistants scrub their own hands. The one who finishes first dries his hands, puts on sterile gloves and prepares the field of operation. If the injury is a very serious one I prefer to prepare the patient myself for it is difficult to tell in words to a beginner in surgery what one means by adequate preoperative cleansing. With the wound itself covered with sterile gauze and with the blood pressure band inflated to prevent bleeding a wide area about the wound is first shaved and then cleansed with soap and water. If the part is covered with greasy dirt a preliminary cleansing is carried out with benzene or ether and this in turn followed with soap and water. If the preoperative examination indicates that the median or ulnar nerve has been divided, the preparation includes the entire forearm and lower third of the

From the Department of Surgery, Northwestern University Medical School.

Read in the General Scientific Meetings at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 12, 1936.

¹ Petersen, W. F. *The Patient and the Weather*. Ann Arbor: Edwards Brothers, 1935, p. xiv (preface).

arm so that if necessary the dissection can be carried above the elbow. When the part about the wound is cleansed the wound itself is uncovered and very patiently, gently and thoroughly cleansed with soap and water. With deep and irregular wounds the edges and deeper tissues are separated with sterile retractors so that there is no doubt that the cleansing process has been applied to every part of the wound which has been exposed to contamination. Finally the soapy solution is washed away with sterile water or salt solution. No antiseptics of any kind are used in the open wound, for I believe that none of them are necessary and that some of them destroy living tissue and do the harm we are trying so hard to avoid.

Without wishing to put undue emphasis on this controversial question I would mention only two facts: antiseptics are of two types, bactericidal and bacteriostatic. Those which are actually bactericidal kill living tissue as quickly as they kill bacteria. The destructive action of phenol on living tissue and of tincture of iodine on a sensitive skin need only be mentioned to recall to mind the many clinical observations every sur-

ments have been applied to catgut ribbons, to raw catgut strings, as well as to artificially infected catgut.

The chemical compounds used in this research study included mercurochrome, mercuraphen, merthiolate, metaphen, potassium-mercuric-iodide, hexylresorcinol, tribromoresorcinol, orthophenylphenate, ethylhydrocupreine, tribrometanaphthal, copper cyanide, copper chloride, copper sulfate, copper sulfate plus methylene

Fig 1 (case 2)—Diagram indicating extent of injury. (Solid black lines represent tendons.)

geon has made on this point. The effect of these and other bactericidal agents on the fragile and delicate tissues underneath the body surface, which have never come in contact with the outside world and have little resistance to trauma, I can leave to the imagination. With reference to bacteriostatic agents, and this group includes many of the antiseptics so widely advocated today, I need only call attention to the careful investigation of Ralph O. Clock² reported in a paper entitled "The Fallacy of the Chemical Sterilization of Catgut Sutures."

He says, in part, in a summary of his work:

In this investigation, which extended over a period of two and one half years, several thousand catgut sutures were prepared from 334 lots of catgut. Twenty-seven different chemical compounds were used for treating these various lots of catgut under a wide variety of conditions, in an attempt to bring about chemical sterilization. The various chemical treat-

Fig 2 (case 2)—Result of immediate suture of all long flexor tendons of thumb and fingers and of median and ulnar nerves twelve weeks after injury and operation.

blue zinc sulfate, peppermint oil, oil of tea tree (*Melaleuca alternifolia*), hydrogen peroxide, malachite green, pyridium, iodine, iodine plus potassium iodide, myodine, parachlormeta-cresol, diacetylmethylmercuriothocresol, parachlorphenol and chlor-thymol ester.

Fig 3 (case 6)—Crushing injury of hand with destruction of skin and subcutaneous tissue and injury of extensor tendons treated by soap and water cleansing, tendon repair and immediate closure of wound with free full thickness graft.

Bacteriologic tests, applied to commercial catgut sutures containing a large amount of a mercury compound have shown that arrested development of bacteria within the catgut is brought about through the bacteriostatic action of the mercury.

² Clock, R. O. The Fallacy of the Chemical Sterilization of Catgut Sutures. Surg. Gynec. & Obst. 56: 149-161 (Feb.) 1933.

compound. These tests have also proved that removal of the mercury compound from the sutures by means of a suitable neutralizing fluid, reactivates the bacteria, which then are able to grow in the culture medium.

None of the twenty-seven chemical compounds studied in this investigation was found to have reliable or uniform sterilizing action on catgut for in no case did all lots of sutures, sterilized with any one of the chemicals or a combination of the chemicals prove to be entirely free from living bacteria.

If antiseptics were necessary it would not be logical to use substances which simply produce bacteriostasis and leave bacteria free to multiply when the dye that fixes them for a time is neutralized or diluted by body fluids. It has often seemed to me that many people today are expending a great amount of effort and ingenuity to drag the surgeon back into the bygone days of antiseptics instead of helping him to go forward in the modern world of asepsis.

Perhaps you will ask, 'Does any one contend that he can render a contaminated wound sterile by soap and

during the World War, and we follow practically the technic described in all our work. Why talk about it when there are many more important subjects to discuss?' If this is your attitude I can only say that you are in the minority, and that you have been too long silent about your practice and your beliefs. As far as my observation goes, the facts that antiseptics are unnecessary and that many of them produce chemical trauma and render wound healing more difficult are either not known to many men or are ignored in their practice.

When the preparation of the operative field and the wound is completed, the next step is excision of hopelessly injured tissue—debridement. This procedure needs no comment. It is sound surgical practice. It should be done with care and discretion, and without needless sacrifice of living tissue.

The next step is repair of injured tissues—reduction of fractures, repair of divided and torn joint capsules, suture of divided tendons and nerves. These pro-

Fig. 4 (case 6)—Result two years after injury

water cleansing?" I do not contend that for one moment. My belief is that if the surgeon sees a patient with a contaminated wound shortly after injury and before infection takes place, in other words before bacteria have begun to invade and destroy tissue, in the great majority of cases he can cleanse the wound and render it surgically clean so that it can be closed and can heal by primary union. The wound area is usually not sterile, but it has often been demonstrated that wounds can heal by primary union if bacteria are not too numerous and not too virulent, if hemostasis is complete and if the tissues about the field of operation have not been unduly injured. The most striking proof of this statement is the frequently demonstrated fact that the washings of 'clean wounds'—i. e., wounds made by the surgeon in the operating room—frequently show bacterial contamination and yet these wounds heal by primary union.

Perhaps you will say again. These facts were known to us long ago. They were demonstrated repeatedly

cedures also need little comment. Each one must be done with exactness, with care, and with a minimum of trauma. Repair of such tissues is not minor surgery, nor a procedure that can be carried out single handed in an office or a ward dressing room. Knavel often said he would rather have the average surgeon operate on him for acute appendicitis than for repair of a divided flexor tendon. That such procedures, however, are often regarded as minor surgery accounts in part for the poor results so frequently obtained.

TO AVOID LEAVING FOREIGN BODIES BURIED IN TISSUES

In repairing injured tissues, consideration of the third principle—to avoid so far as possible leaving foreign bodies buried in living tissue—means abstaining from the use of metal plates or other means of internal fixation in the treatment of fractures, avoiding heavy suture material such as kangaroo tendon, heavy catgut and braided silk and utilizing for ligatures and

for repair of joint capsules of tendons and of nerves the finest and thinnest silk that will accomplish the desired end

TO CLOSE WOUNDS AS SOON AS IT CAN BE DONE WITH SAFETY

The injured tissues having been repaired the next step is closure of the wound. If I were to ask you when operating on a hernia you insist on closing the

Fig. 5 (case 7)—Crushing injury of hand with destruction of covering tissues tendons and part of metacarpal bones treated by immediate soap and water cleansing and early application of pedunculated flap from thigh. Above hand immediately after injury. Below hand underneath flap.

wound after the abdominal wall is repaired you would reply, and correctly, that if it were left open infection would inevitably enter the wound from without and such infection might well be disastrous. At best, healing would take place slowly with great expense of time, of money and of comfort to the patient. Finally there would remain an extensive and contracting scar as a permanent liability and disability. Each of these arguments applies with undiminished force to the accidental wound which our patient has sustained. The great majority of wounds which are seen immediately after the injury is sustained can be closed with safety if the preoperative preparation is adequate and atraumatic. If the wound can be closed with safety there are many sound reasons for doing so. In cases in which the surgeon is doubtful as to whether the preoperative cleansing has converted the contaminated wound into a clean surgical wound he can pack the cleansed wound lightly with gauze impregnated with some nonirritating material as petrolatum or liquid petrolatum and wait for twenty-four hours before closure is completed. At the end of that time closure will be somewhat more difficult because of edema and infiltration of the tissues, but it will still be possible and one will have the advantage of twenty-four hours time to demonstrate the presence or absence of infection of the wound

If there has been extensive destruction of overlying skin and subcutaneous tissue at the site of injury, one still cannot disregard the primary surgical principle of wound closure. It is the same principle that is constantly utilized in the present-day treatment of burns and for the practical application of which we are under everlasting debt to Davidson, a surgeon who taught us how to cleanse and close extensive wounds in which not all of the covering tissue had been destroyed. If all the covering tissue has been destroyed as a result of serious injury, a substitute can often be obtained from some other part of the body—as a graft of intermediate thickness a free full thickness graft or a pedunculated flap, and the much desired objective—immediate closure of the wound—still be attained.

TO PUT INJURED TISSUES AT REST

I need only mention the last principle—rest of injured tissues. Hugh Owen Thomas the uncle of Sir Robert Jones and the father of orthopedic surgery, stressed it continually in his teachings. Every surgeon recognizes its importance in connection with the treatment of fractures. He does not always remember that rest in the early stages of treatment is equally applicable and helpful in the treatment of fractures of tendons of nerves and of covering tissues.

Finally, you may say, This sounds very well in the lecture room, but we would like to see evidence that these theories work out in practice. I wish I could take you back with me to No. 18 General Hospital between Etaples and Boulogne in northern France, and show you how in the last year of the war wounded men came from the British casualty clearing stations

Fig. 6 (case 7)—Appearance of hand eleven weeks after injury.

with extensive wounds of every part of the body which had been cleansed excised, often sutured, sometimes usually because of the pressure of work, lightly packed with gauze saturated in paraffin and left open for twenty-four or forty-eight hours until the surgeon at the base hospital could close them. I wish I could show you the freedom from swelling and induration, the absence of inflammatory reaction and fever, and the comfort of these patients as compared with those who

were treated by the antiseptic methods that were in vogue the year before. One of my most vivid recollections is of a young soldier who had sustained a penetrating wound of the knee joint with fracture of both tibia and femur. The surgeon had laid the joint widely open by an incision extending upward along the medial side of the upper part of the leg, transversely across the patellar tendon, and upward along the lateral side of the lower part of the thigh. The loose bone fragments had been removed, the shell fragment and the clothing and skin carried in before it carefully and completely removed from the lower end of the femur, the joint cavity irrigated with salt solution, and the entire wound closed in layers and without drainage. In the days of my internship at the Cook County Hospital only three years before, such treatment would have been heresy, yet eight days after operation in a casualty clearing station this boy lay with the lower extremity immobilized in a Thomas splint, with normal temperature, with the operative wound healed, and with only a slight swelling of the suprapatellar bursa as evidence of wound reaction. That was only one of many such cases, but it stands out in my memory with peculiar vividness. It seems little short of tragic that the hard won and costly lessons of the World War should be so often ignored and forgotten in our teaching of surgery today.

ILLUSTRATIVE CASES

Here are a few illustrations of recent cases from the service of Dr. Michael Mason and myself at Passavant Memorial Hospital.

CASE 1—A man, aged 35, tripped over a rug April 29, 1934, and as he fell thrust his left hand through the glass of a French window toward which he was walking. He sustained a deep transverse wound just above the wrist, with immediate and profuse bleeding. A doctor in the room immediately applied compression above the wound and shortly afterward a sterile dressing and pressure bandage over the wound. When I saw the patient ninety minutes later he could move all his fingers well but had a complete loss of sensation in the area of median nerve distribution and loss of the ability to rotate his thumb so that it faced the fingers.

The patient was anesthetized immediately, and the hand and forearm and finally the wound itself cleansed very gently but thoroughly with soap and water. Examination of the wound showed, in addition to complete division of the median nerve, division of the tendons of the palmaris longus and the superficial flexor to the middle finger, and partial division of the tendons of the superficial flexors to the ring and little fingers, the flexor pollicis longus and the flexor carpi ulnaris. The injured tendons were repaired and finally the median nerve accurately reunited with very fine silk sutures. The wound in the skin and subcutaneous tissue was accurately closed without drainage and a light splint applied to maintain immobilization and volar flexion at the wrist.

The wound healed by primary union and the patient was dismissed from the hospital with the hand splinted in volar flexion at the wrist on the third day after operation. Four months later he was moving his fingers normally and there were definite signs of returning function of the muscles supplied by the median nerve and of returning sensation in the area of median nerve distribution.

CASE 2—A boy, aged 6 years, sustained a deep transverse cut of his left palm as he fell headlong over an ash pile Nov. 30, 1935. It was not determined whether the injury was caused by sharp tin or broken glass. The wound bled profusely until a first aid dressing and tourniquet were applied by a physician who saw him twenty minutes after the injury. The patient was admitted to Passavant Memorial Hospital in the service of Dr. Michael Mason ninety minutes after the injury. Examination of the hand without removal of the dressing showed

motionless fingers and anesthesia of the entire palmar surface of hand and fingers.

The patient was immediately anesthetized, and the forearm hand and finally the wound itself carefully washed with soap and water. To make certain that cleansing was as complete as possible the edges of the wound, which extended in a curved line almost completely across the proximal portion of the palm, were held apart with sterile retractors so as to expose its entire depth. The soap solution was washed away with sterile water and the divided structures (fig. 1)—nine tendons and four nerves, for the ulnar nerve was divided 1 inch distal to its division into its two digital branches and its deep muscular branch—were united by end-to-end suture. Finally the subcutaneous tissue and skin were accurately united. The wound healed by primary union.

Feb. 21, 1936, twelve weeks after the injury, the boy was beginning to use his fingers (fig. 2) and there were definite signs of returning sensation over the proximal portion of the palm.

CASE 3—A girl, aged 8 years, sustained a crushing injury of the distal phalanx of the left ring finger as it was caught by a closing door June 2, 1935. The distal half of the distal phalanx was almost avulsed but still held by a flap of skin and soft tissue on its radial side. The bone had been completely fractured and the distal portion torn away with the soft tissues which surrounded it.

The patient was seen forty-five minutes after the injury. The finger tip was dusky and cyanotic but it seemed possible that one digital vessel had escaped injury. The patient was anesthetized immediately with nitrous oxide, the hand and wound were cleansed with soap and water and the distal bone fragment brought back into place as accurately as possible. The "cap" of soft tissue was fitted over it and the skin edges united as exactly as possible with fine horsehair sutures. No sutures were placed on the dorsal surface so as to avoid injury of the nail bed.

A pressure dressing was applied so as to prevent passive congestion of the flap. The wound healed by primary union.

CASE 4—A mechanic, aged 38, sustained multiple lacerated wounds of three fingers when his left hand was caught in an electric fan June 11, 1934. The most serious injuries consisted of a laceration of the dorsal surface of the index finger at the proximal interphalangeal joint with division of the extensor tendon and joint capsule, and the loss of two half square inches of skin over the middle phalanx of the index and the distal phalanx of the middle fingers. The dirty wounds were carefully cleansed by Dr. Michael Mason, the joint capsule and the divided extensor tendon were accurately united, the lacerations were united with fine sutures and two small grafts were laid over the denuded areas. The wounds and grafts healed without infection.

CASE 5—A mechanic, aged 46, sustained burns of both hands April 18, 1935, from blazing gasoline. Linseed oil and gauze dressings were applied shortly afterward at a nearby hospital. He was admitted to Passavant Memorial Hospital an hour after the injury. The oily material and greasy dirt were washed from his hands as he soaked them for nearly a half hour in two large basins of sterile water and soap suds. When the hands were clean they were allowed to dry under a heat lamp and then sprayed with 5 per cent freshly made tannic acid solution. The hands were alternately sprayed and dried during a period of twelve hours, when tanning was almost complete. Some exudation of serum from the right hand continued for almost three days. The day after admission the patient's temperature was 101.4 F and there was considerable swelling and redness of the right forearm just proximal to the burned area. These symptoms gradually subsided, the patient was dismissed from the hospital seven days after admission with the dry crusts covered with a light protective dressing and the right hand immobilized in a light splint. Separation of the crusts was complete eight days later.

CASE 6—A workman, aged 40, was admitted to Passavant Memorial Hospital March 29, 1934, shortly after he had sustained a crushing injury of the left hand. While repairing a freight elevator he was suddenly carried upward clinging with his upstretched hands to the floor of the elevator. His left hand was caught between the floor of the elevator and the upper beam of the doorway just as the elevator was brought

to a stop. The soft tissues over the dorsum of the metacarpus were crushed and torn away. The skin over the dorsal surfaces of the proximal phalanges of the index, middle and ring fingers was white, bloodless and insensitve (fig 3). Over the metacarpus a part of the extensor indicis proprius had been avulsed, the surface of the common extensor tendons to the index and middle fingers was ragged and torn, but the tendons were not divided.

After the hand and forearm had been shaved and cleansed with soap and water the wounds themselves were carefully cleansed. The crushed and lacerated edges of skin about the wound on the metacarpus were cut away, leaving a denuded area involving the greater part of the dorsum of the hand. The free ends of the partially destroyed extensor indicis proprius were sutured to the adjacent tendon of the common extensor. A free full thickness graft of skin of the exact size and shape of the defect was then dissected free from the abdominal wall and sutured accurately in place over the defect. A second similar graft was used to fill the defect in the dorsum of the ring finger. On the middle and index fingers it was possible to approximate the skin edges, after excision of the devitalized skin and subcutaneous tissue.

When the pressure dressing was removed and the wounded areas examined for the first time eight days after operation it was seen that a small area of dry necrosis approximately one inch square, had developed where the large graft lay over bare extensor tendons. Elsewhere the grafts had healed perfectly. This necrotic portion of the graft was cut away a few days later, and the patient left the hospital three weeks after the injury. When healthy granulation tissue had formed over the raw spot, thirty-seven days after the injury and primary operation a thin graft was laid over the granulations and healing was complete a week later. Figure 3 shows the hand immediately after the injury, and figure 4 two years after the injury.

CASE 7—A woman, aged 34, was admitted to Passavant Memorial Hospital in the service of Dr. Michael Mason April 23, 1935, shortly after she had sustained multiple serious injuries in an automobile accident. The most severe injuries consisted of a comminuted supracondylar fracture of the left humerus, lacerations of the left parietal and right orbital regions, and a deep abraded wound of the dorsum of the right hand with tangential loss of a portion of all the metacarpal bones and complete loss of all the tissues—tendons, nerves, blood vessels and covering tissues—overlying them (fig 5).

The extensive wound of the hand was carefully cleansed with soap and water and debrided and the lacerations of the head and face cleansed and sutured, but because of shock and, later, the difficulty of securing complete reduction and satisfactory immobilization of the fractured left humerus, six days elapsed before it was possible to raise a flap from the right thigh and lay the hand underneath it. In the meantime the hand had been dressed daily with every care to avoid adding infection to the large open wound. May 29, just one month after the hand had been placed under the flap, its attachments were divided, suture of the cut edges to the hand completed, and the raw surface left on the thigh covered with thin grafts.

Figure 5 shows the hand immediately after the injury and as it lay underneath the flap, and figure 6, eleven weeks after the injury. Dr. Mason plans at a later date to transplant tendons underneath the flap to replace the destroyed extensor tendons.

SUMMARY

The arrest of hemorrhage, the treatment of shock, and the careful examination of the hand—not the wound, are the first steps in the care of an injured hand. The principles involved in the further treatment, as in the treatment of any compound injury, are care not to add injury to that which has already taken place, careful excision of hopelessly injured tissue, the use of a minimum amount of foreign material in the repair of the injured structures, closure of the open wound as soon as it can be done with safety, and rest until healing has taken place.

Special Article

THE CHOICE OF ANALGESICS

R. W. WAGGONER, M.D.

ANN ARBOR, MICH.

This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—ED.

It has been said that, "next to the saving of life, the relief of pain is a physician's most important function." Most patients can be made relatively comfortable in order to prevent the use of energy in the form of actual physical and nervous response to painful stimuli. Protection from these stimuli will allow the use of this energy for a better purpose. On the other hand, the indiscriminate and illogical use of analgesics is frequently unsatisfactory and may actually cause more damage than the pain itself. The type of analgesic should be chosen with care from an analysis of the patient's condition. Pain is an important factor from the diagnostic point of view, but once the type of pain, its situation, frequency and duration are noted it becomes unnecessary and the patient has every right to expect relief. Pain having served its purpose as a warning should be eradicated as soon as possible. The means by which pain is to be relieved depends largely on the type of pain and the causative factors. For rational therapy, therefore, the physician must analyze the situation and proceed accordingly.

Obviously, the causative factor must be removed if and when possible. For example, an inflamed appendix should be removed, tabetic patients with root pain should receive the proper sort of antisyphilitic therapy. Headaches associated with some organic manifestation should be treated accordingly. In the meantime, however, it is the duty of the physician to control the symptoms which the patient manifests until such time as the removal of the cause is possible. Analgesics that are satisfactory for the control of one type of pain may be almost valueless in another case. In order to decide the type of analgesic to be used, it will be of value to develop some sort of classification of the different types of pain.¹

PSYCHALGIA

In such a classification psychalgia, or pain without organic cause, should be considered first. It would seem that all pain, whether secondary to some physical pathologic process or associated with no chemical or physical cause, must have a psychologic component, the degree of psychologic component present varying with the patient as well as with the disease. There is apt to be a greater degree of fear and consequently a greater degree of psychologic pain in certain types of conditions than in others, and the diminution of fear or anxiety whether by psychotherapy or by physical means will very distinctly assist in the control of physical pain. Certain types of pain, particularly if there happens to be a large element of psychalgia, will respond poorly even to large doses of morphine. On the other hand, a small

The author is indebted to Mr. Harvey Whitney, chief pharmacist of the University Hospital for assistance in preparing the prescriptions used in this paper.

¹ Dunlap H. A. *Lancet* 2:909 (Oct. 19) 1935.

dose of some one of the barbiturates, together with a relatively small dose of morphine, may result in complete relief of the patient's symptoms. It is possible to relieve even the most severe types of pain in given individuals by strong suggestive therapy without the use of any of the chemical analgesics. The proper amount of psychotherapy correctly used, irrespective of the type of chemical analgesia necessary, is always of value and should never be neglected. Care should be used in the diagnosis and treatment of psychalgia, since if it is

PRESCRIPTION 1—Sodium Bromide and Ammonium Valerate

| | | |
|---|---|-----------------|
| R | Sodium bromide | 100 Gm |
| | Elixir of Ammonium Valerate | to make 600 cc. |
| M | Label One teaspoonful, diluted with water three times daily after meals | |

PRESCRIPTION 2—Carbromal

| | | |
|---|---|-------|
| R | Carbromal | 50 Gm |
| | Divide into 15 capsules (or tablets) | |
| L | Label One capsule after meals and two before retiring | |

PRESCRIPTION 3—Phenobarbital

| | | |
|---|---|--------|
| R | Elixir of Phenobarbital | 600 cc |
| | Label From one teaspoonful to one tablespoonful before bedtime (Each teaspoonful contains 0.016 Gm) | |

handled badly the patient's attention may be fixed on some symptom and increase rather than diminish the manifestations. If one is sure that there is no organic component in such a situation, one should be exceedingly careful in the use of any physical or chemical therapy.

THE NEURALGIAS

The neuralgias present a serious problem from the point of view of treatment. Under the general term must be included, of course, certain treatment-resistant conditions such as tic douloureux, atypical neuralgia

PRESCRIPTION 4—Aminopyrine

| | | |
|---|--|-------|
| R | Aminopyrine | 50 Gm |
| | Divide into 15 capsules (or tablets) | |
| L | Label One capsule every three hours as required to relieve pain. | |

PRESCRIPTION 5—Acetylsalicylic Acid

| | | |
|---|---|-------|
| R | Acetylsalicylic acid | 50 Gm |
| | Divide into 15 capsules | |
| L | Label from two to three tablets every three hours as required | |

PRESCRIPTION 6—Aminopyrine

| | | |
|---|---|--------|
| R | Elixir of Aminopyrine N F | 600 cc |
| | Label From one to two teaspoonfuls (each teaspoonful contains 0.16 Gm of Aminopyrine) | |

of the face, intercostal neuralgia, post-herpetic neuralgia and sciatic neuralgia. In the treatment of these, perhaps mechanical therapy or surgical intervention is in the end the most satisfactory. However, in the meantime the patient should be kept comfortable and in cases that are not too severe perhaps proper mechanical therapy combined with judicious analgesic medication may eliminate the necessity of surgical intervention. In such circumstances it must be remembered that because of the chronicity of these conditions morphine and its derivatives are contraindicated. Aminopyrine

and salicylic acid derivatives are in general most satisfactory for the treatment of these cases.

Of the special neuralgias, trichloroethylene has been suggested in the treatment of tic douloureux but at best should be used only as a temporary type of treatment. It is usually somewhat unsatisfactory. Even

PRESCRIPTION 7—Trichloroethylene

| | | |
|---|------------------------|--------|
| R | Trichloroethylene | 100 cc |
| | Divide into 10 ampules | |
| L | Label Inhale vapors | |

morphine may fail in handling this particular type of condition and should not be used unless the patient is under the continuous observation of the physician.

NEURITIS

In contrast to the neuralgias, patients with neuritis show definite neurologic changes, such as sensory changes, changes in the reflexes and muscle weakness etc. Since a great many of these cases are associated with toxic conditions of some sort, care must be exercised not to prescribe any medication that will increase the toxic manifestation. In cases of neuritis, as in cases of neuralgia, mechanical therapy is of great value. As a necessary adjunct, however, one should include the use of proper analgesics. The pain in most of these cases will yield fairly promptly to the use of amino pyrine or the salicylates, but early in the treatment of the condition the pain may be so severe as to necessitate the use of morphine or one of its derivatives.

ROOT PAINS

Three important conditions come under the heading of root pains: tabes dorsalis, spinal cord tumor and radiculitis. In the first two, obviously, the important consideration is to treat the underlying condition. In spinal cord tumor, for example, removal of the tumor, if operable, will usually result in prompt relief of the pain. In the other two, however, the patient must be made comfortable by the use of analgesia, particularly during the period of treatment. During this time

PRESCRIPTION 8—Analgesic for Radiculitis

| | | |
|---|--|---------|
| R | Acetylsalicylic acid | 35 Gm |
| | Acetophenetidin | 25 Gm |
| | Caffeine | 0.5 Gm |
| | Codeine sulfate | 0.25 Gm |
| M | Divide into 15 capsules | |
| L | Label One or two capsules at onset of pain. May repeat in an hour. | |

various types of analgesia may be used. A patient with tabes dorsalis whose pain is very severe, whether associated with the characteristic root pains involving the extremities or associated with a gastric crisis, should be made quiet and should be relieved of fear of repeated attacks of pain. The use of one of the longer acting barbiturates is often of great value in such cases. Ordinary analgesics such as aminopyrine, acetylsalicylic acid and acetophenetidin will rarely have much effect but may be tried on such cases. Obviously, because of the frequent recurrence of attacks of such pain, morphine and its derivatives are contraindicated. A successful method of handling these cases is to administer intravenously one of the intravenous barbiturates, giving the patient enough medication to make him semiconscious and keeping him in such a condition for a period of from twelve to twenty-four hours, when the patient is allowed to regain consciousness the

attack may be gone. This procedure should be used with great caution, and not as a general practice. This type of treatment is to be used only in conjunction with the antisyphilitic therapy which should be instituted as soon as the condition is recognized. In the treatment of radiculitis, on the other hand, the milder types of analgesia oftentimes serve quite satisfactorily. One may try aminopyrine, acetophenetidin or a salicylate

PRESCRIPTION 9—*For Pain in Spinal Cord Tumor*

| | |
|--|----------|
| R Morphine sulfate | 0.15 Gm |
| Physiologic solution of sodium chloride | 10.00 cc |
| M Make a sterile solution | |
| Label Give 1 cc. hypodermically as ordered (1 cc. equals one fourth grain) | |

In the spinal cord tumor cases, the pain may be controlled with morphine or some of its derivatives until such time as the patient comes to operation.

HEADACHE OR CEPHALALGIA

One of the most common conditions to which man is heir is headache. Since it may be due to a multitude of causes, it is obvious that different types of analgesia should be used according to the type of condition present. It is likewise obvious that, if the causative factor can be found, this should be removed. For example, in allergic conditions the patient should eliminate the reacting substance, or, in brain tumor, the tumor, if operable, should be removed. In meningitis the inflammatory lesion deserves immediate consideration from the standpoint of treatment. Local disorder in the nose or throat, visual disturbances, such as refractive error, should all be treated as such. Fre-

PRESCRIPTION 10—*Acetylsalicylic Acid Combined with Acetophenetidin and Caffeine*

| | |
|--|--------|
| R Acetylsalicylic acid | 3.5 Gm |
| Acetophenetidin | 2.5 Gm |
| Caffeine | 0.5 Gm |
| M Divide into 15 capsules | |
| Label One or two capsules at onset of pain. May repeat in an hour. | |

PRESCRIPTION 11—*Ergotamine Tartrate*

| | |
|---|----------|
| R Ergotamine tartrate | 0.015 Gm |
| Divide into 15 tablets | |
| Label One to two tablets at the onset of an attack. | |

PRESCRIPTION 12—*Acetylsalicylic Acid with Acetanilid and Hyoscyamus*

| | |
|---|---------|
| R Acetylsalicylic acid | 5.0 Gm |
| Acetanilid | 1.5 Gm |
| Extract of Hyoscyamus | 0.15 Gm |
| Divide into 15 capsules | |
| Label One capsule every two to four hours as needed for pain. | |

quently evening or nocturnal headaches are associated with syphilis and in such cases active antisyphilitic therapy should be administered.

As a type of palliative medication the analgesic must be chosen according to the cause of the headache, if it is to be most effective. So-called reflex headache and headache associated with anxiety, excitement or depression may be controlled with relatively small doses of acetylsalicylic acid, the acetylsalicylic acid may be combined with other analgesics and caffeine. These drugs, on the other hand, have little influence on the patient with migraine or allergic headache. In ordinary migraine, most attacks can be controlled relatively easily

by one or two hypodermic injections of ergotamine tartrate, or the ergotamine tartrate may be taken by mouth.

The use of ergotamine tartrate is not without some danger of ergotism. In some of these cases moderate doses of analgesic medication together with large enough doses of a barbiturate to induce sleep may result in complete relief of the symptoms.

Headaches that are associated with gastro-intestinal upsets and toxic factors of various sorts, as after acute alcoholism, respond very well to acetanilid prescriptions. In the use of this drug, however, one must guard against habit formation and poisoning.

MISCELLANEOUS CONDITIONS

In patients who have increased muscular tone associated with cramping of the muscles and constant severe pain, one chooses the analgesic according to the condition present. For example, in patients with paralysis agitans, scopolamine hydrobromide administered three times daily over a relatively long period occasionally gives relief. During the attacks of pain the scopolamine effect can be boosted by the use of aminopyrine or if necessary an occasional hypodermic of morphine or one of its derivatives. On the other hand, muscle cramps as seen in athletes, which cause very severe pain, may be promptly relieved by the use of aminopyrine or acetphenetidin.

In thalamic disease the patient occasionally complains of very severe and almost intractable spontaneous pain. Obviously, no operative procedure is possible under such circumstances. These cases, although rare, are perhaps the most difficult to treat, frequently requiring large doses of morphine. Occasionally one gets better results by the use of morphine sulfate combined with one of the lesser analgesics such as aminopyrine or acetphenetidin.

The pain associated with dysmenorrhea presents a very important problem and one frequently encountered. In those cases in which there is some cause which can be corrected, this should be done rather than

PRESCRIPTION 13—*Acetylsalicylic Acid Combined with Amytal*

| | |
|-------------------------------------|---------|
| R Acetylsalicylic acid | 5.0 Gm |
| Amytal | 0.75 Gm |
| M Divide into 15 capsules | |
| Label One capsule every three hours | |

continuing the use of analgesics from month to month. However, in such cases it may be necessary to use some type of analgesia and in such cases the physician should attempt to estimate the degree of pain and use a drug that produces the desired degree of analgesia. Frequently these situations are a mixture of emotional disturbance and actual pain, and as a result a drug combination of an analgesic together with a sedative is of more value than a single analgesic drug. The use of acetylsalicylic acid or acetophenetidin combined with some mild sedative such as phenobarbital or amytal is usually quite satisfactory. Possibly the combination of aminopyrine and the barbiturates should be frowned on. The amount of the analgesic drug can be increased according to the severity of the pain. The sedative medication, however, should be about the same in most cases. In some instances the pain may be severe enough to require one of the opium derivatives.

In the control of pain associated with trauma, one should not hesitate to use the opium derivatives in most cases unless one expects the cause of the pain to last for a relatively long period. Some qualification of this

may be considered in the treatment, for example, of fractures, in which the introduction of a local anesthetic such as procaine into the fracture site may very markedly reduce the pain associated with reduction of

PRESCRIPTION 14—*Neocinchophen*

Label One capsule every three hours

the fracture and obviate the necessity for general anesthesia. The end results are said to be better than in those cases in which general anesthesia is used.

One of the most satisfactory drugs in the treatment of the pain associated with the degenerative types of arthritis, such as hypertrophic arthritis, is cinchophen or neocinchophen. Since neocinchophen gives such excellent results and is less toxic, it should be used rather than cinchophen.

In chronic infectious arthritis the pain is relieved more satisfactorily by the use of salicylates.

SUMMARY

Much has been written during the past few years concerning the harmful effects of certain drugs. Perhaps aminopyrine has been most severely indicted for its supposed cause of agranulocytosis. There are still many who are afraid to prescribe this splendid analgesic because of the possibility of harm resulting from its use.² The property of producing agranulocytosis may be due to the benzene ring, but many cases of industrial benzene poisoning have been noted without agranulocytosis.³ It is logical to believe that there may be an idiosyncrasy to the drug,⁴ just as there is to many other valuable drugs. It should not be discarded because of the unfortunate reaction in a few cases.

Similar criticism of the use of cinchophen and neocinchophen has been raised because this drug is presumed to cause liver damage. Studies on experimental animals have not proved that these drugs have a constant specific liver toxic effect even when given in doses far in excess of the therapeutic dose.⁵ An analysis of the literature would indicate that these drugs may be prescribed safely when a proper indication for their use exists.

Many of the barbituric acid derivatives have been used for the relief of pain. The high comparative dosage of these drugs necessary for analgesic action makes their routine use for such purposes inadvisable.

Sensitization to acetylsalicylic acid is said to be frequent among allergic persons.⁶ Placing a small bit of the drug on the tongue and allowing it to dissolve will produce itching, cough or asthma in a short time in sensitized persons.

The physician should recognize first of all the temperament and personality of his patient and, secondly, the situation, type and severity of the pain, and he should prescribe his analgesic medication accordingly. If the patient is a high strung, so-called nervous individual and there appear to be many emotional components in the situation, obviously much greater benefit will be derived from the use of some sedative medication in conjunction with the analgesic to be prescribed. On the other hand, a plethoric, nonemotional individual who has severe pain may be given an analgesic without the sedative component. It should be remembered in the use of this type of medication that habit formation is easily established and in those cases in which the pain is apt to be present over a long period drugs should be used which are least likely to induce habit formation. The narcotics, therefore, should be used rarely and only in emergency situations, not in those cases in which analgesic medication may be necessary over a long period.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

BECK-LEE SHORT WAVE DIATHERMY MACHINE ACCEPTABLE

Manufacturer Beck-Lee Corporation, Chicago

The Beck-Lee Short Wave Diathermy is designed for medical and surgical diathermy. It is a two-tube machine having a modified circuit of the push-pull type. No condenser is used in the tank circuit, the capacity between the turns of the coils being utilized. The wavelength is between 15 and 16 meters. The input power required to operate the unit is approximately 750 watts. Since there is no acceptable method of measuring the output power of short wave machines, this value is not given.

Fig 1—Beck-Lee Short Wave Diathermy

Fig 2—Schematic diagram of circuit

The shipping weight of the unit is approximately 50 pounds. Both pad and cuff electrodes are furnished as standard equipment.

In accordance with the regular procedure of considering devices submitted to the Council the firm was asked to present evidence to substantiate the claims made for the device. Tissue heating effects in the human thigh were observed. Cuff electrodes were applied to the thigh, one posterior to the hip and the other anterior to the knee. Thermocouples were introduced into the deep-lying tissues and also into the subcutaneous tissues being placed midway between the electrodes and temperature readings were made immediately before and after the treatments during which the thermocouples were removed. After twenty minutes' treatment, the machine being operated at the

patient's tolerance the temperature rise and final temperature (average of six tests) were observed to be comparable to those temperatures obtained when using conventional diathermy as a control.

The machine was used in a clinic acceptable to the Council and the foregoing report was confirmed. The temperature rise of the transformer was found to come within the limits accepted by the Council. The unit was operated under actual conditions for a period of three months. It gave satisfactory service both for medical and for surgical diathermy. Burns may be produced by this or any other short wave machine, but they may be avoided by ordinary precautions.

In view of the favorable report on the unit, based on its performance when cuff electrodes were used the Council on Physical Therapy voted to include the Beck-Lee Short Wave Diathermy in its list of accepted apparatus.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

INJECTION TREATMENT OF HERNIA

In March 1936 the Council on Pharmacy and Chemistry of the American Medical Association addressed a questionnaire to a selected list of hospitals, with a view to obtaining data on the injection treatment of hernia. This method is now being exploited actively to the medical profession by many purveyors of mixtures of one type or another, used in this method of treatment. In the questionnaire, information was sought particularly as to the extent of this practice, its safety and its effectiveness, the extent of unfavorable complications, and the nature of such complications.

Replies, which were received from most of the institutions addressed, indicated that the method is not used in the majority of the hospitals consulted and that it is considered safe and effective by those using it, although many qualified their opinion as to safety and effectiveness by specifying careful selection of cases. Several unfavorable complications were recorded, including mild infections, the development of fibrous masses of cutaneous tissue, and failure of the method to correct the hernia. In addition, there were some instances of painful scarring, occasional cases of swelling of the testis, and a few instances of subsequent impotence. In two cases, gangrene followed the use of the method.

The solutions used by various observers included sodium morrhuate, a mixture of phenol, alcohol and oil of thuja, and several mixtures containing tannic acid or tannic acid derivatives. In some of the institutions, preparations of proprietary character, such as the Pina-Mestre solution, Galtanol and Proliferol, were used.

Opinions varied as to the number of cases suitable to this method of treatment. In those most favorable, from 12 to 15 per cent of cases were treated by the injection method. Other institutions reported that the majority of cases of hernia in the outpatient clinic were treated by this method.

Several reports concerned surgical operations on patients who had been formerly treated by the injection method ineffectively. The surgeons report, however, that the previous injections had not made later surgery more difficult.

One of the complications involved in the introduction of the method has been the attitude of the insurance organizations, workmen's compensation boards and similar groups, in relation to bearing the cost of such a procedure. Another complication has been the fact that the method has been taken up by osteopaths and even by laymen, and that some of the difficulties that have arisen are due to the results of such nonmedical use of the injection method.

In some institutions in which physicians especially well trained have been put in charge of the injection method as administered in the outpatient clinic the results seem to be quite satisfactory not only to the special worker but also to

the members of the surgical staff who have followed these cases. The most unfavorable opinion seems to be that there may be more recurrences attending the injection of the indirect inguinal hernia than follow under adequate operative care.

It must be borne in mind, however, that these are ambulatory patients and that this type of care permits continued industrial employment as well as releasing a considerable number of beds for patients definitely requiring surgery.

Subsequent to the issuance of the questionnaire by the Council on Pharmacy and Chemistry, a letter was addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION by some fifty physicians in good standing who have been using the injection method citing their opposition to some of the criticisms contained in the questionnaire and emphasizing the fact that suitable selection of cases, injection by experienced practitioners, and suitable control of the patients treated make the injection method just as safe as, if not safer than a surgical procedure. These fifty physicians are convinced that the injection method is applicable and effective in the majority of cases of hernia, that it is often applicable when surgery is inadvisable and vice versa, and that it is just as free from complications and dangers as are surgical procedures. It is their opinion that the method will develop greater usefulness as it is more definitely understood, as the solutions used are more capably investigated and standardized, and as the limitations and uses of the method are more completely worked out.

With this point of view the Council on Pharmacy and Chemistry is inclined to agree. Nevertheless, the following considerations should be borne in mind not only by those expert in the injection method but also by the medical profession in general. The attempted cure of hernia by the application of the method of adhesive inflammation is not new. The method has, however, failed to establish itself as a routine method for the treatment of hernia and is still in an early experimental stage. In view of these facts, surgeons who practice this method should realize the dangers from an ethical, a legal and a financial point of view.

Those who inject into the bodies of their patients mixtures of unknown composition, not suitably standardized by any unprejudiced agency, and capable of bringing about definite pathologic changes in living, healthful tissue, may be subjecting themselves to unwarranted risk of legal difficulties should unfortunate results ensue. Those who continue to experiment with the injection method for the treatment of hernia with a view to standardizing this method will do well to use only such mixtures as may be prepared under their own direction in the laboratory of the hospital with which they may be associated, or mixtures prepared by competent pharmacists according to prescriptions prepared by the physician himself.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

DEXTROSE (See New and Nonofficial Remedies, 1935, p 280 and THE JOURNAL, June 27, 1936, p 2239)
Hospital Liquids, Inc., Chicago

The several accepted dextrose solutions (in distilled water and in physiologic solution of sodium chloride) marketed in Filtrair Containers of 1 000 cc. capacity are also supplied in 500 cc. containers.

POLLEN EXTRACTS-MULFORD (See New and Nonofficial Remedies, 1936, p 41)

The following additional products have been accepted

Grass Mixture Pollen Extract Mulford (Timothy, June, Orchard Sweet Vernal and Red Top Grass Pollen in equal proportion), Grass Mixture Pollen Extract Mulford (Pollens of Southwestern Grasses Bermuda Grass and Johnson Grass 30 per cent each June Grass and Timothy Grass 20 per cent each)

These products are marketed in vial and syringe treatment packages containing graduated doses, representing respectively 5, 10, 20, 40, 60, 100, 200, 400, 700, 1,000, 1,500, 2,000, 3,000, 4,000, 5,000, 6,000, 7,000, 8,000, 9,000 and 10,000 pollen units. Also in packages of three 5 cc vials containing respectively 100, 2,000 and 20,000 pollen units per cubic centimeter.

SATURDAY, SEPTEMBER 26, 1936

ARE WE GROWING BIGGER?

The grown children of today entering colleges and universities in the United States seem to average two inches taller and weigh some seven pounds more than did their parents and grandparents who entered the same schools. A similar observation has recently been made abroad. Measurements of the rate of growth of children in recent years have been accurately made in a number of German cities.¹ All agree in showing considerable increases in height and weight during the last few years. Thus the mean height of boys entering school between 6 and 6½ years of age in 1924 was 108.7 cm, in 1932 it was 114.9. Over the same period the mean of girls increased from 108 to 114.5 cm. Similar changes in weight were noted. The mean height of boys leaving school at about 14 years of age increased from 146.4 cm in 1924 to 152.7 cm in 1933. The mean weight of the boys changed from 38.9 Kg to 42.7 Kg during the same period. Similar changes occurred in girls. In seeking an explanation it must be remembered that some of the children either were born in the period of war or postwar privation or as infants suffered from severe dietary deficiencies during the same period. Additional information, however, is available. Thus the average height of recruits in Norway increased 3.01 cm between the years 1878-1887 and 1923-1925, in Holland 6.67 cm between the years 1863-1867 and 1921-1925, in Sweden 4.5 cm between the years 1846-1850 and 1921-1922, in Switzerland 9.5 cm between the years 1792-1799 and 1861-1872, in Denmark 3.69 cm between the years 1852-1856 and 1904-1905, and in Italy 2.1 cm between the years 1855-1859 and 1896.

These figures appear to confirm those reported by Bowles² in this country in 1932. The latter investigations were based on the anthropometric measurements of fathers and sons at Harvard University and mothers and daughters who attended Vassar, Wellesley, Smith

and Mount Holyoke colleges. The available material from Harvard included a small series of 481 couples (400 fathers and their sons) for whom thirty measurements and seven observations were available, and a large series for which only heights, weights and nationalities were available, numbering 1,461 couples (1,160 fathers and their sons). The statistical accuracy of the information obtained was open to some question from the standpoint of the small numbers involved, but the variants were such that comparisons of reasonable accuracy could be drawn. Racially the material of the Harvard study was remarkably constant, only 5.79 per cent containing other than "old American" stock. Of this small proportion 3.9 per cent were of purely British stock—much the same as the original "old American". The results with regard to stature could be summarized as follows: 1. Sons are absolutely taller than their fathers. 2. In the student population for at least the past eighty years and probably longer there has been a marked annual increase. The rate has varied, reaching a peak in those born between 1860 and 1870, when the mean annual increase was 0.15, and dropping in those born between 1905 and 1910, when the increase was 0.07. 3. The mean annual rate of increase for the entire student population for the past eighty years has been approximately 1 cm every twelve and one-half years, statistical significance occurring every eight and one-half years. 4. For the population as a whole the figure is somewhat smaller but is probably between 0.06 and 0.07 cm per annum. 5. The mean stature of the present-day "old American" student population in Massachusetts and vicinity is 178.03 cm, rating thus among the tallest people observed anywhere and 4 cm or more above the population as a whole. 6. There is no significant correlation between age and stature among students between the usual college ages of 17 and 23. 7. The increase in one generation, approximately thirty-five years, has been 3.55 cm, or about 1¼ inches. The weight studies could be summarized as follows: 1. Male students as a whole have shown a mean annual increase of 2¼/100 pounds during the past fifty years. 3. Weight increase has been to a certain extent associated with stature increase in that the greatest increases were noted in the same decade, but the falling off of increment has been more marked for weight. 4. Proportionally weight has not increased at the same rate as stature, consequently, significant difference occurs every eleven and one-half years as opposed to every eight and one-half in stature. 5. Men are today getting taller and slenderer even though in absolute weight they exceed their parents. For the college women studied the mean increase in stature of the daughters over their mothers was 2.93 cm. The mean weight of the daughters was 4 pounds over that of the mothers in the group studied.

A number of other measurement comparisons were reported by Bowles which should serve for a background in extending the studies of gradual physical

¹ Are We Growing Bigger? Brit. M. J. 1, 1163 (June 6) 1936.

² Bowles G. T. New Types of Old Americans at Harvard Cambridge Mass. Harvard University Press 1932.

evolution. The causes for the increase in weight and stature remain uncertain. At present he lists the most probable as increased medical attention in preserving those children who have outgrown their strength until they have reached maturity and a normal state of resistance to disease, cultural modernization and a general speeding of processes, better food in more abundance and in greater variety, more exercise, possible assortive and selective mating on the part of parents, occupational change of parents, and nonascertainable elements of climatological and meteorological effect.

ECZEMA FROM DYED CLOTHING

Dermatologists for many years considered eczema a dermatosis caused by endogenous metabolic disturbances, and some still accept this doctrine. Repeated efforts to obtain accurate proof for this view have yielded uniformly negative results. True, the production of eczema by the injection or ingestion of iodine, quinine or arsphenamine, for example, indicates that products of metabolism may in certain special instances play a part in the etiology of the eczematous condition. However, quantitative determinations of various constituents of the urine and of the blood of eczematous persons have resulted in a complete failure to relate any endogenous metabolic disorder to the many types of eczema. From the standpoint of physiologic chemistry, therefore, eczema is not a metabolic disease. This makes fallacious the numerous dietary measures that have been suggested for treating the condition. Evidence has rapidly accumulated, however, which indicates conclusively that external factors play a far more important part than was formerly assigned to them in the etiology of acute, subacute and chronic eczema. In considering the etiology of eczema, due regard must be given to the not infrequent significance of the individual constitutional factor or human idiosyncrasies. Hypersensitivity to the primrose or to *Ascaris* are classic examples of idiosyncrasy. The thorough work of Bloch¹ has aided greatly in distributing the proper emphasis among the possible etiologic factors in eczema and has developed the somewhat newer, allergic, view of the condition.

Of the environmental factors that are the most common causative agents of eczema, articles of clothing are of considerable significance. Numerous illustrative references are contained in the literature and serve to demonstrate the difficulty in diagnosis of the cause in each patient. Generalizations are extremely difficult because of individual susceptibilities, and each case usually requires prolonged observation and study, but the results obtained are generally well worth the extra time and effort required to secure them. These points are strikingly illustrated in an interesting report by

Simon and Rackemann.² Small eczematous areas and lesions developed from time to time in a man in widely diverse portions of the body and at varying intervals over a period of from four to five years. Various local applications had no apparent effect on the course of the disease, and roentgen therapy resulted in only temporary improvement. Repeated microscopic examinations and cultures failed to reveal fungi, a general physical examination gave no evidence of focal infection. Sensitization was considered, but skin tests by the scratch method with extracts of all foods in the patient's diet and with many epidermal products and pollens all gave negative results. A careful consideration of the location of the lesions, and the fact that lesions on the ankles disappeared when white socks were substituted for colored ones worn previously suggested clothing as a cause of the eczema. Proof was soon obtained by patch tests that a wide variety of articles of colored clothing were responsible for the long suffering from localized areas of eczema. The most important and interesting of these eczematous recurrences were lesions in the neck from the collar of an overcoat, on the forehead from the hat band, on the legs from the garters, on the feet and ankles from socks and shoes, on the feet, legs, hands, arms, face and neck from bed clothing on the hands from automobile upholstery, and on the hand and forearms from the varnish on a mahogany table, the linings of two suits, his wife's dresses, and the upholstery of living room furniture. Lesions on the face, eyelids and genitals were shown to result from transference of the allergen by the fingers. On one occasion the eyelids were so swollen that the eyes could not be opened. By exercising great care in avoiding contacts, the recurrences of severe eczema have been avoided. In further interesting experiments with this subject, the Boston investigators demonstrated that the reaction produced was dependent on the dyestuff and not on a combination of the coloring substance with protein or some other constituent of the fabric. Various classes of dyes were tested, all the azo dyes gave positive tests in this subject, whereas all other types of dyes were negative with the exception of three triphenylmethane dyes, which were weakly positive. Studies designed to determine which portion of the dyestuff molecule was responsible for the specific eczematous reactions threw suspicion on the diazo linkage, diazoaminobenzene gave a strongly positive test on the patient. It should be pointed out that all these positive tests were obtained by the patch method, uniformly negative results were obtained when the scratch method of testing was used. This serves to illustrate the importance of the patch test in diagnosis and treatment and as a means of preventing contact with new clothing and other materials likely to cause trouble.

¹ Bloch, Bruno. The Role of Idiosyncrasy and Allergy in Dermatology. *Arch. Dermat. & Syph.* 19: 178 (Feb.) 1929.

² Simon, F. A. and Rackemann, F. M. Contact Eczema Due to Clothing. *J. A. M. A.* 102: 127 (Jan. 13) 1934.

Recently an illuminating report³ of fifteen cases of eczema due to dyed clothing has served to emphasize the difficulties in making an accurate diagnosis of the condition, the careful study required in each case, and the frequency with which the condition may be encountered. All the cases reported from the Danish clinic were traced directly to dyes present in articles of clothing, in many cases a positive eczematous reaction was observed when the patient was tested with dyes of relatively simple chemical structure. Aromatic amines were particularly effective in producing the reaction. It is interesting to note that several patients showed reactions to tests with substances of an entirely different chemical nature. These observations would seem to suggest that patients who have eczema from dyed clothing may have an idiosyncrasy and are particularly easy to sensitize. A study of the individual cases serves to illustrate the importance of obtaining a thorough history in order to determine the origin of the eczema in each instance. Furthermore, the observation of this rather considerable number of cases within a relatively short period adds significance to the importance of dyed clothing as an etiologic factor in eczema.

Current Comment

SEYDEL ARTHRITIS TREATMENT —THE AFTERMATH

The tempest created by the premature publicity for the proprietary product promoted by Seydel through the American Chemical Society session in Pittsburgh has subsided, leaving behind it a calm atmosphere indicating that much good was accomplished by the protest which THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION made against the publicity methods. The paper of Seydel was read in a closed meeting of the American Chemical Society. Dr. Paul Nicholas Leech, Director of the Bureau of Foods, Drugs and Physical Therapy of the American Medical Association, took part in the discussion. Following this discussion a statement was issued by Dr. Edward Bartow, president of the American Chemical Society, Dr. Thomas Midgley, chairman of the board of directors, and Dr. Norris Shreve, chairman of the division of medicinal chemistry, jointly with Dr. Leech. This statement said:

In the discussion it was pointed out that much more work is necessary before the product can be considered as of established value. Representatives of the American Chemical Society and the American Medical Association agreed that the difficulties which have ensued in the past will be eliminated in the future by closer cooperation.

In the future, publicity released by the American Chemical Society as it affects the recommendation of drugs and medicinal products will be suitably controlled. The American Medical Association has no desire to assume responsibility for the subjects to be discussed before other organizations. It is, however,

definitely the province of the American Medical Association to see that medicine is not misrepresented by the use of the good auspices of any organization to undermine the confidence of patients in the medical profession or to promote the sale of new products of unestablished clinical value. THE JOURNAL commends the stand taken by the American Chemical Society in the control of its future publicity and readily offers its facilities to reputable organizations that seek information on topics definitely within the medical field.

REMOVING ADHESIVE TAPE

The deaths of two football players at Purdue University and the serious burning of several others as a result of the explosion of gasoline focuses attention on the correct method of removing adhesive tape. From time to time, various recommendations have been made as to the easiest methods of performing this task. Every one knows that it is painful to turn up one edge of the adhesive tape and to jerk it suddenly away from the skin. Furthermore, this will pull out the hair—and even remove the skin—and give opportunity for secondary infection. Gasoline has been recommended in the past, as well as ether and various volatile oils. Kerosene has also been employed for removal of adhesive tape from the skin. None of these substances meet the optimal indications. For some time ethyl acetate was advocated, but it has a definite fire hazard and is irritating to the eyes, nose and throat. Carbon tetrachloride is known as a standard fire extinguisher. It is not inflammable and is frequently used for the removal of tape. It constitutes the chief ingredient of some of the well known cleaning fluids on the market. Recently the Council on Pharmacy and Chemistry has voted to accept¹ two solvent preparations proposed primarily for the removal of adhesive tape from the skin. One² of these substances consists of 98 per cent dichloromethane and has no fire hazard, since it is non-explosive and noninflammable. However, it is similar to chloroform in its action and the same precautions are necessary as to its inhalation. The other product³ is a mixture of approximately 60 per cent carbon tetrachloride and 40 per cent naphtha with a small amount of oil of sassafras. Such a mixture may burn but will not explode under ordinary conditions and in the ordinary sense is considered to be noninflammable. With any of these preparations there may be some danger associated with the removing of large quantities of tape in small rooms without proper ventilation. This is, however, a minor danger and should not be seriously disturbing. Certainly it is a far less hazard than the use of gasoline anywhere near a source of flame or heat. Coaches and trainers of football teams will do well to equip training quarters with plenty of modern improved solvents so as to eliminate the danger of catastrophe such as that which has thrown a somber atmosphere about the current football season.

1 Acceptance awaits receipt of properly revised advertising and labels to conform to the Council's decision.

2 Dichloromethane Solvent Belle marketed by Belle Alkali Company, Charleston, W. Va.

3 Ohio Carbon Tetrachloride Compound marketed by Ohio Chemical and Manufacturing Company, Cleveland.

Medical Economics

MICHIGAN FILTER SYSTEM

The Michigan State Medical Society has undertaken to integrate all its activities so as to assure cooperation and prevent overlapping. One phase of the society's work has become of special importance in relation to the operation of two state laws. These laws provide for free medical care for "afflicted children" and for "crippled children." The first is an exclusive state affair, the second is conducted in cooperation with the Federal Social Security Act, which provides about \$100,000 annually as a subsidy from the federal government.

If financial and medical resources are to be used effectively and economically, two preliminary examinations are necessary before any assistance is given. The Michigan State Medical Society has assisted in the organization of two "filters" to be used in the selection of those who are to receive medical care. This system has been organized by the Public Relations Committee of the Michigan State Medical Society and seventeen district counselors.

Dr L. Fernald Foster of Bay City, chairman of the Public Relations Committee, explains the operation of this system as follows:

- A The County Medical Society appoints in each county of the state
 - 1 A Medical Filter—a board of physicians who shall decide on each applicant as to
 - (a) medical need
 - (b) medical necessity and urgency
 - (c) necessary period of hospitalization and treatment

- B The judge of probate appoints with advice and counsel of the county medical society's representatives
 - 1 An Economic Filter—a social servicing agency which shall determine
 - (a) whether the patient can pay the existing fee of the private physician
 - (b) whether the parent is temporarily unemployed or a worker in the low wage bracket who can pay the fee of the private physician on a deferred payment plan
 - (c) whether the parent is one who cannot now or apparently at any future time pay anything to his private physician

An applicant under the Afflicted and Crippled Child Act should be referred first to the economic filter. If he is judged to fall in the economic group he is worthy of consideration by the medical filter to which he should next be referred. If his condition is medically needy or urgent, his commitment by the judge of probate should follow. All other cases rejected by either filter should return as private patients to the physicians of their choice for disposition.

The economic filter is appointed by the probate judge of each county and is composed of laymen. Most of the counties of Michigan have a three man board composed of the county poor commissioner, superintendent of the poor and perhaps a state welfare agent or the probate judge. In some of the larger counties the regular social service investigation bureau is used. The medical filter is composed of physicians appointed by the county medical society.

After one county medical society in the state had operated this form of filter on "afflicted adults" (the responsibility of the counties, not the state) sufficiently long for its value to be shown, a joint committee of representatives of the Michigan State Medical Society, Michigan Hospital Association, the Michigan Association of Probate Judges, the State Administrative Board, the Crippled Children Commission and the Auditor General's Office met Oct. 30, 1935, in the office of the Auditor General and adopted a resolution endorsing the "filter" system for crippled and afflicted children, and providing for the two committees described. On June 4, 1936, Governor Frank D. Fitzgerald issued an executive order providing:

IT IS ORDERED that no state money shall be paid for the care and treatment of afflicted or crippled children until there has been filed with the Judge of Probate a statement by a parent or legal guardian under oath and approved by the Economic Committee giving fully the economic condition of the parents or guardians of said children including the details of property owned and income received by all members of the family and such other information as such Economic Committee requires—and until there shall have been a physical examination by said Medical Committee of said Filter Board with a report thereof in plain terms, filed with the Judge of Probate. If the Judge of Probate makes an order for the medical and/or surgical treatment, bills rendered to the state therefor shall be accompanied by certified copies from the Judge of Probate of the county of both the Economic Committee report and the Medical Committee report.

This plan is now in operation in eighty-two counties in the state of Michigan. Michigan would appear to have worked out outlines of an experiment that may prove of great value in the organization of medical service. It is the first state to establish a state-wide method of selection on both economic and medical grounds and to separate these so as to give both the lay and professional representatives as complete autonomy as is possible with close cooperation. It is an experiment which may well be studied with interest and profit by medical associations throughout the country.

Association News

GRANTS FOR RESEARCH

The Committee on Scientific Research of the American Medical Association invites applications for grants of money to aid in research on problems bearing more or less directly on clinical medicine. Preference is given to requests for moderate amounts to meet specific needs. For application forms and further information, please address the Committee at 535 North Dearborn Street, Chicago.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

The Poliomyelitis Situation—A total of 346 cases of infantile paralysis with twenty-five deaths was reported between January 1 and September 18, showing an increase of eleven cases over an earlier total of 335 reported in *THE JOURNAL*, September 19. Jefferson County still leads in incidence with seventy-two cases, while Lauderdale County is second with forty-eight, Morgan County, thirty-nine, Colbert, twenty-eight, Franklin, twenty-one, and Cullman, eighteen.

ARKANSAS

Personal—Dr. Melvin E. McCaskill, Little Rock, was recently appointed to the state board of health to succeed the late Dr. Wells F. Smith, Little Rock.—Dr. Roy E. Schirmer, formerly of Little Rock, has been named director of the Mississippi County health unit at Blytheville, succeeding Dr. Arthur M. Washburn.

Society News—A joint meeting of the Southeast Arkansas Medical Society and the Fourth Council District Medical Society was addressed at Monticello, August 17, by Drs. Virgil L. Payne, Pine Bluff, on "Ionization Treatment of Hay Fever," Alan G. Cazort, Little Rock, "Desensitization Method of Treating Hay Fever," and John S. Wilson, Monticello, "Report of Four Cases of Cholecystitis with Cholecystectomy in Children."

COLORADO

Health at Denver—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 12, indicate that the highest mortality rate (17.2) appears for Denver and for the group of cities as a whole, 9.7. The mortality rate for Denver for the corresponding period last year was 13.7 and for the group of cities, 9.7. The annual rate for eighty-six cities for the thirty-seven weeks of 1936 was 12.3 as against a rate of 11.5 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

State Medical Election—Dr. William T. H. Baker, Pueblo, was chosen president-elect of the Colorado State Medical Society at the annual meeting September 12 and Dr. Arthur J. Markley, Denver, was installed as president. Dr. Albert C.

McClanahan, Delta, was elected vice president. The next annual session of the society will be at the Antlers Hotel, Colorado Springs, late in September 1937. Dr. Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, was elected to honorary membership in the society at the recent meeting. New by-laws were adopted and the house of delegates gave its approval to the proposed revision of the constitution, with the recommendation that it be adopted without change at the next annual session. Under a new plan the board of trustees, composed of nine members, includes the president, president-elect, vice president, constitutional secretary, treasurer, and four additional trustees. With this arrangement it will be impossible for more than four members of the board of trustees to go off the board any one year, and as a rule only three will do so.

CONNECTICUT

University News—Yale University, New Haven, will receive \$50,000 to erect an addition to the university infirmary and \$50,000 for its maintenance, in accordance with the will of the late Mrs. Grace Witbeck Barrell, Chicago. An endowment of \$75,000 is also established for the university, the income to be used to assist three deserving students a year. This endowment is created in memory of Mrs. Barrell's son, John, a former student at Yale, who was drowned in 1916, aged 25.

New Regulations for Wells in New Haven.—The proposed location of a well, the type of construction and the uses to which the water is to be put will henceforth be under the supervision of the New Haven Department of Health in accordance with a recently adopted regulation, effective August 15. The regulation provides that, on completion of the construction of any well so registered, a final report as to the depth and size of the well, pumping facilities and other pertinent information shall be furnished to the department of health within ten days after completion.

IDAHO

State Medical Meeting and Election—Dr. Arthur C. Jones, Boise, was chosen president-elect of the Idaho State Medical Association at its annual meeting, September 4, and Dr. Dailey C. Raj, Pocatello, was installed as president. The program consisted of a series of lectures by six members of the faculty of the University of California School of Medicine, San Francisco, forming a course of graduate instruction with no papers by members of the association. The speakers were Drs. Curle Latimer Callander, on abdominal surgery, amputation and gas gangrene, Langley Porter, pediatric subjects, Howard E. Ruggles, x-ray diagnosis, Gordon E. Hein, diseases of the intestinal tract, infections of the chest, pneumoconiosis and postoperative complications, George K. Rhodes, surgery of the large bowel, abdominal injuries in relation to industry and treatment of infections, and Chauncey D. Leake, Ph.D., pharmacologic subjects. At a meeting to which the public was invited, the speakers were Drs. Porter, on "The Physician's Place in the Community", Leake, "Medicine in Art", Ruggles, "The Process of Digestion as Revealed by the X-Rays", and Hein, "Diet". The annual banquet was held Tuesday evening, September 1, with Ralph H. Lutz, Ph.D., professor of history at Stanford University, as the speaker, on "The European Crisis of 1936".

ILLINOIS

The Prevalence of Syphilis—Totals of 150,462 cases of syphilis and 176,094 of gonorrhea were reported in Illinois during the ten years ended with 1935, according to the state department of health. During the same period 1,232,746 births were recorded, indicating that about one in every eight or nine children is destined to be infected with syphilis at some time during life unless the sources of infection are cleared up. In 1935 a total of 15,628 cases was reported against 12,577 in 1926, with 12,988 and 19,813 as minimum and maximum figures for intermediate years, the department stated.

Society News—At a meeting of the Adams County Medical Society in Quincy, September 14, Drs. Richard S. Weiss and Duff S. Allen, St. Louis, discussed drug eruptions and recent developments in surgery of the thyroid, respectively. Dr. Rosco G. Leland, Chicago, addressed the Sangamon County Medical Society in Springfield, September 3, on "The Economics and Ethics of Medicine."—Dr. Margarete M. H. Kunde, Chicago, addressed the Iroquois County Medical Society in Watseka, September 24, on endocrine therapy.—Dr. Henry Schmutz, Chicago, addressed the Kankakee County Medical

Society in Kankakee, September 10, on carcinoma of the cervix.—Dr. Raymond W. McNealy, Chicago, discussed cancer of the breast before the Peoria City Medical Society, September 15.

CHICAGO

Gift to Promote Instruction in Psychiatry—The Rockefeller Foundation has granted to the University of Illinois College of Medicine a fund of \$15,000 a year for three years to promote undergraduate instruction in psychiatry. The work is under the immediate supervision of Dr. Harold Douglas Singer, professor and head of the department of psychiatry, and was begun September 1. In general, the program involves the extension of psychiatric teaching into other departments of medicine, particularly that of internal medicine.

Addition to Surgical Institute for Children—A three-story addition to the Surgical Institute for Children, University of Illinois College of Medicine, is now under construction. The basement will contain an all tile hydrotherapy pool. On the first floor there will be a solarium which will accommodate twenty patients at one time for ultraviolet treatments, and a gymnasium and apparatus room completely equipped for corrective exercises. Occupational therapy, recreation, case and general duty rooms will occupy the second floor, while the third will be given over to a complete laboratory, including fume and dark rooms, and two large school rooms with adjustable desks for the children. The present building is undergoing minor alterations on various floors which will increase its capacity about sixty beds, making a total of 144 beds to be occupied by indigent crippled children from all parts of the state.

IOWA

Stream Pollution—According to the state department of health, of the 330 municipalities having sewerage systems 237 have sewage treatment plants. Only three of sixteen first class cities in the state have sewage treatment plants, while 233 out of 314, or 74 per cent, of the smaller cities and towns have treatment plants.

Ophthalmology and Otolaryngology Meeting—At the annual meeting of the Iowa Academy of Ophthalmology and Otolaryngology in Marshalltown, September 16, the program included the following:

- Dr. Rollin W. Wood, Newton, Salivary Calculi
- Dr. Warren H. Foster, Clinton, Peritonsillar Abscess
- Dr. Edward C. Nowak, New Hampton, Uveitis Caused by Focal Infection
- Dr. Thomas R. Gittins, Sioux City, Acute Conditions in the Chest from the Bronchoscopic Standpoint

The program opened with the presentation of cases and concluded with a symposium on malignant conditions of the ear, orbit, nose and throat, presented by Drs. Placidus J. Leinfelder, Iowa City, Howard E. Thompson, Dubuque, and Dean M. Lierle, Iowa City.

KANSAS

Medical Exhibit at Jubilee Celebration—The Sedgwick County Medical Society will sponsor an exhibit depicting the advancement of medical science, at the Kansas diamond jubilee exposition in Wichita, October 7-17.

Society News—The Wyandotte County Medical Society was addressed, September 1, by Drs. Harry W. King and Henry L. Regier, Kansas City, on "Malignancy of the Colon" and "Emergency Care Following Accidents" respectively.—The Kansas City Rotary Club dedicated its meeting, August 11, to the medical profession, speakers were Drs. Harry R. Wahl, medical education, John F. Hassig, medical ethics, Clifford C. Nesselrode, medical organizations and their functions, Thomas J. Sims, our medical law, William J. Feehan, basic science law, and Clifford J. Mullen, socialized medicine.

KENTUCKY

Personal—Dr. Jesse M. Dishman, Greensburg, health officer of Green County has been appointed health officer of Caldwell County to succeed Dr. B. Kirtley Amos, resigned.—Dr. Ernest L. Gates, Greenville, has been appointed a member of the state board of health.

Society News—Dr. Murray L. Rich, Covington, addressed the Grant County Medical Society, Williamstown, August 19, on pernicious anemia.—The Jefferson and Fayette county medical societies held a joint meeting in Louisville, September 21, with Drs. Fred W. Rankin and Ernest B. Bradley, Lexington, as speakers, on "The Evolution of Surgery of the Colon and Rectum" and "A Medical Glance at the Past Thirty Years" respectively.—Dr. Frank W. Pirkey addressed the

Louisville Eye and Ear Society, September 10 on "Sympathetic Optic Neuritis"—At a joint meeting of the medical societies of Graves and Fulton counties in Mayfield, August 26, speakers were Drs Henry G Reynolds, Paducah, on diseases of the ear, Edward B Houston, Murray, diseases of the heart, and Earle C Walter, Mayfield, cancer of the uterus

MASSACHUSETTS

Personal—Drs W Russell and Andrew R MacAusland have been appointed clinical professors of orthopedic surgery at Tufts College Medical School, Boston

Memorial Presented to Academy—A series of six panels done in oil by Miss Harriet Ellis depicting the doctor from 1636 to 1936 was presented to the Springfield Academy of Medicine at its first meeting of the year, September 15. The panels are a memorial to a group of twenty-seven colleagues who served Springfield during their lifetime in a particularly distinguished manner, according to the *New England Journal of Medicine*. Dr George L Schardt, chairman of the medical profession's committee for the observance of the tercentenary of Springfield, read a paper entitled "Rewards of Service." The academy was addressed, September 22, by Dr Vilray P Blair, St Louis, on "Injuries of the Bones and Soft Tissues of the Face"

MICHIGAN

Dr McCord Heads Bureau of Industrial Hygiene—The Detroit Department of Health recently established a bureau of industrial hygiene and occupational disease to cooperate with industry in the elimination of work conditions inimical to workers health. It will be advisory and educative rather than a regulatory or law enforcing agency. In addition to field investigations, laboratory studies have been instituted seeking methods for the control of industrial intoxications. The department is in charge of Dr Carey P McCord as director, William H Carey Jr as sanitary engineer, W G Frederick as chief chemist, and Herbert Walworth as engineer for field activities. Dr McCord, formerly of Cincinnati, recently directed the establishment of the industrial hygiene laboratories of the Chrysler Corporation, Detroit

MISSOURI

Personal—Dr Lynn M Garner, director of the Miller County Health Department, Tuscumbia, has been appointed to a similar position with the Greene County Health Department, succeeding Dr John W Williams Jr, who will become associated with the state department of health

Dedication of New Auditorium—The entire third floor of the Receiving Building, Kansas City General Hospital, has been set aside for the use of the Jackson County Medical Society. The meeting of the society, September 15, was devoted to the dedication of the new auditorium, with Dr Albert Graeme Mitchell, B K Rachford professor of pediatrics University of Cincinnati College of Medicine, Cincinnati, giving the dedicatory address. His subject was "What Now Physician?" Other speakers were Dr Edwin H Schorer director of health of Kansas City, and Judge Henry F McElroy, city manager. Dr Frank R. Teachenor, president of the society presided at the meeting, which was the first in the new quarters

NEW YORK

Society News—The annual joint meeting of the Syracuse Academy of Medicine with the Utica Academy of Medicine was held at the Syracuse Yacht and Country Club, September 17. In the afternoon there was a golf tournament followed by a clambake. In the evening Drs Arthur R Grant and Thomas Wood Clarke, Utica, addressed the meeting on "Venoclysis—Uses and Abuses" and "Little Recognized Types of Allergy" respectively. Dr Gabriel Tucker, Philadelphia, addressed the Medical Society of the County of Westchester, at Grasslands Hospital Valhalla, September 15, on bronchoscopy in relation to general practice

New York City

Cornell to Cooperate in City Health Center—Cornell University has donated to the city a site on East Sixty-Ninth Street between First and York streets near the medical school for a health center which will be used jointly by the city for health promotion work and by the school for training of medical students. It is reported

Personal—Dr Fred H Albee on a recent trip to South America was made an honorary member of medical organizations in Brazil, Peru, Chile, Argentina and Ecuador, he was elected honorary president of the Brazilian Society of Ortho-

pedic Surgery and Traumatology and appointed a member of the faculty of medicine and surgery of the University of Chile.—Dr Stanley L Wang read a paper on quartz light therapy at the Third International Congress for Study of Light held in Wiesbaden, Germany, September 1-7

William Hallock Park Laboratory to Be Dedicated—The new public health laboratory of the New York City Department of Health, named in honor of Dr William Hallock Park, founder and director emeritus of the laboratory, will be dedicated October 6. Speakers at the ceremony will be Drs Thomas Parran Jr, surgeon general U S Public Health Service, Charles Gordon Heyd, Vice President American Medical Association, George W McCoy, director National Institute of Health, Washington D C, Augustus B Wadsworth, director, state laboratory, Albany, Anna W Williams for many years assistant to Dr Park, Charles-Edward Amory Winslow, Dr PH, New Haven Conn, and Mayor La Guardia

Lectures on Dental Medicine—Mount Sinai Hospital announces a course of lectures on dental medicine for the coming year. Following are the speakers and subjects

Dr Charles K Friedberg October 8 What Part Does Dental Infection Play in Systemic Disease?
Dr Isidore Friesner November 12 Dental Infection and Its Relation to Otiology
Dr Abraham Hyman December 10 Focal Infection and Its Relation to Urologic Diseases
Dr Joseph Harkavy January 14 Allergy in Relationship to the Teeth and Gums
Dr Ira Cohen February 11 Trigeminal Neuralgia Diagnosis and Treatment
Dr Robert K Lippmann March 11 Relationship of Arthritis to Focal Infection
Dr Isidore Goldstein April 8 Dental Infection and Its Relationship to Diseases of the Eye

Medical Exhibits for the 1939 Fair—Plans for the health and medical exhibits at the New York World's Fair of 1939 have been announced by Grover Whalen, president of the fair corporation. Louis I Dublin, Ph D is chairman of a committee to arrange the exhibits, Dr James R Reuling Jr Bayside, N Y, vice chairman, and Homer N Calver, former secretary of the American Public Health Association, secretary. Other members of the committee are Drs Victor G Heiser, George Baehr, John L Rice and Sigismund S Goldwater. The major objectives of the committee are a coordinated health and medical exhibit to be the nucleus of a permanent museum of health and hygiene, a model health village, educational work through protective devices and services for visitors throughout the fair, provision for a permanent health center, and censorship of medical and other products sold or promoted on a health basis

Symposium on Dysentery—The department of medicine, New York Postgraduate Medical School and Hospital, offers a symposium on dysentery, September 26, concluding a course on gastro enterology which it has sponsored during September. The symposium is planned to include two general divisions, dysentery as a public health problem and practical clinical aspects of dysentery. Discussing the first division will be Dr Samuel Frant, epidemiologist, state department of health, Dr Hollis S Ingraham district state health officer of New York, Dr George W McCoy, director National Institute of Health Washington, D C, and Lewis V Carpenter, associate professor of sanitary engineering, College of Engineering of New York University. Dr John L Rice, city health commissioner, is chairman. With Dr Walter G Lough, executive officer of the department of medicine, as chairman, speakers treating the second division will be Drs Ralph S Muckenfuss, acting director, bureau of laboratories, city department of health, Francis W O'Connor, associate professor of medicine Columbia University College of Physicians and Surgeons, and Ward J MacNeal, professor of pathology and bacteriology. Zacharias Bercovitz, instructor in medicine, Adolph G G DeSanctis, professor of clinical pediatrics and Rupert Franklin Carter, associate professor of surgery, all of New York Post-Graduate Medical School of Columbia University

OHIO

Society News—The Summit County Medical Society held a joint meeting with the Akron Bar Association in Akron September 8 with Dr Walter G Stern, Cleveland and William L Hart LL D, lecturer of international law and political science, Mount Union College Alliance, as speakers on "The Lawyer in Court and The Doctor in Court" respectively.—Drs Ludwig F Derfus and La Verne C Ziegler Salem will address the Columbiana County Medical Society, East Palestine October 13 on "Undulant Fever and 'Common

Colds" respectively — Dr Chester D Christie, Cleveland, addressed the Geauga County Medical Society, Chardon, July 29, on glands of internal secretion

OREGON

State Medical Meeting at The Dalles—The sixty-second annual meeting of the Oregon State Medical Society will be held at The Dalles October 8-10. The guest speakers on the program will be

Dr Clifford D Sweet, Oakland Calif The Child as a Patient
Diagnosis and Treatment of Upper Respiratory Tract Infections in Children
Acute Surgical Conditions of the Abdomen in Children
Dr Claude E Dolman Vancouver B C Diagnosis and Treatment of Localized Staphylococcal Infections
Diagnosis and Treatment of Generalized Staphylococcal Infections Principles and Practice of Serum Therapy
Joseph T Tamura Ph.D., Cincinnati Cultivation of and Immunological and Clinical Studies with Lymphogranuloma Inguinale

Dr Olin West, Chicago, Secretary and General Manager of the American Medical Association, will make the principal address at the annual banquet. The following Oregon physicians, all of Portland, are listed on the preliminary program:

Dr Otis F Akin Treatment of Fractures of the Neck of the Femur
Dr Richard F Berg Pathology of the Knee Joint
Dr Edmund H Berger Kidney Function in Alkalosis
Dr James Marr Bissailon Pneumonia
Dr Harry C Blair Common Disorders of the Feet
Dr Isidor C Brill Treatment of Auricular Fibrillation
Dr Louis P Gambee Infections of the Hand
Dr Franklin P Johnson A New Ureteral Stone Snare
Dr George N Pease Surgical Anesthesia
Dr William M Wilson Etiology Pathology and Treatment of Functional Uterine Bleeding
Dr Francis B Zener A More Effective Method of Treatment of Trichomonas Vaginalis Infection in Women

PENNSYLVANIA

Society News—Dr William Wayne Babcock, Philadelphia, addressed the Lawrence County Medical Society, September 23. —Dr Francis M Pugliese, Wilkes-Barre, addressed the Northampton County Medical Society, September 18, on "Management of Obstructive Jaundice."

State Medical Meeting at Pittsburgh—The eighty-sixth annual meeting of the Medical Society of the State of Pennsylvania will be held in Pittsburgh October 5-8 at the Hotel William Penn. General sessions will be held in the mornings and section meetings in the afternoons. Guest speakers will be

Dr William S McCann Rochester N Y Sclerosis—Determination of Disability with Reference to Workmen's Compensation
Dr Sumner L S Koch Chicago Infections of the Hand
Dr Elliott P Joslin Boston Diabetes (in symposium)
Dr Leslie N Gay Baltimore Treatment of Asthma Based on Etiologic Factors
Dr George W Crile Cleveland Genesis and Surgical Treatment of Essential Hypertension
Dr Frederic W Baneroff New York Inguinal Hernia
Dr Henry P Wagener Rochester Minn Clinical Interpretation of Vascular Lesions in the Retina in Hypertensive Disease
Dr Albert C Furstenberg Ann Arbor Mich Acute Infections of the Mouth Pharynx and Cervical Region
Dr Roy Graham Hoskins Boston Present Status of Endocrinology in Its Relation to the Child
Dr Harold N Cole, Cleveland Venereal Disease, with Particular Reference to Granuloma Inguinale and Lymphogranuloma Inguinale
Dr Gershom J Thompson Rochester Minn Prostatic Resection

Pittsburgh

Obstetric and Pediatric Institutes—The first of a series of institutes on obstetrics sponsored by the state department of health and the Medical Society of the State of Pennsylvania as a part of the health program of the Social Security Act was held at Magee Hospital, September 16. Drs Howard A. Power, Charles E Ziegler and William Paul Dodds of the University of Pittsburgh School of Medicine delivered the lectures. Similar institutes on pediatrics will be presented by Drs Harold H Finlay, Wilkesburg, Henry T Price and David Hartin Boyd.

SOUTH CAROLINA

Graduate Assembly at Anderson—The second annual clinical assembly presented by the Anderson County Medical Society was held at the Anderson County Hospital, September 8-10. The first day was devoted to lectures on diseases of the kidney by Drs Kenneth M Lynch and Joseph H Cannon, Charleston, and James E. Paulin, Atlanta Ga. Wednesday there was a joint meeting with the South Carolina division of the Southeastern Surgical Congress with the following speakers: Drs Edgar G Ballenger, Atlanta on "Office Treatment in Genito-Urinary Diseases"; Joseph D Guess, Greenville, "Office Practice in Gynecology"; Robert E Abell, Chester, "Office Treatment in Traumatic Surgery"; and Joseph M Feder, Anderson, "Biopsies." Speakers the last day were Drs Joseph

I Waring, Charleston, on infant feeding, Robert W Ball, Columbia, who showed a motion picture on county health work, and Richard M Pollitzer, Greenville, "Pediatric Gleanings." A banquet was held at the John C Calhoun Hotel Wednesday evening with Drs Ballenger and Frank K Boland, Atlanta as speakers on "Early Recognition of Urologic Diseases" and "Liver Abscess" respectively. Dr Edgar A Hines, Seneca, is president of the assembly, Dr Jack D Parker, Greenville, vice president, and Dr Archer L Smethers, Anderson, secretary.

UTAH

State Medical Meeting and Election—Dr Menzies J MacFarlane, Cedar City, was chosen president-elect of the Utah State Medical Association at the annual meeting September 3-6 in Salt Lake City. Dr George N Curtis, Salt Lake City, was elected president to take office immediately because of the resignation of Dr Louis E Viko. Vice presidents elected were Drs Lewis W Oaks, Provo, John G McQuarrie, Richfield, and Dr William T Ward, Salt Lake City. Dr Frank M McHugh, Salt Lake City, was elected secretary. Guest speakers were

Dr John H J Upham, Columbus, Ohio President Elect American Medical Association The Changing Times in Medicine
Dr Hamilton H Tyndale New York Present Knowledge of Anterior Pituitary Gonad Functions Gonadotropic Hormones from Blood and Urine with Clinical Applications
Dr Clifford D Sweet, Oakland Calif Diagnosis and Treatment of Upper Respiratory Infections in Children The Child as a Patient.
Dr Charles M Blumenfeld, Salt Lake City Surgical Anatomy of the Hand
Dr Isidor S Ravdin Philadelphia Terminal Ileitis The 'Bad Risk' Thyroid Patient
Dr Walter C Alvarez Rochester Minn Helpful Hints in the Diagnosis of Gastro-Intestinal Disease Food Sensitiveness
Dr Otto Jason Dixon Kansas City Etiology and Treatment of Osteomyelitis of the Skull Major Complications of Mastoid Disease
Dr Karl A Menninger Topeka Kan Psychiatry in Relation to the General Practice of Medicine Alcohol Addiction as a Psychiatric Syndrome
Dr Leo Eloesser San Francisco Sources and Treatment of Bleeding from the Lungs Cancer of the Lung
Dr Fred H Albee New York Recent Advances in Treatment of Fracture of the Neck of the Femur Resection of Bone Sarcoma with Bone Graft Replacement (motion picture) Treatment of Osteomyelitis and Blood Infections with Bacteriophage
Dr William F Braasch Rochester Minn Recent Advances in Treatment of Urinary Infections

At a public meeting Thursday evening Dr Alvarez spoke on "Popular Fads in Diet" and Dr Menninger on "Various Forms of Disguised Aggressiveness in Children." Dr Alvarez also addressed the Woman's Auxiliary on "Why Some Women Are Nervous."

VIRGINIA

Bureau of Industrial Hygiene—The state department of health established a bureau of industrial hygiene July 1 with Dr William D Tillson, Richmond, in charge. The new bureau, financed by social security funds, will first survey the scope and nature of industrial problems in the state and will make its services available to industries that wish information as to actual hazards to which their employees are exposed.

Society News—The Southside Virginia Medical Association held its quarterly meeting in Burkeville, September 8 with the following speakers: Drs Rudolph C Thomason, Richmond on "Gonorrheal Conjunctivitis"; Prosser Harrison Picot, Richmond, "The Climacteric"; Walter L Nalls, Richmond, "Effect of Irritant Gases on the Lungs"; Marshall P Gordon Jr, Richmond, "Tuberculosis of the Kidneys," and John A Proffitt, Burkeville, "Tuberculosis in the Negro Race."

Personal—Dr Jack B Porterfield, Christiansburg, has been appointed health officer of the peninsula district, to succeed Dr George E Waters, Williamsburg, resigned. Dr Sheldon D Carey, recently at Abingdon, has been named to succeed Dr Porterfield as health officer of Montgomery County. —Dr Arthur H Perkins, since 1928 assistant superintendent of the Waterbury (Conn) Hospital has been appointed medical director of the Norfolk General Hospital, a newly created position.

WASHINGTON

State Medical Election—Dr J Reid Morrison, Bellingham, was named president-elect of the Washington State Medical Association at the annual meeting in Yakima, August 31. September 2. Dr Arthur C Crookall, Seattle, was installed as president and Dr Vernon W Spickard, Seattle, reelected secretary-treasurer. Next year's meeting will be in Seattle.

Personal—Dr Eugene B Potter, associate professor of surgery, University of Michigan Medical School, Ann Arbor, has been appointed chief of a service in general surgery at the Virginia Mason Hospital, Seattle. Dr Joel Baker will continue

as chief of another service in general surgery. Dr Potter graduated from Michigan in 1925 and began his service in the department of surgery at that time. In 1930 he was made assistant professor and in 1934 associate professor.

WISCONSIN

New Officers of State Board—Dr Charles W. Giesen, Superior, was elected president of the Wisconsin State Board of Medical Examiners at a meeting at Madison, September 8. Dr Henry J. Gramling, Milwaukee, was elected secretary.

Dr Cantwell Honored—Dr William H. Cantwell, Shawano, was guest of honor at a reception given by his community, August 30, celebrating his long years of practice. Dr Cantwell was graduated from Rush Medical College, Chicago, in 1887 and has spent his life in Shawano and Shawano County. Two of his sons are physicians, Drs Roger C. and Arthur A. Cantwell, Shawano, and one a veterinarian, W. H. Cantwell, Jr. He has been postmaster and health commissioner of Shawano. The speakers at the celebration included Mayor Harry Meyer, Dr Lyndle W. Peterson, president of the Shawano County Medical Society, Attorney M. J. Wallrich and Circuit Judge Edgar V. Werner. Dr Cantwell is 78 years old.

Public Health Position Open—The state bureau of personnel announces an examination for appointment under the state civil service of a supervisor of public health service at \$300 a month. The duties of the appointee will be to coordinate local public, private and professional agencies with the public health activities of the state board of health with special reference to either gonorrhea or venereal disease prevention. The minimum requirements include training equivalent to that represented by graduation from a medical school of recognized standing, additional training in public health, a license to practice in Wisconsin at least three years' practice of medicine desirable, part in the field of public health, thorough knowledge of modern scientific medicine with special reference to gonorrhea or venereal disease or both, physicians between the ages of 30 and 40 are preferred, continuation of the work after June 30, 1937, is dependent on availability of funds under the social security act. Citizenship in the United States and residence of one year in Wisconsin are required. Application blanks may be obtained from the bureau of personnel, state capitol, Madison. The closing date for filing is September 28.

HAWAII

Society News—Dr Oswald Swinney Lowsley, New York, addressed the medical corps of the army and navy and the Honolulu County Medical Society, September 8, on new developments in renal and prostatic surgery; he also conducted an operative clinic at Queens Hospital, Honolulu, September 10.

GENERAL

Droughts in the United States—According to a recent statement by the U. S. Department of Agriculture, for about sixty years previous to 1930, when the present dry phase began, there had been a number of transitory droughts, and one persistent drought (1886-1895). In the present drought there have been three extremely dry years, 1930, 1934 and 1936. The few available precipitation records covering 100 years or more, indicate that a general dry phase was noted in the thirties of the last century, about 100 years ago. The principal wet phase of the United States climate in the last century was from about 1865 to 1885, with a secondary maximum during the first two decades of the present century, though several transitory droughts were interspersed. Two basic principles are involved in rain production: getting moisture into the air through evaporation and getting it out again through condensation in the form of cloud and rain drops. The only way to produce rain in appreciable amounts is by cooling the air containing the invisible vapor of water. Enough is known of climatic conditions to make ridiculous any suggestion that man can basically change the order of such things.

Accidents Fatal to Children—Twice as many children died in 1930 as a result of accidents as died of measles, scarlet fever and diphtheria, the U. S. Public Health Service reports in a study recently published. Fatal accidents from all causes claimed the lives of 22,044 children under 15 years of age and the three diseases, 10,629. The type of accident changes with age, the investigators found. For infants under 1 year old, mechanical suffocation ranked first for children of 1 and 2, burns caused most deaths. At 3, burns and automobile accidents were about equal. From 4 to 14, automobile accidents held first place; the rate in the group 5-9 years of age was almost twice that for the group 10-14. The statisticians studied

especially the death rate with respect to geographic regions, dividing the United States into four divisions. The rates were: Northeastern, 174 per hundred thousand children; Western, 161; North Central, 148; and Southeastern, 91. Calculated by the number of deaths under 15 years of age per hundred thousand registered automobiles, the percentage changed as follows: Northeastern, 244; Southeastern, 221; North Central, 164; and Western, 135. Another calculation was made of the rate per 50 million gallons of gasoline consumed, giving the following rates: Northeastern, 205; Southeastern, 188; North Central, 158; and Western, 121.

Permit to Enter Canada Required of Certain Physicians—A physician resident in the United States, unless he is a citizen of Canada, cannot lawfully enter Canada for the purpose of working there as an officer or employee of a hospital or other institution unless his entry into that country has first been authorized by the Minister of Immigration and Colonization. Such physicians are, under the laws of Canada, within the scope of the term 'contract laborers.' They therefore cannot enter Canada to work there unless they first show to the satisfaction of the Minister of Immigration and Colonization that their services are required in Canada. A physician desiring to enter Canada for service in a Canadian hospital should make timely application to the Minister of Immigration and Colonization, at Ottawa, submitting evidence that he (1) is a citizen of the United States; (2) is a graduate of a medical school recognized by the licensing authorities in the jurisdiction in which he desires to serve; (3) purposes to proceed to a definite position in Canada, where suitable arrangements have already been made for his care and maintenance during the term of his service; and (4) desires to enter Canada for a temporary stay and not for the purpose of making his permanent home there. The applicant should indicate the place through which he desires to enter Canada and the approximate date of his proposed entry. Application should be filed far enough in advance to make it possible for him to receive some assurance that the evidence that he has submitted has been accepted by the Minister of Immigration and Colonization and to permit the Department of Immigration and Colonization to authorize its officers at the prospective point of entry to permit the applicant to enter. A physician who fails to comply with the requirements of the Canadian laws will be denied entry when he presents himself at any point of entry into Canada. The possibility of such embarrassment should be avoided by obtaining in advance a permit to enter.

Government Services

Centennial Anniversary of Army Medical Library

The one hundredth anniversary of the founding of the Army Medical Library, Washington, D. C., will be observed November 16. The ceremonies will be held in the library building. The library grew from a small collection of books in the office of Surg. Gen. Joseph Lovell in 1836 to 941,181 volumes in 1936. The library owns 450 of the known medical incunabula, numbering about 600 many of them first editions. Of some works, it has the only known copy. Of rare books published after 1500 its collection is one of the best and it possesses 150 early medical manuscripts of great value. The oldest publication it has is Johannes Gerson's *De pollutione nocturna*, printed in Cologne in 1467.

New Head of Pharmacologic Division, Food and Drug Administration

Herbert O. Calvery, Ph.D., senior pharmacologist in the U. S. Food and Drug Administration, has been appointed chief of the division of pharmacology to succeed Dr. Ervin E. Nelson who returns to the University of Michigan October 1 as professor of pharmacology. Dr. Nelson has been on leave from the university since January 1935 for the purpose of organizing the division. Dr. Calvery received his doctorate at the University of Illinois in 1924 and was assistant professor of physiologic chemistry at the University of Louisville and later instructor in physiologic chemistry at Johns Hopkins University School of Medicine. From 1927 until his appointment in the food and drug administration in June 1935 he was assistant professor of physiologic chemistry at the University of Michigan. He has been in charge of biochemical work in the division of pharmacology.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug. 8, 1936

Sir Henry Wellcome

The passing of Sir Henry Wellcome at the age of 82 removes an American who had made his home in this country and was not only a great but a unique figure in the medical world. Born in Wisconsin, he took part as a youth in the great Sioux war in Minnesota, where more than 1,000 white persons were massacred. He studied chemistry and pharmacy in Chicago and Philadelphia. He visited South America and studied the cinchona forests, publishing his observations in scientific journals. He was attracted to London as an ideal manufacturing and distributing center for chemical industries and established there in 1880, in conjunction with the late S. M. Burroughs, the firm of Burroughs, Wellcome & Co., as manufacturers of fine chemicals, alkaloids and pharmaceutical products. The business grew with extraordinary rapidity, and offices and warehouses were established all over the world. For many years Sir Henry Wellcome showed great interest in scientific research to which he became a munificent donor. In 1894 he founded the Wellcome Physiological Research Laboratories. He was a great collector of relics, books and data in connection with primitive customs and ancient methods of medical treatment. He organized the Historical Medical Museum, which was opened in London in 1913 at the time of the International Medical Congress. The most extensive of its kind in the world, it contains exhibits illustrating the development of medicine, chemistry and the allied sciences from primeval times. It has an extensive library of rare manuscripts and printed books. Its purpose is educational and it is of great value to students and research workers. In 1913 Sir Henry Wellcome founded in London the Bureau of Scientific Research to coordinate the work of his separate research institutions as well as to undertake original investigations in tropical medicine, hygiene, sanitation and parasitology. The bureau places its records, equipment and experience gratuitously at the disposal of physicians, sanitary administrators and others interested in tropical medicine and hygiene. Associated with it is the Museum of Medical Science, illustrating for students and other visitors the subjects in a graphic and readily accessible manner. Another research institution associated with the bureau is the Entomological Field Laboratories at Esher, Surrey. In 1931 was founded the Wellcome Research Institution to embrace the various research laboratories and museums founded by him and to provide for their extensive developments. All the laboratories and museums are conducted by a director separately from the business of Burroughs, Wellcome & Co., and although much scientific work is done for the firm, their main activities are original research, which is published in the usual manner. In 1900 he established the Wellcome Tropical Research Laboratories at Khartoum. Here many important investigations into the endemic diseases of tropical Africa have been conducted. In connection with the Association of Military Surgeons of the United States he founded an annual competition for essays on medicomilitary subjects. This list by no means exhausts his benefactions. Many honors were conferred on him—LL.D., D.Sc., F.R.C.S., and last of all F.R.S., which he valued much. His life story might be called a romance of business and science.

Radium Necrosis of the Cornea

At the recent ophthalmologic congress, in London, Mrs. Philippa Martin, F.R.C.S., read a paper showing the danger of applying radium near the eye. She has found that necrosis of the cornea may occur in any case in which intensive irradiation

is used in the treatment of adjacent malignant disease. The time of onset depends on the intensity of irradiation. The reaction is much more severe and early after repeated irradiation or in the presence of sepsis, particularly if intensified by intervention, in the form either of surgery of access or of preliminary operation.

The earliest sign of damage to the cornea is diminution of sensibility. Blinking in response to the touch of light absorbent cotton is slower than in the normal eye. This sign appears within a few weeks of irradiation and may persist for months, but even then normal sensibility may be restored. On the other hand, diminution of the corneal reflex to light touch may be the first indication that radium necrosis will follow.

After a few weeks or months the cornea may lose its polish. As a rule this occurs at the center, but when the irradiation has been from the side the effect may be confined to the corresponding sector. The loss of polish is followed in a few hours by a small superficial ulcer, which spreads slowly. Small areas of ulceration appear in the cornea where the superficial layer has been thrown off. At this stage the condition may be arrested or the areas may coalesce until there is a large superficial ulcer, which may involve the whole cornea except a narrow rim at the periphery. Alternatively the main ulcer may extend by stripping up the epithelium. Within a few days the epithelium splits and the edges of the split are lifted. When the ulcer has been present for some time its edges are undermined for about 5 mm. The base is smooth.

At this stage pain is not marked but it is more severe when there is punctate infiltration, indicating a mild infection. If a mydriatic and bandage are used the eye may remain comfortable and the lesion stationary for months. Under these conditions the eye appears resistant to infection. After some months a few points of yellow exudate may appear in the base of the ulcer, and punctate infiltration, with some deep striation, may also be observed. Infection may also be indicated by a mild iritis which yields readily to treatment. Occasionally perforation occurs, but even then infection of the whole eye is slow to develop. The perforation has been seen to heal, and if this takes place within a reasonable time some sight may be preserved.

Healing will occur provided the reparative powers of the cornea have not been destroyed. Repair may not begin for months and always is slow. When an intensive irradiation near the eye is proposed it is wise to sew the lids together, but in less intense cases strapping is sufficient. As the normal conjunctival reaction to irradiation is chemosis, which may be sufficient to hold the lids apart, closure of the palpebral fissure is the only way to prevent damage to the cornea through exposure. If irrigation of the eye is necessary, physiologic solution of sodium chloride should be used. Zinc lotion especially may give rise to secondary irradiations. During the stage of radium reaction in the skin and conjunctiva, a sensation of pricking and burning is normal, but watch must be kept for pain, which suggests involvement of the iris, either a simple swelling ("iris reaction") or irradiation iritis. In the former, pain is slight in the latter, severe. If the patient complains of pain, a mydriatic should be used and the effect on the pain noted. In all cases of massive irradiation the pupil must be dilated with a mydriatic beforehand and its size noted. After treatment the iris can be examined when the stitch which holds the lids together has been removed. The degree to which the pupil then dilates under the same mydriatic is an index of the presence or absence of an "iris reaction." Probably irradiation iritis is always followed by radium necrosis of the cornea and also by "iris reaction," but in less degree.

Usually an interval of a few weeks occurs before any involvement of the cornea. The first sign is reddening of the eye, probably with some pain. All such cases are worth staining to detect commencing desquamation, as healing may take place

under palliative treatment. If, in spite of this, radium necrosis spreads, tarsorrhaphy must be done. If perforation occurs, the eye can safely be kept for a few weeks to give the perforation a chance of healing.

Provisions for Medical Research

The Medical Research Council has instituted a new scheme of research to encourage young graduates of special ability to undertake research work. Six postgraduate studentships are offered to graduates who have already held house appointments and are strongly inclined to a career in clinical science or experimental pathology. Each student will receive a grant at the rate of \$1,000 a year for a period not exceeding twelve months, for personal maintenance while undertaking approved courses of study such as may be regarded as best calculated to advance his training in methods of research. This may be undertaken under recognized teachers, but it must not include studies to enable him to pass further examinations. The council is also offering four research fellowships for candidates of similar qualifications who have already had experience in research work. Each fellowship will be tenable for one year at the value of \$1,250 and will be renewable in approved instances at the rate of \$1,500 for a second year. These fellowships are intended as probationary appointments for research in clinical science or experimental pathology under suitable direction. Research expenses will be provided in addition to the stipend.

An Experimental Study of Pulmonary Embolism

The experimental production of pulmonary embolism was the subject of a series of communications presented at the May 22 meeting of the Société médicale des hôpitaux of Paris by Villaret, Justin-Besançon, Pardin and Delarue. The object of their research was to determine why a clot in a pulmonary artery can cause death in the majority of cases. The authors maintain that the arterial occlusion and insufficiency of the pulmonary circulation are too frequently cited as explaining the fatal outcome. Clinically, it has been learned that a large artery can be obstructed by a clot, yet death does not occur immediately, as shown by the fact that an operation, as suggested by Trendelenburg, can still be performed to remove the clot. On the other hand, sudden death follows blocking by a relatively small clot and resultant interference of circulation of only a small pulmonary area. During lobectomy or pneumectomy, ligation of a single branch or all the branches of a pulmonary artery is unavoidable, yet no asphyxia results. How does a pulmonary embolism act? Two answers can be given to such a question. (1) Either the embolism acts directly on the respiratory and circulatory functions of the lung or (2) the acute block starts up a series of general phenomena of a reflex character. An extensive study by the authors, presented in 1935 in the *Annales de médecine* showed that both these answers are correct but that each includes only a portion of the real underlying factors. In order to establish major forms of embolism, i. e., blocking of large arteries, the authors employed pearls of enamel (without lead), which were introduced into the external jugular vein of dogs. The pearls varied in diameter from 2 to 8 mm according to the size of the respective vein. Equally good results followed the use of a watery suspension of mucilaginous seeds, which swell and thus block the pulmonary artery. To block smaller arteries, finely powdered pumice stone was used. The experimental results varied according to the size of the foreign body that was employed. Massive obliteration of pulmonary arteries is followed by slight dyspnea or none at all, although a typical triangular infarct ensued. The dog continued to live for several days or even weeks.

Following the introduction of minimal amounts of finely powdered pumice stone, the death of the animal occurred in a few minutes. It was evident that large emboli did not cause death but that the animal died when pulmonary arterioles were blocked. Sudden death therefore is not due to an obstruction of the pulmonary circulation but is the result of a reflex through the action of the embolizing particles acting on the nerve terminations in the arterioles and not of the arteries or capillaries. The neurovegetative modifications can thus play an important part in the anatomic and physiologic changes that follow an embolism.

The histologic changes of hemorrhagic infarction were studied from the instant they took place to their end stage of complete cicatrization of the infarct. The hemorrhagic infiltration of the pulmonary parenchyma is above all the result of a sudden dilatation of the capillaries in a limited area. This is soon accompanied by a considerable thickening (from three to four fold) of the interalveolar septums, an edematous exudate and intra-alveolar hemorrhage. This is the histologic picture in animals killed immediately after the experimental embolism. At the end of fifteen minutes one can already observe foci of infarction. One hour after introduction of the foreign bodies into the jugular vein there is a regression of the congestive phenomena and accentuation of the infarct pictures, which assumes a typical appearance at the end of from twenty-four to forty eight hours, becoming even more so on the seventh, tenth and twentieth days. The lesions begin to show definite regression after the third week, and complete healing (cicatrization) is noted from thirty to ninety days following the experiment.

The authors' theory as to the pathogenesis of pulmonary embolism as revealed by their histologic studies was confirmed by unilateral section of the trunk of the cervical sympathetic, which showed that following such an operation the early pulmonary lesions were quite similar to those observed in post-embolic hemorrhagic infarct at the corresponding period of development.

Also the influence of certain pharmacodynamic preparations on the prevention of death following experimental embolism was studied. Although division of the vagosympathetic trunk is without immediate effect in dogs, division of the vagi in rabbits necessitates an increase in the amount of powdered pumice stone required to produce death from embolism. On the other hand a smaller fatal dose is needed in rabbits if both sympathetic trunks are divided. In dogs to which chloral has been given, although death does not occur after experimental embolism for five minutes, when yohimbine is injected death takes place immediately. On the other hand, when ephedrine was given intravenously death followed only fifteen minutes after the foreign body was introduced into the external jugular vein. This interval was considerably longer after the injection of ephedrine and sodium bicarbonate. Finally when ephedrine atropine and sodium bicarbonate are injected intravenously at the same time, sudden death from experimental embolism does not occur.

These experimental studies serve as a starting point of therapeutic attempts to prevent fatal postembolic accidents.

The Convalescent Serum Center of Strasbourg

At the June 23 meeting of the Académie de médecine, Borrel and Loewenberg reported the results of the center established in 1930 during the severe epidemic of poliomyelitis in Alsace. A stock had been collected of several liters of blood from adult convalescents of former epidemics and from those who had recent infections. In 1931 the collection of serum from measles and scarlatina convalescents was added. Blood from the former (measles) convalescents was obtained from eight to twelve days and from four to five weeks after defervescence for scarlatina. The serum of poliomyelitis convalescents having conserved all its potency since 1930, such donors were asked to return nearly

every month, so that one of these donors has been used forty times. In poliomyelitis, serotherapy when employed during the first four days has been followed in thirty-four cases by 70 per cent of cures. When applied later, 36 per cent of twenty-two cases were cured. In thirty cases of toxic scarlatina the respective convalescent serum yielded twenty-seven cures. Of 180 individuals to whom a convalescent measles serum was given as a prophylactic measure, 160 of the 180 were completely immunized, there were nine mild cases, three showed a doubtful amelioration, and in one case there was complete failure.

Natural Antisyphilitic Healing Forces

Prof Franz Jähnel of the German Institute of Psychiatric Research (Kaiser Wilhelm Institute) in Munich has published in *Forschungen und Fortschritte* a report on recent investigations on natural antisyphilitic healing forces. The favorable effect of pyretotherapy in dementia paralytica is well known, although the complicated mechanism of its action on the spirochetes of syphilis is not yet completely understood. Malariotherapy too is beneficial in early syphilis. Jähnel and Weichbrodt were able to demonstrate with syphilitic rabbits as long ago as 1919 that the first pathologic manifestations and the concomitant spirochetes of syphilis were made to disappear on artificial elevation of the temperature.

Nature is still able in several even more perfected ways to bring syphilitic infection in various animals to a cure. Apes and rabbits in particular, as well as mice, rats and guinea-pigs, are readily infected with syphilis. In the three last named species the infection generally runs its course without the exhibition of any symptoms. Several wild animals are also susceptible to syphilis, the loir (*Myoxus glis*), for example, as Jähnel found. The hibernation of these creatures differs from ordinary sleep not only in profundity but because metabolism is reduced to a minimum and the body temperature, which tends to adapt itself to that of the environment, is drastically lowered. In some animals it was found to be around 5 C. (41 F.), in others it sank to within a few tenths of a degree above 0 C. (32 F.). The loir possesses a singular capacity for heat regulation and thus avoids the death by freezing that otherwise would threaten. As the need arises, increased respiration generates additional heat. Jähnel now reports that syphilitic loirs and hamsters among other animals become healthy again in the course of hibernation. The presence of the causative agents of syphilis could in no way be detected subsequent to the hibernation. Control animals that were kept in a heated room to prevent hibernation could not be rendered free from syphilis within a corresponding period. One might plausibly conclude from this that no actual cure of the disease takes place but rather that the spirochetes undergo a biologic alteration within the hibernating organism and as a result lose their pathogenic properties for other animals. The foregoing hypothesis is, however, as Jähnel made plain, highly improbable, since in many other diseases (trypanosomal infections, for example) complete cure takes place during hibernation. There are, of course, other possibilities. For example, it was found that Alpine marmots which had been infected with bubonic plague during hibernation slept peacefully on without manifesting any pathologic symptoms, but when with the spring they awoke from their winter's sleep the plague erupted among them and killed them all within a brief period.

This natural antisyphilitic curative process is obviously not applicable to man as all mammalia with the exception of the hibernants, are adversely affected by severe refrigeration and besides any appreciable cooling of the human body is difficult to bring about.

Rudolf Virchow, the pathologic anatomist, as is known was able to lower the temperature of his own body only to 35 C. (95 F.) and even in effecting this slight decrease he suffered disturbing manifestations. According to Jähnel's more recent experiments the eradication of the syphilis during hibernation is possible only if body temperature is at least below 20 C. (68 F.). So low a temperature, however, could not be induced in man, the demands of human metabolism alone preclude any such possibility. Moreover, hibernation does not act so forcefully against all species of spirochete. Jähnel found that the spirochete of relapsing fever, for example, could survive a thirty day period of unbroken hibernation. These microorganisms are much less sensitive to external influences than the spirochete of syphilis, they can be preserved in a refrigerator for weeks at a time without undergoing destruction whereas the spirochete of syphilis quickly perishes outside the animal organism itself and even under the most favorable conditions. At present further investigations are under way to determine on what aspect of hibernation the noxious effect on the spirochete of syphilis is dependent. One may find that this phenomenon is due not to the decreased metabolism or body temperature but to an endocrine reaction. The establishment of such a reaction, Jähnel thinks, would help to widen our perspective of the action of syphilis in man as well. In any event, these observations are of fundamental interest.

Deliveries by Midwives

In 1934 there were in Germany 1,181,000 living births and 31,800 stillbirths, a total of 1,212,800 births. Midwives in independent practice were in charge at 919,447 births and 32,327 miscarriages. In 1935, according to tentative reckoning, there were 1,265,000 living births, and the number of stillbirths has been estimated at around 34,000. This means a provisional total figure amounting to around 1,200,000. In the same year (1935) midwives were in charge at 971,970 births and 43,804 miscarriages. At the request of the National Association of Midwives, the representative professional organization of the group, the number of births for each practicing midwife was computed. In 1933 there were twenty-nine births to one midwife, in 1934 thirty-four births, in 1935 from thirty six to thirty-seven births. It will be noted that, on the basis of the more recent figures, the number of miscarriages at which midwives were in charge has increased by around 11,500. In the opinion of the *Deutsches Ärzteblatt*, the official organ of the medical profession, this figure may have resulted from a misinterpretation of the data or (what is more interesting) it may be ascribed to the fact that a smaller number of miscarriages were in charge of physicians. Pregnant women often themselves induce abortion and then call on the midwife for help. How the ministry of the interior has given especial attention to the situation of the midwives was previously reported (*THE JOURNAL*, July 6, 1935, p. 60). The ministerial policy has been gradually to reduce the number of midwives until an average of fifty confinements falls to the share of each.

In Germany independently practicing midwives are in charge at 75 per cent of all confinements, the other 25 per cent represent institutional confinements. The number of the latter has perhaps undergone a slight increase.

Death of Prof Paul Morawitz

Prof Paul Morawitz, distinguished clinician and director of the university clinic of internal medicine at Leipzig died July 1 aged 57. Morawitz had an excellent professional training. He first acquired a good background in physiology, which later formed the foundation of his clinical opinion. Among the professors under whom he worked as an assistant was Krehl of Heidelberg. While at Heidelberg, Morawitz obtained his first important appointment, the directorship of the University Medical Polyclinic at Freiburg. He was only 30 years of age at the time. Soon thereafter Morawitz became professor of inter-

nal medicine at Greifswald. Later he served in the same capacity at Wurzburg, succeeding finally to the celebrated chair of Strumpell at Leipzig. Morawitz was a prodigious and diligent worker who demanded a great deal of his assistants but enjoyed helping them along. He was beloved as a teacher. His clear diction and his high ideal of professional ethics made a permanent impression on many a young medical man. By the death of Morawitz the German universities have lost one of their ablest clinical professors.

AUSTRALIA

(From Our Regular Correspondent)

July 29, 1936

Psittacosis in Australia

During the summer of 1935-1936 seventeen instances of probable human infection of psittacosis were recognized in Victoria. Psittacosis virus has been demonstrated in the sputum of five of these patients. The most important sources of infection in Victoria are young newly captured birds, particularly cockatoos. The evidence suggests that maintenance of birds under crowded unhygienic conditions results in a lighting up of their naturally acquired infection with the virus. There were two proved human infections, which were apparently derived from aviary bred budgerigars (*Melopsittacus undulatus*).

Working under a grant for research on virus diseases from the Rockefeller Foundation and the department of health of the commonwealth of Australia, F. M. Burnet and Jean McNamara have published the results of their investigations into human psittacosis in Australia (*M. J. Australia* July 18). In the summer of 1934-1935 these investigators had found that a large proportion of recently caught individuals of *Psephenus haematotus* and *trichoglossus* (two species) and *Leptolophus hollandicus* were infected. It is possible that cases of this disease among human beings escaped recognition before the attention of physicians had been directed to the possibilities of infection by these two workers. It is considered that, in the case of the birds infection with psittacosis is very frequently contracted by young cockatoos in the nest but is usually overcome by the time they are captured, at least to the extent that the spleen no longer contains virus. If the young cockatoo, after capture, is kept under good conditions, it remains healthy and presents no danger to human beings. When, on the other hand, birds are crowded into small spaces with inadequate food and sunlight, their latent infection is lighted up.

The Australian experience with the human disease indicates that in children the disease is of a minor nature settling down in a few days, but that in adults, particularly in the elderly, the course of the disease is longer and the patient is much more seriously ill. There were no deaths in the series. Lung signs predominate, suggesting an atypical bronchial pneumonia but the lung signs are more extensive than the symptoms have led the physician to expect. The onset is almost influenzal in type, with malaise, severe headache and diarrhea as the common symptoms at this stage. The headache is not localized to any one part of the head but is so severe that the patient calls in medical attention relatively early. Eleven of the series were proved to be due to infection from the sulfur crested cockatoo (*Kakatoe galerita*).

The International Significance of a Bronchoscopic Operation

Early this year an Australian child named Kelvin Rodgers inhaled a nail into his lung. Australian surgeons considered themselves insufficiently experienced to attempt the removal of this foreign body, and he was referred to Chevalier Jackson for treatment. The successful outcome of this operation at the hands of this master of bronchoscopy has provided an incident which will act as a bridge of the happiest nature between two great English speaking countries. The incident

was the occasion for a statement by the premier of Victoria in the Victorian legislative assembly, July 1, in which he expressed the feelings of gratitude of the people of Australia. The premier referred to the incident as a striking reminder that science and humanitarian developments know no geographic boundaries.

In an editorial the *Argus*, the leading conservative daily newspaper of Victoria, developed the sense of gratitude even further. There is one man acknowledged by the world's surgeons as the great specialist in the field of bronchial surgery. The brevity of the operation in a few overcharged minutes of probing in a child's lungs for a nail may tend to obscure in our minds the training and preparation of a lifetime of study and practice which made the achievement possible. The perfection of instrument and technic that necessarily preceded the operation is to some extent forgotten in the relief that a great surgeon has succeeded. To that success nearly all the great pioneers of surgery have contributed in some measure. In the daring experiment let us not overlook the skill of instrument makers. The part played by the physicist in developing the modern technic of roentgenologic examination and diagnosis should be recognized. The efficiency and competence of a great array of people from hospital managers to nurses is important. To the amazing feat of this one man, all yielded something, and Dr. Jackson, to his great honor, was the only one to make light of his own part and to acknowledge the work of others.

The great traditions of medicine and the noble humanitarianism of its great doctors and surgeons have been worthily upheld. The world expects it but rarely stops to wonder how far it has a right to expect such high virtue and enlightenment in great practitioners. The part played in the achievement by communications and transport is also too easily forgotten. The concentration of resources for the one coordinated purpose of saving a life is surely a magnificent object lesson on the capabilities and resources of the modern social system. This one episode should stimulate acknowledgment of the vast volume of similar self sacrifice and devotion to duty that is traditionally associated with private surgery and the public hospital. The acknowledgment of Dr. Jackson's skill and generosity should be carried over to that great army of men and women who are daily performing similar acts of skill and devotion. The organization of medical services which freely places all the resources of medicine and surgery at the disposal of the people of this and other countries is something that calls for profound gratitude and admiration.

'The incident,' concludes the *Argus* "has fired the imagination of the people of Australia, and the measure of exultation in every mind is that our civilization is capable of such unselfish effort."

Survey of Orthopedic Cases

To ascertain the chief factors that cause crippling deformities in Australia, a preliminary survey has been made of the

Causes of Crippling Deformities

| | Victoria | New South Wales | South Australia | West Australia | Queensland |
|--|----------|------------------------|-----------------|----------------|------------|
| Tuberculosis of bones and joints | 16.9 | 7.2 | 22.0 | 3.7 | 4.3 |
| Poliomyelitis | 27.7 | 12.8 | 42.0 | 4.5 | 18.1 |
| Osteomyelitis | 26.2 | 22.8 | Not specified | 5.3 | 31.5 |
| Talipes | 12.3 | Not separately classed | 18.2 | 12.2 | 28.7 |
| Congenital dislocations | 10.2 | 11.0 | 10.8 | | |
| Congenital deformities including talipes | | 26.5 | | 10.0 | 8.6 |
| Spastic paraplegias | | 0.8 | 1.4 | 3.0 | 0.9 |

hospital statistics in the various states. The figures in the accompanying table are expressed as percentages of the total admissions for crippling deformities in each state.

While these figures can be accepted as indicating only a general trend, it is interesting to note how tuberculosis incidence diminishes toward the subtropical and tropical areas. The effect of poliomyelitis epidemics can be seen also in South Australia, Victoria and Queensland.

Ophthalmologist Retires

Having been associated with the Dunedin Hospital for fifty-two years as ophthalmic surgeon and dean of the Faculty of Medicine of the University of Otago for twenty-two years, Sir H. Lindo Ferguson has retired from the chair of ophthalmology in the university and from the active staff of Dunedin Hospital and Medical School. Sir Lindo is an honorary fellow of the American College of Surgeons and a fellow of the Royal Australasian College of Surgeons. He qualified at Dublin in 1880 and was the first ophthalmic surgeon in New Zealand.

MOSCOW

(From Our Regular Correspondent)

Aug. 23, 1936

Abortions Forbidden

In a previous letter (*THE JOURNAL*, August 1) information was given concerning the government bill on abortion, aid to lying-in women and families with many children. The decision of the Central Executive Committee of June 27 made this bill a law. Some changes have been made as the result of public discussion at numerous meetings as well as in the press. The operation of artificial abortion is completely forbidden everywhere, including hospitals, lying-in houses and the homes of physicians. The operation can be performed if a special commission will permit it; the only indications accepted by the law are a serious menace to the pregnant woman's health and severe hereditary diseases of the parents that can be transmitted to the child. If these conditions are not present, the physician as well as the person who seeks the abortion will be punished with two years' imprisonment and the pregnant woman with public censure and a fine. Another change in the new law is some decrease of alimony paid by the father for the children's maintenance after divorce: instead of one third of the salary for one child, a half for two and three fifths for three or more; the corresponding sums are one fourth, one third and one half. Mothers having six or more children receive premiums (the bill gave money premiums to women having seven or more children). The first claims for state allowances for 1,940 large families were received from forty-two districts of the Moscow province (excluding the city of Moscow). Already the building of new medical establishments, kindergartens and lying-in homes has begun.

The Institute of Experimental Medicine

In a decision on the work of the Gorky All-Union Institute of Experimental Medicine the Council of People's Commissars of the Soviet Union noted that its medical workers have made a detailed study of the human organism and that it has become a basic scientific institution. At the same time the council states that the work lags behind the level of modern medical achievements. The clinical work is not properly organized, for which the commissariats of health are responsible. Therefore the institute must reconstruct its work, giving consideration to the experience of other countries. Special attention must be paid to the solution of important problems in the treatment of cancer, tuberculosis, influenza, malaria, typhus, scarlet fever and rheumatism. The institute will have 400 clinical beds in Moscow. There as well as in other institutions under the guidance of the Institute of Experimental Medicine new methods of treatment will be tested and worked out.

For the rapid application of the methods that it works out, the Institute of Experimental Medicine must provide facilities for giving instruction to a hundred persons a year. It must

work in connection with other establishments for scientific research and be active in organizing medical conferences and congresses. The principal work of the institute is carried on in Moscow and Leningrad, but it has a subtropical department at Sukhum on the Black Sea, where experimental work is done with monkeys. The institute is instructed to publish an annual report of its work in Russian, French, English and German.

League of Nations Hygienic Committee

A session of the Hygiene Committee of the League of Nations was held June 22-27 in Moscow. The head of the committee, Thorvald Madsen of Copenhagen, the head of the Public Hygiene Bureau, Joseph Jitta of Paris, Jacques Parisot of Nancy, G. Pittaluga of Madrid, Montague Morgan of London, Charles Winslow of the United States, Elmer McCollum of Columbia University and many other foreign guests were present. The Soviet scientists V. Bronner, venereologist, A. Sisin, hygienist, P. Sergiev, malariologist, L. Stern, physiologist, and others took part in the proceedings. At the first meeting G. N. Kaminsky, the people's commissar of health, greeted the session and spoke of the increase of population in our country as being 3,000,000 persons a year, while the mortality rate is much less than in the prerevolution period. Professor Parisot made a report about the activity of the hygiene organization of the league in rural hygiene.

For better acquaintance with the hygiene in rural districts the foreign members of the session visited regional and district hospitals, kindergartens and other medical establishments of our country. They made a trip to Gorky, Leningrad, Rostov-on-Don and the Georgian and Ukrainian republics. They saw the health resorts, the spas, and the climatic and balneologic stations on the shore of the Black Sea and in the Crimea.

After the Moscow session was ended, the Section of Information of the League secretariat published a paper in which the development of medical aid in the Soviet Union is mentioned.

The Commissariat of Health

Instead of the separate health commissariats that existed in every Soviet republic, the government resolved to establish an All-Union Health Commissariat with Dr. Gregory N. Kaminsky (former people's commissar of health in the Russian Soviet Republic) at its head. The new commissariat is to unite in one system and plan the care of the people's health in the Soviet Union. Sums given for this purpose have been increased from 5,365 million roubles in 1929-1932 to 17,870 millions in 1933-1936. The All-Union Health Commissariat will develop great activity in measures for the elimination of venereal diseases, tuberculosis and rheumatism. The laboratory and medical equipment of hospitals and scientific establishments will be greatly improved. Simultaneously with the building of regional hospitals for 200-250 beds with all types of qualified medical and laboratory aid, the new commissariat will found well equipped interregional hospitals. The improvement of medical aid administered to workmen of heavy industries—principally metallurgic, coal mine and chemical—the study of occupational diseases and their treatment are one of the principal aims of the new commissariat. Many problems confront the new commissariat in all of them in the front rank being the care taken of living man—a struggle for health, elimination of obstacles to normal growth of the new Soviet generation, the prolongation of life and the encouragement of efficiency.

Blood Transfusion

A new decree on blood transfusion in the Soviet Union was recently published. Every person older than 18 if of sound mind and of normal physical development can be voluntarily enrolled among the number of donors. The average quantity of blood required from a new donor is 150-200 cc. The donation of blood for transfusion is to be repeated not more than seven times a year when the maximal quantity is taken.

Marriages

EDWARD M ANDERSON, Iamberton, Minn to Miss Mabel Gilland of Sleepy Eye, in Minneapolis June 4

ANTHONY JOSEPH BARRANCO, Bartow, Fla, to Miss Fannie De John at Birmingham, Ala July 28

ROBERT JENNINGS BAKER, Charleston, S C, to Miss Anne Hunter Linley of Anderson, June 27

RAYMOND F HEDIN to Miss Lydia Elizabeth Anderson, both of Red Wing, Minn, June 19

ALVIN ERICKSON Hendricks Minn, to Miss Marion Piltingsrud of Leeds, N D, June 12

JOHN J BOEHNER JR. to Miss Jeanne Kathryn Halloran, both of Minneapolis, June 15

JOSEPH HOWARD SIEGFRIED to Miss Mary Elizabeth Easton both of Peoria, Ill, August 7

HORACE CRAIG GIBSON to Miss Mary Louise Thomas both of Charlotte, N C, recently

THEODORE MYRON DEUTSCH to Miss Selma Klausner both of Brooklyn, recently

Deaths

George Abraham Torrison, Chicago, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, member of the Illinois State Medical Society, associate clinical professor of laryngology and otology, Rush Medical College fellow of the American College of Surgeons, aged 71, attending laryngologist to the Lutheran Deaconess Home and Hospital and Lutheran Memorial Hospital, assistant attending laryngologist to the Presbyterian Hospital, where he died, June 20, of pulmonary tuberculosis

James Madison Baird, Columbus, Ga Kentucky School of Medicine, Louisville, 1892, Eclectic Medical Institute Cincinnati, 1893, Homeopathic Medical College of Missouri St Louis, 1898 member of the Medical Association of Georgia, past president of the Muscogee County Medical Society, president of the Georgia State Board of Medical Examiners, formerly on the staff of the Columbus City Hospital, aged 66, died, July 10, in the Piedmont Hospital, Atlanta, of coronary occlusion

Joseph Barnes Bacon, Macomb, Ill Texas Medical College and Hospital, Galveston 1879 Chicago Medical College, 1881, member of the Illinois State Medical Society fellow of the American College of Surgeons at one time instructor in surgery at the Northwestern University Medical School, Chicago, for many years surgeon for the Burlington Railway, formerly on the staff of St Francis Hospital, aged 82, died, July 21 of carcinoma of the rectum

Marion Earle Brown New Orleans Tulane University of Louisiana Medical Department, New Orleans 1911 member of the American Academy of Ophthalmology and Otolaryngology, professor of ophthalmology Tulane University Graduate School of Medicine, served during the World War on the staff of the Eye, Ear, Nose and Throat Hospital, aged 50, died, August 19

Russell Montague Young, Lima, Ohio Rush Medical College Chicago, 1900 member of the Ohio State Medical Association, veteran of the Spanish-American and World Wars, on the staffs of the Lima Memorial and St Rita's hospitals, aged 59, died, June 21, as the result of a spinal injury received in a fall several months previously

Russel Murray Rome Brooklyn Long Island College Hospital Brooklyn, 1901, formerly clinical professor of surgery at his alma mater fellow of the American College of Surgeons surgeon to the Kings County and Bushwick hospitals, aged 57, died June 24 at his summer home in Shelter Island N Y of coronary thrombosis

Anthony Bernard Zwaska, Beloit, Wis Marquette University School of Medicine Milwaukee, 1915 member of the State Medical Society of Wisconsin served during the World War on the staff of the Beloit Municipal Hospital, aged 45, died June 30 in Rochester Minn of hypertension and uremia

Robert Astley Rice, Fitchburg Mass, Harvard University Medical School Boston 1902 member of the Massachusetts Medical Society served during the World War, formerly

city and school physician, aged 60, died, June 13, in the Burbank Hospital, of arteriosclerosis and chronic myocarditis

Herman Reinsch Chicago Chicago College of Medicine and Surgery 1912 fellow of the American College of Surgeons served during the World War, aged 48, member of the staff of St Francis Hospital, Evanston where he died, June 14, of coronary thrombosis, while visiting patients

Felix Melville Scott, Paragould Ark Vanderbilt University School of Medicine, Nashville, Tenn, 1881, member of the Arkansas Medical Society, past president and secretary of the Greene County Medical Society county health officer, aged 82, died, June 17, of bronchopneumonia

Jesse J Saxton, Tampa Fla Eclectic Medical Institute, Cincinnati 1907 member of the Florida Medical Association past president of the Hillsborough County Medical Society, aged 56, died, June 29 in St Luke's Hospital, Jacksonville, of injuries received in an automobile accident

Austin David Bates Denton, Texas Rush Medical College Chicago, 1922 secretary of the Denton County Medical Society served during the World War, aged 43, died, July 18 in the Dallas (Texas) Medical and Surgical Clinic Hospital of coronary occlusion and arthritis

Rodrigue Mignault, Lowell Mass, M B Laval University Medical Faculty, Montreal, Que, Canada 1882, M D, School of Medicine and Surgery of Montreal 1884, member of the Massachusetts Medical Society, for many years school physician, aged 73, died, June 26

John Denniston Wilson Scranton, Pa Jefferson Medical College of Philadelphia, 1905, fellow of the American College of Physicians veteran of the Spanish-American War on the staff of the Scranton State Hospital, aged 56, died, June 20 of coronary artery disease

Blackburn George Tucker, Nashville, Tenn, Vanderbilt University School of Medicine Nashville 1897, at one time county health officer medical superintendent of the Davidson County Tuberculosis Hospital, aged 60, died, June 22, in a local hospital of pneumonia

John James Quinn Lansford Pa, University of Pennsylvania School of Medicine Philadelphia 1917 past president of the Carbon County Medical Society served during the World War, aged 46, died, June 23 of traumatic gastroptosis with multiple adhesions

Buchanan S Wert Chattanooga, Tenn, University of Louisville (Ky) Medical Department, 1879 past president of the Chattanooga and Hamilton County Medical Society, on the staff of the Erlanger Hospital, aged 79, died June 20, of coronary thrombosis

Francis Joseph Pfeffer, Quincy, Ill Washington University School of Medicine, St Louis, 1895 served during the World War, aged 63, died, June 16, in the Veterans Administration Facility Jefferson Barracks, Mo, of myocarditis and coronary thrombosis

Lyman E Rockwell, Amenia N Y University of the City of New York Medical Department 1873 member of the Medical Society of the State of New York for many years health officer of Amenia, aged 90, died June 11, of cerebral hemorrhage

Florence Harvey Tresilian, Hudson Mass Boston University School of Medicine 1895 formerly on the staffs of the Gardner (Mass) State Hospital and the Taunton (Mass) State Hospital, aged 80, died, June 26 in the Flower Hospital New York

Wallace Emery Bray, Delavan Wis Northwestern University Medical School Chicago 1934 formerly on the staff of the Southern Wisconsin Colony and Training School, Union Grove, aged 33, died, July 2, of an overdose of a barbitual compound

Mitchell Sisson, Boston Harvard University Medical School, Boston 1913, member of the Massachusetts Medical Society for many years school physician for the school district of East Boston, aged 49, died June 1, of melanotic sarcoma

William W Core, Nashville, Tenn Vanderbilt University School of Medicine, Nashville 1880, formerly county health officer, aged 76 for many years medical superintendent of the Davidson County Hospital where he died, June 3, of influenza

William Edward Holmes Morse, Oakland Calif, University of Michigan Department of Medicine and Surgery Ann Arbor 1885, aged 74, died June 4, in the Alameda County Hospital of shock following an operation on the bladder

Ethbert Cole Rosamond, Birmingham, Ala., Louisville (Ky.) Medical College, 1893, member of the Medical Association of the State of Alabama, on the staff of the Norwood Hospital, aged 65, died, June 16, of coronary occlusion

George W. Snively, Dalton, Ohio, Medical College of Ohio, Cincinnati, 1900, member of the Ohio State Medical Association, aged 70, died, June 4, in the City Hospital, Massillon, of cerebral hemorrhage and arteriosclerosis

George Washington Bamberger, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, aged 56, died, July 9, in the Michael Reese Hospital, of carcinoma of the stomach

Ludwig Amster, Flushing, N. Y., University of the City of New York Medical Department, 1888, formerly a practitioner in Atlanta, Ga., was one of the founders of the Piedmont Hospital, Atlanta, aged 72, died, July 2

Louis P. Reimann, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1883, aged 83, died, June 1, in the Lankenau Hospital, of bronchopneumonia, arteriosclerosis and coronary sclerosis

William Albert O'Connor, Chicago, University of Illinois College of Medicine, Chicago, 1914, served during the World War, aged 50, died, June 25, in the Wesley Memorial Hospital, of hypertensive heart disease

Mary Dunn Crane, Columbus, Ohio, Woman's Medical College of Cincinnati, 1893, aged 81, died, June 22, in the S. M. Heller Memorial Hospital, Napoleon, of burns received when an oil stove overturned

Thomas Walter Raper, Williamsport, Pa., Jefferson Medical College of Philadelphia, 1897, member of the Medical Society of the State of Pennsylvania, aged 78, died, June 29, of carcinoma of the prostate.

Benjamin Randal Ballard, Kinston, Ala., University of Tennessee Medical Department, Nashville, 1894, aged 65, died, July 10, in a hospital at Montgomery, of sepsis due to a carbuncle on the neck

Ehme E. Aukes, Lincoln, Neb., Georg-August-Universität Medizinische Fakultät, Göttingen Prussia, Germany, 1877, aged 84, died, July 17, of cerebral hemorrhage, arteriosclerosis and hypertension

General Pinnell, Miami, Okla., Memphis (Tenn.) Hospital Medical College, 1902, member of the Oklahoma State Medical Association, aged 58, died, June 15, in a hospital at Tulsa, of heart disease

Joseph Price Tunis, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1889, aged 70, died, June 10, of myocarditis, hypertrophy of the prostate and chronic cystitis

Wilfred Freeman Gove, Wareham, Mass., Boston University School of Medicine, 1926, member of the Massachusetts Medical Society, aged 40, died, June 26, of acute monocytic leukemia

William Henry Davis, Creston, Iowa, Bennett College of Eclectic Medicine and Surgery, Chicago, 1887, Marion-Sims College of Medicine, St. Louis, 1893, aged 80, died, June 10, of myocarditis

Joseph C. Culp, Thayer, Mo., Marion-Sims College of Medicine, St. Louis, 1892, member of the Missouri State Medical Association, aged 80, died, June 27, of chronic nephritis and uremia

William Lorenzo Shank, Lee, Ill., Central College of Physicians and Surgeons, Indianapolis, 1894, aged 69, died, June 1, in the East Side Hospital, Waterman, of coronary thrombosis

John Francis Riordan, Kenosha, Wis., Northwestern University Medical School, Chicago, 1905, aged 58, died, June 14, in St. Catharine's Hospital, of myocarditis and hypostatic pneumonia

George Asher Strader, New York, Hahnemann Medical College and Hospital of Philadelphia, 1902, aged 63, died, June 27, at his summer home in Norway, Me., of angina pectoris

Leonard Clair Baldauf, Erie, Pa., Jefferson Medical College of Philadelphia, 1926, member of the Medical Society of the State of Pennsylvania, aged 35, died, July 5, of heart disease

Curtis Albert Bailey ♂ Athens, La., Louisville (Ky.) Medical College, 1890, past president of the Claiborne Parish Medical Society, aged 67, died suddenly, July 15, of heart disease

Jay Harry Barto, St. Louis, Missouri Medical College St. Louis, 1897, aged 66, member of the staff of the Missouri Baptist Hospital, where he died, July 4, of cerebral hemorrhage

Samuel Jay Barker, Largo, Fla., Missouri Medical College, St. Louis, 1883, formerly a practitioner in St. Louis, aged 78, died, July 1, of myocarditis and chronic nephritis

Thomas Joy Putnam, Springfield, Mass., Homeopathic Hospital College, Cleveland, 1877, aged 86, died, June 10, in the Wesson Memorial Hospital, of cerebral hemorrhage

Frank W. Adriance, Elmira, N. Y., Hahnemann Medical College of Philadelphia, 1877, aged 81, died, July 24, of cardiac decompensation and hypertrophy of the prostate

Eyer Walter, Williamsport, Pa., Jefferson Medical College of Philadelphia, 1880, aged 82, died, June 2, in the Williamsport Hospital, of myocarditis and acute cholecystitis

Christopher Peters Walter, Lyman, S. C., Medical College of the State of South Carolina, Charleston, 1885, aged 82, died, June 25, of sarcoma of the bladder

Maurice Watson, Manchester, N. H., Dartmouth Medical School, Hanover, 1901, aged 62, died, June 22, at his summer home in Gilmanton, of bronchopneumonia

Sinclair Kirtley Royle, Patchogue, N. Y., New York University Medical College, 1896, aged 76, died, June 25, of bronchopneumonia and pernicious anemia

Charles Henry Brewer, Stayton, Ore., Willamette University Medical Department, Salem, 1898, at one time mayor, aged 57, died, July 16, of heart disease

Garland M. Vaden, Capeville, Va., University College of Medicine, Richmond, Va., 1901, member of the Medical Society of Virginia, aged 58, died, June 20

Van Lear Polk, Chicago, Meharry Medical College, Nashville, Tenn., 1919, aged 43, died, June 26, in Proviso Township, of carcinoma of the tongue.

Ephraim Le Rue Walmer, Harrisburg, Pa., Jefferson Medical College of Philadelphia, 1891, aged 73, died, June 22, of chronic nephritis and uremia

Daniel Sickler, Ogden, Iowa, Albany (N. Y.) Medical College, 1879, for many years mayor of Ogden, aged 85, died, June 19, of chronic myocarditis

Joseph Guardith Moore ♂ Philadelphia, Temple University School of Medicine Philadelphia, 1918, aged 56, died, June 6, of chronic myocarditis

Carl Johan Anderson, Porter, Okla., Bennett College of Eclectic Medicine and Surgery, Chicago, 1898, aged 72, died in June, of pernicious anemia

Sherman T. Lewis, Menard, Ill., Northwestern University Medical School, Chicago, 1892, aged 69, died, June 20, of cerebral arteriosclerosis

C. Roland Per Due, Indianapolis, Central College of Physicians and Surgeons, Indianapolis, 1897, aged 62, died, June 15, of coronary occlusion

Rufus Austin Black, West Sullivan, Maine, College of Physicians and Surgeons, Boston, 1905, aged 54, died, June 1, of acute myocarditis

Anton Radesinsky, Chicago, Medizinische Fakultät der Universität Wien, Austria, 1894, aged 69, died, June 18, of cerebral thrombosis

Thomas D. Palmer, Elk City, Okla., Columbian Medical College, Kansas City, Mo., 1901, aged 66, died, June 15, of paralysis agitans

John Hepburn Lloyd, Erie, Pa., Jefferson Medical College of Philadelphia, 1896, aged 62, died, June 2, of pulmonary tuberculosis

Charles Albert Orr ♂ Crafton, Pa., Jefferson Medical College of Philadelphia, 1901, aged 65, died, June 6, of myocarditis

CORRECTIONS

Not Dead—The report of the death of Dr. William Preston Haynes of Washington, D. C., received in this office from the Commission on Licensure of the District of Columbia and published in the obituary columns of *THE JOURNAL*, September 12, page 893, was erroneous. Dr. Haynes writes that he is alive and was never in better health.—Dr. Hermann Frederick Erben was erroneously reported as having died in Calcutta, India, in various newspapers, and in the obituary columns of *THE JOURNAL*, June 13, page 2087. Dr. Erben recently wrote from New York City that the report of his death in Calcutta was grossly exaggerated.

Correspondence

CLASSIFICATION OF ARTHRITIS

To the Editor—Desirable as it may be, it is often impossible neatly to define and classify clinical syndromes the origin of which is unknown. Nowhere is this better illustrated than in the report of the transactions of the American Association for the Study and Control of Rheumatic Disease, which appeared in THE JOURNAL August 8. An analysis of this report shows that classification may at times obscure as readily as it may clarify a clinical problem. It is all very well to tack labels on morbid processes, but labels have a way of wearing thin and then our underlying ignorance is more clearly exposed.

Much was said at the conference about the belief that rheumatoid arthritis and osteo-arthritis are clinically and pathologically different and that the terms represent two different diseases. Very little was said about the concept supported by me and by others (THE JOURNAL, May 5, 1934, p 1449) that these terms are merely labels to distinguish clinical variants of the same disease. A few words in support of this point of view may not be amiss.

It has been clearly shown that trauma, specific infections such as syphilis, and at least one metabolic irritant (the urates in gout) may produce proliferative arthritis or degenerative osteo-arthritis, depending for the most part on factors other than those of causation (*New England J Med* 213 799 [Oct. 24] 1935). Proceeding from the known to the unknown, it seems reasonable to believe that a similar group of irritants may be the primary cause of proliferative or degenerative pathologic changes in the arthritides of unknown origin. Nor is the logic of this conclusion greatly affected by variations in the nonfilament count, sedimentation rate or even agglutination tests in rheumatoid and osteo arthritis. If a specific infectious agent such as *Spirochaeta pallida* can produce in one patient a proliferative type of arthritis and in another individual a degenerative type of osteo-arthritis there is good reason to believe that some as yet unknown infectious agent may affect principally the synovial membrane in one type of patient resulting in nonspecific rheumatoid arthritis, and the articular cartilage in another type of individual, resulting in nonspecific osteo-arthritis. The same reasoning would seem to apply to trauma, extrinsic or intrinsic, and likewise to some hypothetical metabolic irritant that may be operative in the causation of nonspecific arthritis. Indeed, it is my opinion that nonspecific rheumatoid arthritis and osteo-arthritis are not produced by any single irritant but may result from multiple causes.

Then, of course, there is the second and almost insuperable argument against a sharp division of rheumatoid arthritis from osteo arthritis. Today it is freely admitted by practically all students of the subject that the two forms of the disease occur frequently in the same patient in the same finger, even in the same joint. The explanation which has been advanced, that in all such instances two different diseases have been superimposed on each other, is in my opinion unacceptable and contrary to my observation and experience. As Dr Jordan stated at the conference, 'In many instances the two seem to be intertwined in the one patient to such an extent that it is difficult to draw any hard and fast line between them.' As Morrison and Kuhns have recently stated, "The day may not be far distant when division of types in chronic arthritis will become obsolete and articular changes will be looked upon as signs of a general physiological disturbance, varying in their nature largely with the anatomic type and age of the individual."

To those who are skeptical of the unitarian concept of the etiology of nonspecific arthritis may be commended the suggestion of Dr Key—the study of the synovial membrane in

cases diagnosed as osteo-arthritis. It is such a study that has convinced me of the essential unity of proliferative and degenerative arthritis, and it was this type of investigation that convinced Knaggs, Nichols and Richardson, and others, of the validity of the unitarian concept of the etiology of chronic nonspecific arthritis.

I cannot concur with Dr Jordan that there is no compromise possible between those who believe that we are dealing with two diseases and those who think that proliferative and degenerative arthritis are different manifestations of the same disease.

Would not the following statements be a fair exposition of the status quo, which might be acceptable to both sides of this controversy? The primary agent or agents that are the cause of rheumatoid arthritis and osteo-arthritis are unknown. There are nevertheless two concepts regarding the etiology of these two forms of nonspecific arthritis: (1) that proliferative rheumatoid arthritis and degenerative osteo-arthritis are two different diseases and are due to different etiologic agents, and (2) that rheumatoid arthritis and osteo-arthritis are different manifestations of the same disease and are the result of the same etiologic agent or group of agents.

Quite clearly, future investigation will have to determine which concept is correct.

BENJAMIN H. ARCHER, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

USE OF CAMPHORIC ACID

To the Editor—In Beckman's "Treatment in General Practice" edition 2, page 245, there appears the following prescription:

| | |
|---------------------|------|
| Camphoric acid | dr 4 |
| Alcohol | ou 2 |
| Mucilage of acacia | ou 3 |
| Syrup of orange q s | ou 6 |

I have been unable to fill the prescription owing to the fact that alcohol added to the acacia or acacia added to the alcohol causes the formation of a white gummy material impossible to break up. How can this prescription be filled? (The mucilage was made up fresh according to directions given in Remington's "Practice of Pharmacy.") If the prescription is an impossibility can you suggest another method for getting camphoric acid in solution with a pleasant tasting vehicle?

REUBEN HOFFMAN, M.D., Henryton, Md.

ANSWER.—The prescription can be satisfactorily compounded if the following instructions are carefully heeded:

Place the freshly prepared mucilage of acacia in a clean mortar, add 4 drachms (15 cc) of syrup of orange, and stir the two together vigorously with a pestle. Then dissolve the camphoric acid in the alcohol separately and slowly add this solution to the mixture in the mortar with constant stirring. The white gummy flocculent material that appears will gradually disappear during ten minutes of vigorous trituration with the pestle. The mixture may then be poured into the dispensing bottle, which should bear a 'shake' label, it will be muddy in appearance and only translucent because these are the properties of the mucilage of acacia but will be a satisfactory suspension for administration from a bottle.

In the textbook referred to there are listed on page 785 several vehicles of an alcoholic content from 45 to 75 per cent any of which will satisfactorily dissolve the camphoric acid and should thus be simpler to use in extemporaneous compounding. A prescription using one of these vehicles, which would be red and not unpleasant in taste, would appear as follows:

| | Gm or Cc | |
|-------------------------------|--------------|-------|
| Camphoric acid | 150 | 3 iv |
| Compound tincture of cardamom | to make 1800 | 3 vii |

For other tastes the compound tincture of cinchona which would give a brown solution, might be preferable. Indeed any one of the higher alcoholic vehicles will satisfactorily dissolve the

camphoric acid without losing transparency or any other of its desirable properties. The lower alcoholic vehicles, however, such as the well known aromatic elixir, will not completely dissolve the drug.

CHRONIC POTASSIUM CYANIDE POISONING

To the Editor—I am unable to find definite or detailed descriptions of chronic potassium cyanide poisoning symptoms. One of my patients a man 79 years old has worked for a year past in a room about 40 by 15 feet in dimension in which were two potassium cyanide furnaces (for case hardening steel) which were heated to 1600 F for ten hours daily. There was no special ventilation in the room though an apparatus for proper ventilation has since been installed. He worked under these circumstances about a year, during which time he noticed on occasion that a white dust collected on all objects in the room (when freshly loaded furnaces were in operation little dust was noticed but when the level of the material in the furnaces got lower the dust was more noticeable). He never worked on Saturday or Sunday. On Monday Dec. 2, 1935 he became suddenly and violently ill. He had arisen half an hour earlier than usual feeling perfectly well but before he could get dressed he was seized with intense pain across his chest, back abdomen and down to his hips. He does not remember being dyspneic but he writhed with pain and broke into a cold clammy sweat. He got to bed had an electric pad took a dose of aromatic spirit of ammonia and was somewhat relieved when I first saw him. His convalescence has been very slow for six weeks. His appetite is very poor and he feels weak. The pain in the chest abdomen and back lasted four weeks and then gradually improved. He had little blisters in his nose (on the septum and alae) for a month or so before the acute attack. These disappeared about two weeks after the attack. Will you please tell me whether or not such symptoms are due to chronic cyanide poisoning? Can they appear forty-eight hours after exposure has ceased? Will you give me any references on the subject that will help me find a good description of the effects of chronic potassium cyanide exposure? In a report of the Commission on Occupational Diseases to Charles S. Deneen a reference to photo-engravers using potassium cyanide is mentioned stating the symptoms to be nausea, loss of appetite and general disinclination to work stating that it occurs after six or seven weeks exposure and is especially likely to recur in two or three weeks and is then likely to be fatal. Do you think that it is likely that my man will have a recurrence if he attempts this job again now that proper ventilation is provided? M. D. Pennsylvania

ANSWER.—The use of potassium cyanide in the heat treatment of metals has led to little evidence of harm to exposed workmen. In many large establishments there may be as many as fifty cyanide pots. Around these pots the waste cyanide material is ground into fine dust. Janitors sweep these floor areas without any precautions, leading to visible clouds of dust, some of which is cyanide. The clothes of workmen may become coated with cyanide incrustations. The lunches of workmen may be seen lying on the lip of the cyanide pots, to be kept warm until consumed. Workmen eat their food without washing their hands and with utter lack of concern as to hazardous chemicals all about them. This experience, which has been shared by many industrial hygienists, has led to the opinion that industrial exposure to cyanides provides only a low order of risk. This does not imply that cyanides are not poisonous but instead only that in industry few acute and fewer chronic poisonings from such agents ever have come to light. The fatal dosage of potassium cyanide, when taken internally, is about 0.2 Gm.

Both acute and chronic poisoning are discussed in the following publications:

Collins and Martland *J. Nerv. & Ment. Dis.* 35: 417, 1908.
Peterson, Frederick, Haines, W. S. and Webster, R. W. *Legal Medicine and Toxicology*. Philadelphia: W. B. Saunders Company, 1926.
International Labor Office. *Occupation and Health*. Geneva, 1934.

The chief symptoms of chronic poisoning are given by Peterson, Haines and Webster as follows:

A form of chronic poisoning is stated to occur among gilders, photographers and others who are engaged in the handling of hydrocyanic acid, potassium or sodium cyanide. The symptoms are stated to be headache, vertigo, paleness of the face, loss of appetite, offensive breath and difficult respiration. Collins and Martland reported a case of chronic poisoning in a silver polisher in which the symptoms were scarcely distinguishable from those of an anterior poliomyelitis: paralysis of the limbs and muscular atrophy but with a certain degree of recovery. Chronic poisoning by hydrocyanic acid does not, however, seem to be a frequent result of the long-continued exposure to the gas. An irritation of the skin of the face like acne rosacea is described.

The occurrence of any chronic poisoning as the sole manifestation of cyanide poisoning is open to question. The cyanides, apart from being local irritants, act as asphyxiants. The nature of the asphyxiation is peculiar in that the tissues themselves are rendered unable to take up oxygen from the arterial blood. The venous blood remains the same color as the bright red contents of arteries. A delayed action is not known. A delay of forty-eight hours is highly improbable. To the contrary, cyanogen compounds are accorded first or near first rank in exerting toxic action instantaneously—within a few seconds.

The manifestations described in a workman 79 years of age away from work for two days, may with no assurance be associated within potassium cyanide as the cause. The skin lesions described may very well have arisen from cyanide dust or fume as cyanide dermatitis is relatively common. The gross lack of sanitation described in the first portion of this reply is not condoned, but it is difficult to procure the cooperation of industrialists when the evidence of practical hazards is so meager. Nonfatal cyanide poisoning is ordinarily followed by complete recovery, with no known predilection for subsequent attacks in the absence of an adequate new exposure. However in the case of a workman in his eightieth year there may be good reason for the avoidance of further exposure to cyanide or to any other distinct occupational hazard.

VARICOSE VEINS WITH PHLEBITIS

To the Editor—I have a patient a married woman, aged 36 who came to see me regarding painful varicose veins. These varicosities developed after her second pregnancy. They are superficial tortuous and extend from the ankle as far as the knee. They are present on the left leg only. During her menstrual period the veins become markedly engorged and enlarged and they are extremely painful especially at the ankle. The pain is so severe that the patient has to keep off her feet. At the time of the flow the ankle presents a bunch of superficial varicosities painful to touch. I was called to see the patient today (this is not her menstrual time). She complained of severe pain in the left leg the pain coming on suddenly without any warning and while she was sitting in a chair. Examination revealed thin tortuous superficial veins extending from the ankle to the knee. There were three red spots between the knee and the saphenous opening these spots were fairly painful to digital pressure. Apparently there is at present some phlebotic condition. I ordered the patient to stay in bed, elevate the leg and apply ice. Would it be proper to institute the injection treatment of the veins sometime in the future for the abolition of them? If there is any other method of easing the severe pain in the ankle and leg will you kindly inform me? Please omit name.

M. D. Connecticut.

ANSWER.—From the available data one can gather that the patient suffers from a patchy type of phlebitis of a preexisting varicose vein. The development of these venous dilatations following pregnancy and the increasing discomfort during menstruation are suggestive of a pelvic thrombosis as the cause of varicosities. Whether or not any obliterative treatment is advisable will depend on two factors: the patency of the deep veins and the activity of the infection in the veins. To determine the former the test of Perthes is most informative. With the patient in the standing position a towel or a rubber band is thrown round the thigh and enough compression is exerted to obliterate the saphenous but not the femoral vein. Next the patient is asked to bend and extend the knee vigorously and in rapid succession ten times. If the deep veins are patent the superficial varicosities will diminish in size, as the blood will be squeezed and aspirated into the deep venous circulation. Releasing now the constricting towel results in a refilling of the varicosities from above, indicating the amount of blood that has passed into the deep venous bed following exercise. If there is no appreciable diminution of the size of the veins after muscular exercise either the deep circulation is obstructed or there is an increase in venous pressure owing to valvular incompetence of the iliofemoral vein so that blood cannot pass readily through the communicating branches.

If injections are made in patients with deep venous obstruction or valvular incompetence, there may be an increase in edema and there is bound to be a recurrence, as the increased deep venous pressure will open the obliterated veins or force its way into new channels.

Even more important is the recognition of infection in the varicosities, because an injection into a vein harboring manifest or latent infection is often followed by a reactivation of the phlebitis, which, in case of a latent pelvic phlebitis may even extend into the pelvis with the production of a typical deep thrombophlebitis, a milkleg.

In the given case, elevation with hot boric acid dressings should rapidly ease the pain. Ice sometimes aggravates the neuritis that often accompanies an acute or subsiding phlebitis. If there is no swelling of the ankle and no evidence of deep thrombosis, and the patient's temperature and pulse are normal she may be allowed to get up with an Unna's paste boot or an elastic stocking. Later the white count and especially the sedimentation rate will give a fair estimate of the presence of residual infection. This infection may have subsided in six months or may be present after ten years especially if other foci of infection have not been eradicated.

Further information on this problem requiring considerable clinical experience can be obtained by writing for a bulletin on the Varicose Vein Exhibit of the American Medical Association shown in Philadelphia in 1931, enclosing a 10 cent stamp.

GONORRHOEA IN WOMEN

To the Editor—About two years ago a female patient contracted a gonorrhoeal infection. I saw her March 15, 1934 at which time she had gonococcal involvement of endocervix. This cleared up under local treatment. Apparently there was no involvement of the tubes. Smears were negative. In September 1935 following a menorrhagia she again developed a vaginal discharge, which was positive for the gonococcus. At this time there was slight tenderness and swelling of the right tube. There was no elevation of temperature. I began using nonspecific protein with local treatment and the discharge soon stopped. I later used a gonococcus filtrate intradermally as there was still slight tenderness of the right tube which was still palpable. At the present time smears following menstruation from the cervix are negative. The tube is not tender but there is a strongly positive complement fixation test. Is this significant and what can be done about it? Please omit name and address. MD Ohio

ANSWER—A positive complement fixation test means that the patient has specific gonococcus antibodies still present in the blood stream. Since such specific antibodies are found only when gonococci are present in the body and disappear within several weeks after the disappearance of the gonococci a careful search for the residual infection must be made. Such a residual infection may be found in the deeper cervical glands but is more frequently found in Skene's ducts or in Bartholin glands. If the latter are palpable and enlarged, they are pathologic and should be removed by radical surgical excision. Skene's ducts demand especial attention since chronic infections are more persistent here than elsewhere in the female genital tract. If a secretion can be expressed from them by digital pressure or if they are thickened and cordlike, the duct outlets should be located in the floor of the urethra or immediately adjacent to the external urinary meatus, threaded on the blunt end of a needle and excised (see Curtis Textbook of Gynecology, Philadelphia and London, W B Saunders Company, 1934).

The possibility of reinfection must also be borne in mind since the patient had apparently at least one reinfection. A male partner with a chronic infection can produce repeated infections in his partner. Coitus should therefore be forbidden under these circumstances.

THROMBO ANGIITIS OBLITERANS

To the Editor—A patient gives a history of intermittent claudication that is a dull ache in the left leg on walking several blocks relieved by rest. This first began four years ago and he has had several attacks so severe that he was put to bed and once his leg was opened up and drained. Although the condition has been present continuously he has had spells when it is worse especially in the winter. This affects only the left foot the right one feels normal. He also complains of easy chilling of the left foot and he has noticed that the left toe nails grow much slower than the right. He has noticed too that the left foot often gets fiery red when in a dependent position. At present there is exquisite tenderness on pressure over the anterior midportion of the leg. He is a man, aged 43 of French and German ancestry. He states that he has never had syphilis and he smokes about a pack of cigarettes daily. He gives a history of migrating transient soreness over various parts of the body. He is 67½ inches (170.5 cm) tall and weighs 165 pounds (75 Kg). The temperature is 98.4 F pulse 65 respiration 17. The systolic blood pressure is 115 diastolic 78. Red blood cells number 4,890,000 the hemoglobin is 90 per cent the white blood cells number 8,600. The Wassermann reaction is negative. He has four crowned teeth which have not yet been investigated as to the presence of infection. The eye grounds show fullness of the veins but his physical examination is good otherwise except for the left leg. The dorsalis pedis pulse is absent the posterior tibial faint the foot shows dependent rubor and elevation pallor. There is slight swelling about the external malleolus and rather marked tenderness along the large vessels of the calf of the left leg. I have made a diagnosis of thrombo-angitis obliterans. I have forbidden him the use of tobacco and contemplate putting him to bed and giving him saline injections and postural exercises. Please comment on the diagnosis and outline briefly the treatment to follow. Please omit name and address. MD Wisconsin

ANSWER—The history which the correspondent submits of his patient's illness and his examination are quite compatible with the diagnosis of thrombo-angitis obliterans. It is not clear what the correspondent means by the several severe attacks (apparently claudication) which necessitated surgical drainage of the leg. This is an extremely rare complication of thrombo-angitis obliterans. Absolute cessation of smoking tobacco is advisable. It is doubtful whether it is necessary to keep the patient in bed. Good results have been reported by Samuel Silbert (Studies on Thrombo-Angitis Obliterans [Buerger] THE JOURNAL, Sept 17, 1927, p 964) following the intravenous injection of hypertonic salt solution but it is the experience of other investigators that the results are not very impressive. Avoidance of trauma to the feet is important. Great care should be exercised in trimming the nails. The application of medicaments of an irritating nature should be judiciously avoided. The danger of contracting trichophytosis should be recognized and proper treatment should be given if the disease appears. Soft

woolen hose should be worn in cold weather. Postural exercises and contrast baths seem of some value, although it is difficult to evaluate them. The value of artificially induced fever by the intravenous injection of typhoid vaccine has been stressed by N W Barker (Results of Treatment of Thrombo-Angitis Obliterans by Foreign Protein, THE JOURNAL, Sept 19, 1931, p 841).

The most effective method for the treatment of claudication is the use of tissue extracts, as reported by N W Barker, G E Brown and G M Roth (Am J M Sc 189 36 [Jan] 1935), and intermittent negative and positive pressure environment may increase circulation to the extremities, a subject that has been reviewed by E V Allen and G E Brown (Intermittent Pressure and Suction, THE JOURNAL Dec 21, 1935, p 2029).

When the condition of the patient is satisfactory, A W Adson and G E Brown have shown that sympathectomy may be beneficial (Thrombo-Angitis Obliterans, THE JOURNAL, Aug 13, 1932, p 529).

Reviews on the subject of thrombo-angitis obliterans may be found in

- Brown G E Thrombo Angitis Obliterans, Surg Gynec & Obst 58 297 (Feb 15) 1934
Brown G E Allen, E V and Mahorner H R Thrombo Angitis Obliterans Clinical Physiologic and Pathologic Studies Philadelphia W B Saunders Company 1928
Buerger Leo The Circulatory Disturbances of the Extremities Including Gangrene Vasomotor and Trophic Disorders Philadelphia W B Saunders Company 1924
Scupham G W and de Takats Géza Peripheral Vascular Diseases Arch Int Med 58 530 (Sept) 1935

It is impossible to outline in a few words the treatment of thrombo-angitis obliterans which obviously must be varied to meet the various manifestations of the disease.

UNILATERAL EDEMA

To the Editor—The communication in THE JOURNAL January 18 page 238 under Queries and Minor Notes on unilateral edema interests me because I now have under my care a case of unilateral edema for which I have been seeking an explanation. The patient is a woman, aged 81 to whom I was called January 11 on account of symptoms due to pneumonia of the left lower lobe (type II) which had originated five days before I saw her. On the sixth day under my care my attention was called to a marked edema of the right hand extending into the forearm and upper arm to a less degree. The skin was of normal color the joints were flexible there was no pain or tenderness evidence of thrombosis was absent the heart and kidney functions were not such as to explain the condition the fever subsided by lysis respirations varied between 36 and 40 leukocytes numbered 42,900 and the percentage of polymorphonuclears was 92. January 21 an x-ray film showed opacity over the left lung indicating fluid associated with considerable pleural thickening. The heart was displaced far toward the right side. The compression of the right lung accentuated the degree of pathologic changes as viewed in the roentgenograms. There was also marked displacement of the trachea to the right. January 21 following this report the chest was tapped in the tenth left interspace posteriorly and at that point a size 20 self retaining catheter was introduced into the pleural cavity and closed drainage was instituted. At this time edema of the right upper eyelids was noticed. As drainage was not satisfactory only 260 cc being evacuated in about twenty four hours on January 22 another drainage catheter size 22 was placed in the seventh interspace near the lower angle of the scapula and from this drainage appears to be sufficient. With relief of intrathoracic pressure January 23 the edema had disappeared from the arm and hand and from the eyelid. Trying to discover the cause of the unilateral edema (which I do not recall ever to have previously seen except as the result of some obvious pathologic condition) a consideration of the relationship of the great vessels near the base of the heart to the bony chest cage makes it appear likely that an increase in intrathoracic tension together with a lateral displacement of the heart and trachea could easily result in a partial obstruction of the innominate vein of one side by compression between the trachea innominate artery and the first rib resulting in unilateral edema. This appears to me as the most likely cause of the condition in the case under my observation. The prompt disappearance of the edema coincident with relief of tension in the chest cavity would at least seem to indicate some relationship of the edema to the pathologic condition of the chest. I would like to have your opinion of this view. Although my case and that reported in THE JOURNAL are dissimilar in several important respects such as parotitis being a forerunner of the chest conditions and edema in the latter and the occurrence of edema on the side opposite the chest lesions in my case and on the same side in the child with parotitis it is not probable that in both cases the edema was due to compression of an innominate vein?

LINDSAY PETERS M.D. Alameda Calif

ANSWER—The explanation offered of the edema of the right upper extremity and the right upper eyelid in the case described in this communication seems reasonable enough under the circumstances, but obstruction of an innominate vein could not cause the edema of the left leg as described in the query in THE JOURNAL, January 18. Mechanically, edema of the left leg can be caused only by obstruction to the venous return from the leg.

FREQUENT FRACTURES AND FRAGILITAS OSSIUM

To the Editor—I have under my care an otherwise healthy man aged 55 who has sustained several fractures from rather trivial causes. These have all been during the past four years. Healing has been quite satisfactory in each case. Complete studies have been impossible but roentgen examination of the humerus (the site of the last fracture) shows a definitely thin shadow with a thin cortex and rather open trabeculation of the medulla. There are no cystic areas. There is no anemia. General nutrition is excellent and the dietary history average except for rather constant use of alcohol. Serum phosphorus is 3.29 and calcium 9.5 mg per hundred cubic centimeters. The provisional diagnosis is osteomalacia. The patient has been advised to take viosterol 60 drops a day and calcium gluconate 5 Gm a day and foods high in calcium have been recommended. Please advise as to probable diagnosis and comment on the treatment. Does fragilitas ossium ever make its appearance so late in life? Please omit name and locality.

M D, Canada

ANSWER—True fragilitas ossium of the type seen in children does not occur later in life. Decalcification of the skeleton to a sufficient extent to lead to frequent fractures in adults of the age period of the patient are usually due to metastatic lesions, hyperparathyroidism or osteomalacia. Since these fractures have been occurring over a period of four years during which time the patient's health has not been seriously impaired and the fractures themselves have united, malignant conditions would appear to have been ruled out. The relatively normal phosphorus and calcium figures cast a definite doubt on any tentative diagnosis of hyperparathyroidism. There have been several proved cases of adenomas of the parathyroid glands with decalcification of the skeleton and fractures in patients who had a relatively normal content of calcium and phosphorus in the blood. These patients, however, were excreting abnormal amounts of calcium in the urine. It would seem more likely that the patient in question is suffering from the senile type of malacia, which is not necessarily due to excessive excretion of calcium or inadequacy of the diet but to faulty absorption from the intestinal tract. If the patient is suffering from beginning cirrhosis of the liver as a result of the constant use of alcohol, inadequate absorption of calcium might be explained, in part at least, by dysfunction of the biliary system.

The suggestions for treatment that have been outlined are satisfactory. It would be quite safe to double the amount of viosterol and of calcium gluconate by gradually increasing these doses. Although it would be purely empirical, the possibility that the patient is suffering from some degree of liver injury would justify giving some bile salts in addition to the program outlined. Sun baths or ultraviolet treatments may be of value in disturbances of calcium metabolism.

ACIDITY AND ALKALINITY OF STOOLS

To the Editor—Will you kindly inform me in detail how to perform a test for total acidity and total alkalinity of stools. What are the normal figures of total acidity and total alkalinity of stools?

BORIS KAPLAN M D New Bedford Mass

ANSWER—Stools are ordinarily neutral in reaction to litmus paper, although acid and slightly alkaline stools are seen under normal conditions. An acid reaction is less frequent and commonly follows a vegetable diet. The acid reaction is due to the presence of lactic or butyric acid and is indicative of fermentation in the intestinal canal.

In testing the reaction of the stools, litmus is usually employed. Moisten red and blue litmus paper with distilled water and place on a clean glass slide, then rub on a fragment of feces, observing the change of color. Or a small amount of feces is placed in a test tube and a suspension is made in water. A watery solution of tincture of litmus is prepared and a few drops of the fecal suspension added. If the turbidity of the suspension interferes with the reading the suspension may be centrifuged or filtered. Another good test is the use of a 1 per cent alizarin solution. To a drop of this solution on white porcelain add a drop of the feces suspension or filtrate. An alkaline reaction is indicated by a reddish violet to violet neutral no change, and acid a light yellow. The density of the color depends on the amount of acid or alkali present.

A meat diet has a tendency to produce an alkaline reaction. As putrefaction increases alkalinity and fermentation increases acidity the test must be done soon after passage of the stool. Excess of fat increases acidity from the formation of fatty acids. Rapid peristalsis may increase the acidity. Chronic processes as tuberculosis or amebiasis, tend to produce an alkaline reaction. Pancreatic obstruction leads to fatty stools with increased acidity, a block in bile outflow gives an acid stool if there is associated pancreatic disease. If there is no pancreatic disease the stools are usually alkaline.

Thus, the reaction of the stools varies with the diet, motility of the intestinal contents, predominance of putrefaction or fermentation, intestinal disease, biliary or pancreatic obstruction, and other factors. There is no standard method for determining the total acidity or alkalinity of the feces. Extraction of a weighed amount of feces with distilled water, filtration, and titration with tenth normal sodium hydroxide, or acid, will determine the total acidity or alkalinity per hundred grams. Such a method would be similar to that now employed in determining the total acidity of urine.

DISTURBED METABOLISM AND POSSIBLE NARCOLEPSY

To the Editor—A girl aged 17 years well nourished with family and personal history negative except that she has had measles and chicken pox when a child was normal and peppy before she began to menstruate. Since then she has been drowsy rather listless and wants to sleep most of the time. The menstrual functions are normal in every way and physical examination gives negative results. Her progress at school is poor and she does not take a great deal of interest in things about her. I have given her thyroid extract because her eyelids are a little puffy and her facial expression rather suggests that of an acromegaly but the symptoms did not improve. It would seem that the case is one of disturbed metabolism.

E D AUGSPURGER M D Menno S D

ANSWER—The information given in the inquiry is not adequate for a diagnosis. Detailed examination may be necessary. It is probable that the general metabolism is not greatly disturbed, as the patient menstruates normally. The basal metabolism should be determined after administration of thyroid has been discontinued for some time. If the metabolism is low, it should be elevated to normal with thyroid extract, if it is normal, medication with thyroid is inadvisable. If improvement is associated with elevation of the metabolic rate, treatment should be continued under careful control with determinations of the metabolic rate until the maintenance amount of thyroid is determined. If elevation of the metabolism does not cause improvement in symptoms, it is doubtful that this type of treatment need be continued.

The symptoms mentioned may be those occasionally experienced by normal adolescents, may be manifestations of organic intracranial lesions such as tumor or encephalitis, or may be early representations of a psychosis or of numerous organic diseases. If no definite diagnosis, requiring appropriate treatment, can be established, it might be well to try ephedrine sulfate in amounts of 25 to 50 mg three or four times daily (Daniels, L E. Narcolepsy, *Medicine* 13 1 [Feb] 1934) or benzedrine in amounts of from 10 to 40 mg three times daily (Prinzmetal, Myron, and Bloomberg, Wilfred. The Use of Benzedrine for the Treatment of Narcolepsy, *THE JOURNAL* Dec 21, 1935, p 2051). It is supposed that the patient has adequate sleep and outdoor recreation.

EPILEPSY

To the Editor—I have under my care a white girl aged 13 years who a day or two prior to the onset of her menses has a seizure consisting of unconsciousness, defenseless falling, pallor and muscular rigidity. The attack lasts two or three minutes with no after-effects. The menses began at 11 and occur regularly every twenty six to thirty four days. Physical examination is negative. Laboratory tests are negative except for a slight secondary anemia. Her past history is negative and there is no familial history of epilepsy. Several times in the past she has had nocturnal enuresis the night before her menstrual onset. I attribute this to nocturnal attacks of epilepsy. She is an active girl, I attribute this to nocturnal attacks of epilepsy. She is an active girl, I attribute this to nocturnal attacks of epilepsy. My present treatment consists of general hygienic care, iron and ammonium citrate, a high fat diet and 15 grain (1 Gm.) doses of bromides three times daily. This has lessened the severity of the attacks but has not reduced the number. I would appreciate any suggestions as to treatment. Do you feel that bromide or phenobarbital medication the week prior to the onset of the menses would be more desirable? Please omit name.

M D Ohio

ANSWER—The attacks described suggest short grand mal seizures of essential epilepsy. It is assumed that the first seizures began with the menses at 11. In the treatment it would be advisable to use the high fat diet according to the directions of the introducer, that is, be sure that the carbohydrate allowance does not exceed 15 Gm daily, the protein 1 Gm per kilogram of body weight and the fat in increasing amounts as much as necessary or as can be tolerated, to produce ketosis. The fluids should be restricted to 1,000 cc daily. If medication becomes necessary after the ketogenic diet has been given a trial, phenobarbital is much more desirable than the bromides. It should be given for one week preceding the menses in doses of 0.03 Gm three times a day, increased to 0.05 Gm if necessary.

DEMINERALIZATION AFTER FRACTURE

To the Editor—On Jan 29, 1936, a woman aged 50 sustained a fracture of the right wrist. Roentgen examination the same day revealed a Colles' fracture with only a slight displacement of the fragments. Next day under an anesthetic the fracture was reduced and put in a sugar tong splint. Later roentgen examination revealed good reduction and fragments in good position. The patient was advised to use her fingers and to abduct the arm a number of times a day. She got along nicely for two and one-half weeks without pain or difficulty. I was called one day for pain in the elbow. Thinking that the splint had slipped I removed it, cut it down at the elbow and replaced it. The patient thought it was too loose but I told her to let me know the next day and I would tighten it. Next day she called me her hand had swollen considerably and so I removed the cast again and adjusted it. I advised massage and bathing in hot salt solution. I took a third roentgenogram a few days later and found nothing wrong with the fracture. The position was good. Since that time I have removed the cast entirely and advised massage, heat treatment and soaking in hot salt solutions. To date the swelling has persisted in the hand, the fingers are markedly swollen and she cannot use the hand in either adduction or abduction without considerable pain. She cannot bend the little and ring fingers at all. Can you advise me what has happened in this case and what is to be done? There seems to be pain in the shoulder also which she did not have for about three weeks. I have no galvanic or faradic current. Please let me know at once. Kindly omit name and address. M D New York.

ANSWER.—The inquirer should have noted the mineral content of the bone of the hand, wrist and shoulder. This may be a case of demineralization following trauma (a very common lesion). There may be a neurocirculatory aspect producing an osteoporotic lesion. There may be an element of causalgia in this case.

A splint and active movements should be tried. Heat often exaggerates this type of pain. Electricity may do likewise. Massage by the patient using her other hand may do more good than physical therapy by a trained person.

With regard to calcium balance there may be a glandular element, owing to the age of the patient, who is in the climacteric phase. Calcium gluconate plus a high calcium diet may be of value.

Concerning the shoulder, it is well known that as a result of concussion followed by hemorrhage and adhesions which occur in the shoulder, following a fracture of the wrist, a traumatic arthritis may supervene.

LOW BACK PAIN AND POSTURE

To the Editor—I am treating a married woman aged 22 who has been complaining of low back pain and frequency of urination for the past four months. Physical examination shows only an exaggerated lumbar curvature (anteroposterior) of the spine. There is also a slight degree of round shoulders. Pelvic examination is negative as are repeated urinary examinations. Would the lordosis be sufficient reason for the symptoms? If so what treatment can be suggested. Please omit name. M D New York.

ANSWER.—Low back pain, in the absence of any organic disease, is not infrequently due to chronic faulty posture. In the case described it would be significant to determine by x-rays whether or not the primary anteroposterior curve is that of the dorsal spine as suggested by the round shoulders or of the lumbar spine. Anterior wedging of the dorsal vertebral bodies and a rigid rounding of the back are commonly caused by changes described as vertebral epiphysitis. The forces of gravity require a compensatory lordosis of the lumbar spine to keep the body weight in balance. This causes a more acute angle between the fifth lumbar vertebra and the sacrum. The weight that should be borne squarely on the fifth lumbar vertebral body and transmitted through this body to the sacrum is therefore shifted backward to the small lateral articulations. These articulations are not adequate to carry this weight load and hence pain may be expected.

Treatment for backache of the type that has been described consists of an attempt to correct the mechanics of the spine. This calls for a program of physical therapy. Exercises are given that will tend to correct both the dorsum rotundum and the pelvic tilt and thus relieve the strain at the lumbosacral angle. Such exercises can be safely taken only in the recumbent position and include head and shoulder raising while lying both face downward and on the back. Exercises of this type will tend to straighten the dorsal spine and to strengthen the abdominal muscles. Assuming the knee chest position tends to flatten the lumbar spine and further correct the pelvic tilt and the lumbosacral angle. Exercises are indicated also for stretching the iliobial band and the flexors of the thighs, both of which become shortened secondary to the chronic downward tilt of the front of the pelvis.

A well reinforced corset or brace should be worn that will help to support the abdominal muscles and correct the pelvic tilt. Shoulder straps attached to the brace remind the patient

to stand straight with shoulders back. If this type of program is followed, relief from pain and functional recovery for the average patient can be expected.

INTRACTABLE INSOMNIA

To the Editor—Intractable insomnia in a patient of mine a section foreman aged 51 puzzles me greatly as to its cause and management. Physical examination shows all systems of the body apparently normal. His weight is 166 pounds (75 kg), height 5 feet 5 inches (165 cm) and blood pressure 120 systolic 80 diastolic. His father died of cancer and his mother died of apoplexy and there is no history of insanity anywhere in his ancestry. One brother and three sisters are all in good health. He had typhoid at the age of 15 and appendicitis fourteen years later but no other illnesses or complaints until eleven years ago when he was unable to sleep for ten days. Now he has not had three nights sleep with or without sedatives for three weeks. 0.3 Gm. of amylal one night gave him no sleep and 0.5 Gm. the following night resulted in one hour of sleep and he was taking regular doses of bromides besides. Please state whether you think he might be helped by properly directed psychotherapy or if he may improve under medical management, and outline course. Please omit name. M D Washington.

ANSWER.—In a man of 51, intractable insomnia may occur from many organic conditions, particularly of the central nervous system. Cerebral arteriosclerosis without hypertension, is one of the more common causes, examination of the peripheral, and more especially the retinal, arteries may help in the diagnosis. The family history of apoplexy should also be considered in this light. Brain tumor and neurosyphilis call for special investigation of the retinal fundi, blood and cerebrospinal fluid.

The majority of cases of insomnia, especially of the intractable, periodic type, have a psychogenic origin. In many instances, however, the physician is taxed to his utmost to find the cause. Simple anxieties and worries usually have their basis in fear—fear of poverty, of ill health, of unworthiness or of domestic insecurity. In men of 50, cancer of the prostate, angina or 'shock' are the principal causes of anxiety regarding health.

It must not be forgotten, moreover, that insomnia is a frequent symptom of mental disease, particularly in the manic-depressive states. Mild manic phases, periodic in character and often not associated with depressions, are most often evidenced by insomnia. This perhaps the most frequent cause of all, is also least often thought of by physicians. In such instances the normal sleep rhythm may be resumed in a few weeks. A patient passing through a period of insomnia, unless it is of very brief duration, needs and should receive the appropriate sedatives. Sleep thus brought about may cut short a more severe mental illness.

BLOOD CHOLESTEROL DETERMINATIONS AND BASAL METABOLIC RATES

To the Editor—What reaction does the blood cholesterol level have to the basal metabolic rate in children? Can this determination be used in ascertaining hypothyroid and hyperthyroid states without requiring the use of a metabolism machine? The reports in the literature to date discredit the use of this blood test in determining altered thyroid states in adults.

EDWARD SUCKLE, M D Coatesville Pa.

ANSWER.—Determination of the total blood cholesterol is of definite value in corroborating the diagnosis of hypothyroidism in children just as it is in adults. It is of no special value in the diagnosis of hyperthyroidism in children or adults except that hyperthyroidism is not likely to be present if the total blood cholesterol is over 200 mg per hundred cubic centimeters. Reports that tend to discredit the value of the blood cholesterol in the diagnosis of myxedema refer to hypothyroidism, a term confused with hypometabolism. Primary thyroid deficiency gives rise to myxedema even though the individual may not present all the clinical features of the disease. Total thyroidectomy is followed by myxedema and hypercholesterolemia even in a few cases in which the basal metabolic rate does not drop significantly. Hypercholesterolemia may be due to other causes, some of which may not always be ascertained. If there is a suspicion of myxedema in these cases, a therapeutic trial of desiccated thyroid is as justified as when a low metabolic rate is found. There are more low metabolisms found which are unassociated with thyroid deficiency than there are with thyroid deficiency. Myxedema is still a comparatively rare disease.

Since basal metabolic rates are difficult to obtain in children, and since the standards for calculating the basal metabolic rate in children are far from satisfactory, a high blood cholesterol in a child, along with some clinical evidence of thyroid deficiency (bone, age, skin, mental reaction) is as reliable as any laboratory procedure.

Various methods of determining blood cholesterol do not give consistent results, so that it is important to know the normal range by any given method.

Nebraska June Examination

Mrs Clark Perkins, director, Bureau of Examining Board, reports the written examination held in Omaha, June 9 10, 1936 The examination covered 10 subjects and included 88 questions. An average of 75 per cent was required to pass. Seventy-three candidates were examined, all of whom passed. The following schools were represented

| School | PASSED | Year Grad. | Number Passed |

North Dakota July Report

Dr G M Williamson, secretary, North Dakota State Board of Medical Examiners, reports the oral and written examination held in Grand Forks, July 7-10, 1936. The examination covered 13 subjects and included 100 questions. Eight candidates were examined, all of whom passed. One physician was licensed by reciprocity and 2 physicians were licensed by endorsement. The following schools were represented

Book Notices

Diagnostic Roentgenology Edited by Ross Golden, M.D., Professor of Radiology, the College of Physicians and Surgeons, Columbia University. Fabrikoid. Price \$20. Pp. 864 with 964 illustrations. New York & Edinburgh: Thomas Nelson & Sons, 1936.

This volume is a noteworthy American contribution. The authors of the various chapters have been carefully selected, so that the book represents a consensus on diagnostic roentgenology. In his introduction, Dr. Golden states that the information obtained from a roentgen examination, even when it points clearly to a definite pathologic diagnosis, must be correlated with the history, the physical examination and the laboratory observations. This can best be accomplished by the cooperation of the clinician and the radiologist. The former must not expect his clinical impression always to be confirmed and must be prepared at times to discard certain preconceived ideas with regard to a case, the latter, while considering the clinical evidence and "what ought to be there," must at the same time keep an objective and unbiased point of view to avoid overlooking something unsuspected by the clinician. Even when a positive diagnosis cannot be made, information of great aid may be obtained. The importance of cordial sympathetic cooperation of clinician and roentgenologist and frank discussion of specific clinical problems cannot be overemphasized.

Allen O. Whipple, in the foreword, points out that no single diagnostic measure has so profoundly altered the diagnosis and rationale of the therapy of diseases requiring surgery as has the discovery of Roentgen with its subsequent developments. The roentgenologist should be as well trained in the fundamentals of medical science as the physician or surgeon and should have a real experience in clinical medicine as intern and resident. Without this training he cannot discuss the patient intelligently with his associate clinicians.

In the foreword also W. W. Herrick states that, while it may be debated whether the best results for the patient and for the science of roentgenology may not follow limiting its practice to the specialist, the advantages of having all factors in diagnosis, including the roentgenologic, under the immediate control of the clinician, with the continuity of observation and the saving of time thus brought about, cannot be denied. The increasing tendency for the clinician to make and interpret his own roentgenograms may lead to an exaggeration of the importance of the method and to direct error.

Chapter I, by Cornelius G. Dyke, concerns the roentgen diagnosis of diseases of the skull and intracranial contents. The roentgenologic criteria for the diagnosis and treatment of cranial and intracranial lesions have been set forth as briefly as is commensurate with accuracy. Chapter II, on the roentgen examination of the paranasal sinuses and the mastoids, is by G. W. Grier. The description of the positioning of the patient to be roentgenographed is good although it is felt that sketches illustrating graphically the relation of the central ray, the angle of the skull and the position of the film would be clearer. The author fails to mention the Rheser position, which frequently gives differential evidence in the anterior and posterior ethmoidal cells, and also the Stenvers position for demonstrating the petrous tip cells, which is the reverse of the Granger position, the petrous being projected through the temporal bone.

Chapter III, by Coleman B. Rabin, is on the radiology of the chest. A brief description of atelectasis and emphysema is followed by an excellent discussion of the pneumonias and the various forms of pulmonary tuberculosis. After short discussions of the unusual infections of the lungs (fungus diseases, psittacosis, echinococcosis) only one page is devoted to pneumococcosis. There are fifteen pages on primary and metastatic lung tumors, and thirty pages on diseases of the pleura, diaphragm and mediastinum.

Chapter IV, on the clinical roentgenology of the cardiovascular system is by Hugo Roesler. This sixty-seven page chapter contains an excellent discussion of the roentgen examination in the various diseases of the heart and aorta. The introduction includes a discussion of the technic of fluoroscopy and orthodiagraphy, cinematography and kymography. The

anatomy and measurements of the cardiovascular system cover seventeen pages. The clinical considerations are divided into (1) dilatation, (2) appearances from the standpoint of etiology, (3) structural changes, (4) widening, elongation and increased density of the aortic shadow, (5) diseases of the pulmonary artery, (6) pericardial disease and (7) congenital cardiovascular malformations. This chapter, for its size, is one of the best discussions of the value of roentgenology in cardiovascular disease that has appeared in English.

Chapter V, on the roentgen examination of the digestive tract, by Ross Golden, covers eighty-six pages and includes discussions on the esophagus, stomach, duodenum, jejunum and ileum, large intestine and gallbladder. The correlation of the roentgen and pathologic examinations is commendable.

Chapter VI, on the roentgen diagnosis of diseases of bones, is by Paul C. Hodges, D. B. Phemister and Alexander Brunschwig, and the editor could have chosen no better qualified group. The discussion deals with diseases of bones and joints but does not include consideration of fractures, dislocations or postparalytic deformities and the operative procedures calculated to correct them. In this chapter discussion of the normal has been made brief, partly because of space limitation, partly because excellent atlases of the normal are available in the English language. The chapter includes the roentgen appearance of the normal skeleton, the skeleton of the child, generalized alteration in bone density, congenital anomalies of skeletal development, infections and parasitic involvement of the bones, bone changes in endocrine disturbances, bone changes due to metabolic disturbances, aseptic necrosing lesions of bone, chronic arthritis, abnormal deposition of bone calcium in soft tissue, bone changes produced by certain physical and chemical agents, neuropathic lesions of bones and joints, pulmonary osteoarthropathy, melorheostosis, bone and joint changes in hemophilia, xanthomatosis of bones, bone changes associated with congenital arteriovenous aneurysm, congenital varicosities in the extremities, bone changes in neurofibromatosis, Paget's disease of bone, osteitis fibrosa cystica, multiple fibrocystic disease, hyperparathyroidism and bone tumors. The excellent charts of Camp and Cilley on the normal development of roentgenologically important bones and epiphyses and by Paul Hodges on the development of the human skeleton are reproduced.

Chapter VII, on the roentgen diagnosis of spinal cord tumors by Cornelius G. Dyke, is a most valuable one because this is a new and important field. The chapter includes roentgen signs of intramedullary, extramedullary and extradural types of tumors. The section on the use of iodized oil includes technic and interpretation. The comparatively new work of the measurements between the pedicles, known as the interpediculate distance, by Elsberg and Dyke is commendable. A chart is included showing the extreme and usual interpediculate measurements of each vertebra in millimeters, from the second cervical to the fifth lumbar inclusive. The recognition of intraspinal neoplasms by means of roentgenograms is based, mostly, on a thorough knowledge of the size and shape of the spinal canal and the appearance of the individual parts of the vertebrae. Contrary to the accepted belief it is frequently possible to determine the character of the growth, and whether it is extramedullary or extradural, from the roentgenograms. Neoplasms of the spinal cord and its coverings and also of the nerve roots, unlike intracranial tumors, do not produce a generalized reaction on the vertebrae which can be seen in the roentgenograms. However, they often provoke changes in the contiguous vertebrae and may alter the surrounding soft tissues over a limited area corresponding to the site of the growth. The factors on which a diagnosis is based are (1) bone destruction, (2) appearance of and measurement between the pedicles, (3) distortion of the paraspinal tissues, (4) bone proliferation, (5) abnormalities of the intervertebral disks, (6) kyphosis and scoliosis, and (7) calcification. The first three are the most important.

Chapter VIII, on the roentgenologic diagnosis of diseases of the urinary tract, is by Leopold Jaches and Marcy L. Sussman. The subject of urography has been covered thoroughly in spite of the relative compactness of the section. Especially to be commended is the chapter on intravenous urography, which presents an excellent analysis of the indications, contraindications

tions and technic of this invaluable diagnostic procedure. The illustrations include all the common and many of the unusual urologic conditions that may be demonstrated by roentgenography. No mention of the danger of embolism is made in the paragraph devoted to air cystography. It is not a procedure to be adopted as a routine without recognition of this possibility.

Chapter IX, on uterotubography, is by Samuel A. Robins and Albert A. Shapira. The authors' technic is described and their results are evaluated. A good description of the use of uterotubography in cases of sterility is included, which undoubtedly is its most practical application. The authors' conclusions with regard to the diagnosis of pelvic tumors may be questioned. Their final statement "that the combination of pneumoperitoneum with hysterosalpingography ought to give better results" implies lack of experience with their combination method. The appended bibliography, however, includes references on that subject.

Chapter X is on the use of the roentgen rays in obstetrics, by Howard C. Moloy and Paul C. Swenson. The portion dealing with pelvimetry and pelviradiography is well prepared, profusely illustrated and adequately described. The parts, however, dealing with the purely clinical considerations of obstetric radiography are less complete and the illustrations are poorly reproduced. Drawings or diagrams would be more useful in a book used for reference than prints which do not reproduce clearly what may be seen in films when viewed in a shadow box. It is to be regretted that the authors did not elaborate more fully on the roentgen diagnosis of monstrosities and multiple pregnancy, as it has been emphasized repeatedly in the literature that therein lies its chief value. Triplets and even quadruplets have been diagnosed by means of roentgenography, and many cases of hydrocephalus and anencephalus have been reported with satisfactory roentgenographic reproductions.

Chapter XI, on the radiology of fractures, by Edward H. Skinner, is valuable to the radiologist, orthopedic surgeon and industrial surgeon. From the medicolegal point of view every physician and surgeon should read this chapter. The author has fortunately reproduced diagrams illustrating his diagnostic lines, such as the Shenton-Skinner line at the hip, and Skinner's lines at the wrist, elbow and ankle.

Basic knowledge of osseous anatomy, ossification and congenital variations serve to promote correct roentgen interpretations. The textural detail of certain spongy bones demands excellent negatives to note compression of the trabeculations where there is minimal change in the external contours of the bone, for example, vertebral bodies, lower end of the radius, astragalus, os calcis, scaphoid and os magnum. The normal joint contours, the weight-bearing lines of such joints and the advantageous atypical exposure angles become necessary elements in the radiographic examination of joints that fail to present an obvious and undeniable fracture line. The wrist, ankle and elbow are the principal joints that demand such meticulous attention, likewise they are the ones most frequently fractured. Better technical films of bones through plaster casts are made with very low kilovoltage (from 45 to 55), with low milliamperage (from 5 to 10), with double screens and long exposures (from ten to thirty seconds) and at increased distances (36 inches). The use of a Lysholm grid becomes invaluable in roentgenography of bed patients.

Ninth Annual Report of the Giza Memorial Ophthalmic Laboratory, Cairo 1934. Ministry of the Interior Department of Public Health. Paper. Price 25 P. T. Pp 150 with illustrations. Cairo: Schindler's Press, 1935.

This is divided into an administrative and a professional report. The former is completely but concisely stated. The professional report is considered under four subsections: postgraduate education, pathologic, clinical and research sections. In the postgraduate school a high standard of proficiency is maintained in both clinical and surgical practice, as attested by the fact that only twenty of thirty-five candidates were successful in the examinations for appointment in the government ophthalmic service of Egypt. During the year 571 pathologic specimens were submitted to the laboratory for examination, among which were 158 excised globes. Fifteen of the most interesting pathologic specimens have a not too lengthy but adequate description. This section is well illustrated. The staff

was freely used in a consultative capacity. The cases studied were most interesting and instructive. Five of the cases are detailed, and three colored plates in this section afford a pleasant surprise. The research section is subdivided into pathologic and bacteriologic research and clinical and therapeutic research. It is only natural that the major part of this work is devoted to phases of trachoma and the ophthalmias. The work is of high order and the conclusions drawn are conservative and justified. This year, as in past years, the clinical material was made available to a nonresident staff member for experimental purposes. The invited guest was Dr. Gardilic of Zagreb. He spent four months employing his method of applying "Arolid" to trachomatous lids. In the opinion of the staff of the Memorial Ophthalmic Laboratory, the results secured were unsatisfactory. The report is well arranged, well illustrated, interesting and instructive. It is worthy of thorough study not only by those who have to deal with reports but, because of its clinical value, by all ophthalmologists.

The Art of Public Health Nursing. By Edith S. Bryan, M.A., Ph.D., R.N. Chairman, Northern Branch of California League of Nursing Education. With an introduction by Elnora E. Thomson, R.N., Professor of Nursing, University of Oregon Medical School. Cloth. Price \$2. Pp 296. Philadelphia & London: W. B. Saunders Company, 1935.

This is a good reference book for more mature nurses who have had considerable experience in hospital or public health nursing work but who lack the art of discussing or writing about their work. The author puts little, if any, stress on good nursing care of the sick in their own homes. This is fundamental if one is to teach the well successfully, and undoubtedly Dr. Bryan believes that all public health nurses appreciate this fact. Nurses are not teachers until by maturity, experience and study they have gained an ability to share their useful knowledge with others who lack it, and, in putting so much emphasis on teaching, the author may have forgotten that she was writing primarily for nurses. In its emphasis on the dignity of human personality latent in every patient, the book makes its most valuable contribution to literature for nurses and friends of nursing. On many pages are dogmatic statements that may be questioned. The book is simple and helpful reading for the initiated, it is difficult reading for beginners who are not able to challenge its "musts" and many other positive statements. It is well worth its modest price and deserves a place in every book collection that aims to better public health nursing or to explain the work to people who may be responsible for the preparation of nurses who will enter homes as public health nurses, whether they give care to the sick or endeavor to teach personal and community hygiene and good health.

The Comparison Between the Visual Results Obtained by Various Methods Employed for the Treatment of Concomitant Strabismus. By T. Ab Travers. An essay for the Gifford Endowment Prize in Ophthalmology. Printed and published for The British Journal of Ophthalmology. Paper. Pp 127 with 21 illustrations. London: George Paulman & Sons, Ltd., 1936.

This booklet is a frank discussion of the modern methods of handling concomitant strabismus, based on an extensive experience by the author and a careful digest of the literature. In turn are dissected each of the four elements involved in such treatment, namely, the optical treatment, that of amblyopia, orthoptic training, and finally surgical intervention. Great emphasis is laid on retinal correspondence and the simpler methods of measuring that function. However, it is certain that there is no universal agreement with his statement that "abnormal retinal correspondence is a very common condition, occurring in 50-60 per cent of all cases of squint." Unfortunately some of his conclusions seem to be based on the blind acceptance of that statement. There is a full discussion of amblyopia together with suppression fields for which the author has developed an ingenious new technic. But the question as to whether the amblyopia is of central or peripheral origin is left open. In the matter of fusion, the author seems to adhere to the modified Worth dictates and concludes that "fusion training can improve a function already present but cannot usually develop the function." He also adds most properly that fusion training alone is likely to prove insufficient in squints of more than 20 degrees. Unfortunately, his results must be discounted because training was not attempted when the vision in the worse eye was less than 6/12 with correction. His surgical indica-

tions are sound and it is most gratifying to note the statement that "in all probability there is not a great deal to choose between the various methods [of operation]. The surgeon's skill and judgment are the most important factors in the result—not the method." The last thirty pages are devoted to tables, which goes to show that anything one wishes can be proved by statistics. But it is a good piece of work, well conceived and honestly done. The problem of concomitant strabismus is set forth clearly and simply without confusing cross arguments and the author shows the results he obtained in certain classes of cases with certain methods. It can be read profitably by all ophthalmologists and pediatricians.

The Doctor By Mary Roberta Rinehart Cloth Price \$2 Pp 500
New York & Toronto Farrar & Rinehart Inc 1936

Mrs Rinehart's ability to tell a story needs no encomium in these columns. She is a past master in the art of novel writing, and a long shelf of successful volumes attests her ability. Many of her stories deal with the atmosphere of the hospital and the medical profession, a reflection of her training as a nurse. The story of "K" is widely known as one of her most successful contributions. The present novel deals with a physician, with his devotion to his profession, with his admiration for the daughter of a rich manufacturer and political boss who lives on the hill, with his marriage to the daughter of his housekeeper, a response to his innate acceptance of responsibility for the sick and the needy. It describes his reaction to the usual epidemic of typhoid. As may have been expected, the wife of his first marriage fails completely in meeting her responsibilities, either to him or to his profession. Eventually an unnecessary motor accident deprives him of the use of one of his hands, and the latter portion of the novel is concerned with his gradual recovery and his final romance. Mrs Rinehart, it becomes clear, recognizes the individual character of the physician's work, the nature of the practice of the family doctor, and the hopelessness of the mechanized method as a solution for the medical problem. Her novel will take its place as one of the best fictional contributions in the field of medicine.

Les avortements mortels Par H Mondor professeur agrégé à la Faculté de médecine de Paris Paper Price 65 francs Pp 445 with 43 Illustrations. Paris Masson & Cie 1936

This book is in reality an encyclopedia of all the possible harmful effects that may result from abortions. It is based on a study of the world literature and the author's extensive experience with cases of abortion. The book is divided into twenty-seven chapters. Some of the important ones deal with the following aspects of fatal abortion: sudden death, especially that due to embolus, traumatic perforation of the uterus, intra-uterine instillations, infarction and necrosis of the uterus, gangrene of the uterus, abscess of the uterus, postabortal peritonitis, internal hemorrhage, septicemia postabortal tetanus attempts to produce abortion in the presence of an ectopic gestation and attempts to empty the uterus in women who are not pregnant. The book is well illustrated with material chiefly from the author's own cases. Numerous case histories are cited and most of these likewise are from Mondor's own experience. The book does not lend itself to a critical review because it is a volume of facts. However, special mention must be made of the considerable amount of space devoted to the treatment of each complication discussed. The author is to be commended most highly for this monumental work which is an invaluable reference book on the subject of fatal abortion.

Proposed The University of the United States By Edgar Bruce Wesley Associate Professor of Education University of Minnesota With an Introduction by Lotus D Coffman President of the University of Minnesota Paper Price 75 cents Pp 83 Minneapolis University of Minnesota Press 1936

The idea of a national university seems to have been current at the time of the Revolutionary War. Samuel Blodgett claims to have suggested it to Washington in 1775. The earliest detailed proposal on record however is that of Dr Benjamin Rush who in January 1787 on the eve of the constitutional convention, issued an "Address to the People of the United States" in which he urged the establishment of a federal university designed to prepare the citizens for the responsibilities of government. From that day to this, at intervals long or short, the conception has been revived, but, in the words of

the author, "nothing has ever been done about it," from which it may be inferred that the people either disapprove or are indifferent to the project. The second part of the book presents tentatively a plan of organization and administration for the proposed university if and when it is to be established.

High Wall By Alan R Clark Cloth Price \$2 Pp 280 New York Harrison Smith & Robert Haas 1936

This is a typical mystery story concerning the inmates of a sanatorium for psychiatric patients. The author has been able to maintain the atmosphere of the institution, to indicate the nature of the mental disturbances and to maintain at the same time the kind of intense interest that should be associated with a successful mystery story. The book is blunt and direct and much more real than esoteric. As a mystery story with a medical interest, it is more than worthy of medical attention.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Twin Pregnancy, Rupture of Uterus, Failure of Diagnosis—One of the defendants, Dr Anne West, was employed to care for Mrs Vergie Edwards during pregnancy and childbirth. In the course of her attendance she said several times that she thought that Mrs Edwards would have twins, and while labor was in progress the same possibility was talked of by some of Mrs Edwards' neighbors, apparently in Dr West's presence, if not with her participation. Labor came on about 6 p. m., February 7, and lasted until 7 o'clock the next morning, when a baby was born, at term. The account of the labor, published in the opinion of the appellate court, is meager. The presentation of the child is not stated. There was testimony concerning symptoms of a ruptured uterus, excessive loss of blood and paleness, and it was made to appear that the afterbirth had more "blood and stuff" in it than the afterbirths that had followed the deliveries of Mrs Edwards previous children, but there was nothing to show that the possibility of a rupture of the uterus was considered or acted on during delivery. In denying a rehearing, the court commented on the fact that Dr West had "pressed on" her patient over the womb, possibly intending to imply that that had something to do with the rupture of the uterus that was discovered later, but the decision of the court says that there was no testimony tending to account in any way for the rupture.

Immediately after the baby was born a large mass or knot was seen in the upper part of the abdomen, which in the next few hours found its way to the lower left side of the abdominal cavity. Although Dr West knew that Mrs Edwards' left ovary had been removed several years before, she concluded that this mass was an ovarian tumor. During the night following the delivery, Dr West concluded that Mrs Edwards was suffering from "locked bowels" and ordered an enema. Two days later she took her patient for diagnosis and treatment to the West Texas Hospital, at Lubbock, twenty-two miles distant. There Mrs Edwards seems to have been under the joint care of Dr West and of Dr C. J. Wagner of the hospital staff. Neither Dr West nor Dr Wagner used the x-ray apparatus present in the hospital, but apparently they diagnosed Mrs Edwards' trouble as inflammation, tumor and locked bowels, and sedatives were administered, enemas given, and hot packs applied to the abdomen to reduce the swelling. Mrs Edwards' condition did not improve and after eleven days she was returned to her home in Dr West's care with instructions from Dr Wagner to continue the treatment that had been used in the hospital. About one week later, March 3, she was taken to the Lubbock Sanitarium. It was realized there that an immediate operation was desirable but because of the patient's condition action was postponed until the following day. At the operation more than a gallon of pus and other fluid was withdrawn from the abdominal cavity, and then

a badly decomposed fetus was found one that apparently had been fully developed and ready for delivery, February 6 when its twin sister was born. The uterus had ruptured. There was no evidence of an ectopic pregnancy. Mrs. Edwards died March 11, about one month after the delivery of the first twin.

Mrs. Edwards' husband, her minor children and her mother sued Dr. West, the West Texas Hospital and Dr. Wagner, alleging negligence on the part of each of them. The trial court directed a verdict in favor of the defendants, and the plaintiffs thereupon appealed to the court of civil appeals, Amarillo. They alleged that the directing of a verdict by the trial court was error, because the evidence raised the issue of the defendants' negligence in failing to make a proper diagnosis and prescribe proper treatment. The appellate court reversed the judgment of the trial court and remanded the case for a new trial.

The defendant West Texas Hospital contended that it had in no manner attempted to interfere with or participate in the diagnosis and treatment of the case and that it undertook only to render such facilities and services for patients as are customarily furnished by hospitals to physicians with respect to patients in the institution. It contended that the owner of a hospital—whether an individual, firm or corporation—is not liable for damages for injuries resulting from negligence in diagnosis or treatment in the institution by physicians employed by the patient or any one other than the hospital. But the appellate court pointed out that the stationery used by the defendant hospital contained a list of the names of the hospital staff and that the name of Dr. Wagner, who treated Mrs. Edwards, headed the list. The business manager of the hospital, too, had referred financial matters to Dr. Wagner and had demanded from Mrs. Edwards' husband a note to cover Dr. Wagner's fees before he would consent to her leaving the hospital. It is not clear, said the court, why the manager of the hospital should in effect assert that the hospital had a pledgee's lien on the person of Mrs. Edwards and would hold her in pawn until "our doctor's fees are paid," if Dr. Wagner and the hospital were acting independently. The common use by Dr. Wagner and the business manager of the hospital of the pronoun "we" in discussing what would and would not be done tended to show a business connection between Dr. Wagner and the hospital. Moreover, if a partnership relation existed between Dr. Wagner and the hospital, or if he was the hospital's agent the hospital might be liable for damages for such negligence, if any, as might be proved against him. Although there was a sworn denial of partnership, the court thought the evidence sufficient to require the trial court to submit the issue to the jury. Parties, said the appellate court, may be bound as partners as to third parties, even in the absence of a partnership agreement.

Dr. West admitted that Mrs. Edwards had informed her that she had been operated on for an ovarian tumor several years before coming under her care, and that she nevertheless diagnosed Mrs. Edwards' trouble as an ovarian tumor. She did not know that a fetus remained in the abdominal cavity. She claimed that she had used ordinary skill, care, prudence and diligence in ascertaining Mrs. Edwards' condition and in having her brought to the West Texas Hospital for diagnosis and treatment by its physicians and nurses and in particular by Dr. Wagner. Dr. Wagner contended that he made a physical examination of Mrs. Edwards using all means which in his opinion and best judgment as a physician and surgeon were necessary to ascertain her ailment. He claimed to have diagnosed her case but what his diagnosis was he did not state. He did not believe an immediate operation was necessary and did believe that an operation either would result in Mrs. Edwards' death or would endanger her life. Neither Dr. West nor Dr. Wagner offered any explanation of their failure to use the facilities for an x-ray examination that were available in the hospital.

The defendant physicians and hospital sought to justify the trial court in its directing a verdict by pointing out that there was no testimony from any physician or surgeon or other witness qualified to testify as an expert that any act was done, or that there was any failure to do any act, from which act or omission the jury might infer negligence on the part of the defendants. The appellate court, however, refused to sub-

scribe to the doctrine that the issue of negligence is one that only experts can determine and that proof of bad results is no proof of negligence in any case. Moreover, the court pointed out that two physicians testified that x-rays would have shown that the supposed tumor was a fetus. Whether the failure of the defendants to use x-rays was or was not negligence was a question for the jury to decide. When Mrs. Edwards was operated on at the Lubbock Sanitarium there was nothing to show that the fetus then removed was the product of an ectopic pregnancy, one that had occurred outside the uterus. On the other hand, there was a rent in the wall of the uterus through which the fetus had passed from the uterus into the abdomen. From these facts the jury might have concluded that the defendants had failed to sustain their contention of the existence of coincident intra-uterine and extra-uterine pregnancies. Moreover, in the opinion of the court, the facts that after the delivery of the first child there was a swelling in the upper part of the abdomen, which a few hours later was lower down in or near the pelvic cavity, was inconsistent with the defendants' diagnosis of ovarian tumor, and from those facts the jury might have inferred negligence. The determination as to whether the degree of care and skill used is or is not such as to constitute negligence said the court, is the prerogative of the jury. The court below erred, in the opinion of the appellate court, in directing a verdict for the defendants—*Edwards v West Texas Hospital (Texas) 89 S W (2d) 801*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Amoebiasis and Bacillary Dysentery in Los Angeles County Hospital, 1929-1935—Kessel and his associates point out that in southern California both bacillary and amoebic infections are endemic and that there occur a variety of gastrointestinal symptoms associated with them, which range from a mild diarrhea to acute or chronic dysentery. On the basis of their investigations, the authors reach the following conclusions: 1 Dysentery in southern California is caused primarily by three types of micro-organisms, *Shigella* paradyenteriae and *Salmonella* morganii, together with several other species of *Salmonella* and *Endamoeba histolytica*. 2 Acute bacillary dysentery is encountered much more frequently than acute amoebic dysentery. These two types may often be differentiated by microscopic examination of the stool the bacterial type usually showing a prolific cellular exudate with a preponderance of polymorphonuclear leukocytes and the amoebic type showing a scanty exudate made up almost entirely of macrophage cells in addition to the trophozoites of amoebas. 3 Chronic amoebiasis is proportionately more common than chronic bacillary dysentery. The latter however, occurs more frequently than many think and should be suspected as being associated with *Shigella* or *Salmonella* rather than with *Bacterium streptococcus*. 4 Carriers of *Endamoeba histolytica*, *Shigella* and *Salmonella* have been observed the bacterial types being somewhat less common than the amoebic. 5 Recently an outbreak of bacillary dysentery occurred which was caused by the *Shigella* paradyenteriae Sonne. 6 Although the agglutination reactions are diagnostic the lactose fermentation is much slower and less regular in occurrence than such reactions commonly reported for 'Sonne' and also less regular than those produced by five other strains of Sonne with which they were compared. 7 Fermentation occurs first under anaerobic conditions, either in the Durham tubes of lactose

broth medium or at the bottom of a lactose agar slant. Fermentation, in mediums in which the Durham tube is not present, occurs more frequently in nutrient broth medium than in dibasic phosphate peptone medium. 8 Rough and smooth colonies and 'satellite' colonies may give rise either to rapid or to slow lactose fermentation. 9 These variations from the usual descriptions given for the 'Sonne' type of organism should be considered in the laboratory diagnosis of dysenteric bacteria, for certain non lactose fermenting strains which fail to agglutinate with the common antisera may be found to belong to the 'Sonne' type.

Leukocyte Counts During Pregnancy—Carey and Litzenberg made 977 leukocyte counts in 134 normal pregnancies. A count between 10,000 and 11,000 seems to be a medium value for pregnancy, irrespective of time in pregnancy. Fifty per cent of the counts were between approximately 8,700 and 12,500 throughout the nine months of pregnancy. Less than 50 per cent of the counts were below a high normal of 10,000. Seventy-five per cent of the counts were above 8,700. Twenty-five per cent of the counts were above 12,500 or below 8,700. There was no rise in the ninth month except in a few individual cases which were not numerous enough to lift the curve. Some patients remained consistently high throughout the nine months, others remained consistently low or normal. There did not seem to be any significant difference between curves of counts in primiparas and multiparas. There may be a physiologic leukocytosis of pregnancy, but it certainly is not invariable.

Clinical Aspects of Amyloidosis—Moschowitz says that generalized amyloidosis has heretofore been largely viewed as an ominous sequel of chronic suppuration with cachexia, anemia, swelling of the liver and spleen and albuminuria as the most prominent clinical expressions. In recent years new data have been established, which have widened the diagnostic basis of this disease. These are the recognition of primary amyloidosis of so-called atypical amyloidosis of the relation of general amyloidosis to nephrotic or better termed, hypoproteinemic states and the establishment of the Bence Jones red test. Pathologically amyloidosis usually represents an involvement of the reticulo endothelial system and the pericapillary and periglandular connective tissue. Almost any tissue except the cerebrospinal substance may be involved, with a special predilection for the muscles and skin. In addition to the conventionally known causes such as tuberculosis, chronic suppuration, syphilis, Hodgkins disease and necrotizing blastomas, amyloidosis, either general or localized, is frequently associated with multiple myeloma and its attendant Bence Jones proteinuria and with ulcerative lesions of the bowels. The clinical diagnosis of amyloidosis is dependent on the following signs: 1 The enlargement of the spleen and the liver. 2 The development of signs of the hypoproteinemic syndrome consequent on the involvement of the kidney. These are proteinuria, diminished blood proteins, hypercholesterolemia and generalized anasarca. In later stages, general arterial hypertension and azotemia may develop. The latter may occur without a coexisting hypertension, in contradistinction to other varieties of renal disease associated with hypertension. 3 Purpura of the skin. This sign has been less commonly observed but has been reported often enough to be regarded as a symptom of the

disease. 4 The Bennhold congo red test, which forms the most important confirmatory test of amyloidosis. A 100 per cent retention of the dye is diagnostic. There is abundant evidence that amyloidosis is clinically reversible, whether it is anatomically reversible has not yet been definitely proved. Atypical amyloidosis constitutes a diverse variety of anatomic lesions. Clinically they may thus far be classified into four groups: cases simulating scleroderma, cases simulating myotonia, cases simulating tumor of the tongue, and those associated with deforming arthritis.

Identity of Sprue, Nontropical Sprue and Celiac Disease—Hanes and McBryde discuss a syndrome that has acquired many names during its curious history. "Tropical sprue" is an unfortunate name because it gives the erroneous impression that sprue does not occur in temperate climates. For many years, however, sprue has been known to be endemic in North Carolina and Virginia, and from the states farther south many cases have been recorded. When sprue was found to occur in temperate climates it was termed "nontropical sprue," and more recently the term "idiopathic steatorrhea" has been coined for the syndrome, to distinguish it from pancreatic and other steatorrheas. Gee in 1888 gave a brief description of a curious wasting disease of children which he termed "the coeliac disease." Herter, working with Holt in New York, published in 1908 a monograph entitled "Intestinal Infantilism," and Heubner in Germany described a condition in young children called by him "verdaunungsinsuffizienz" or "chronic intestinal indigestion." It is now universally recognized that Gee, Herter and Heubner were describing identical syndromes under different names. The authors agree with Thaysen that all these names are designations for the same underlying pathologic condition occurring both in adults and in children, and since the name "sprue" obviously has priority over all others, they think it best to adhere to the term "sprue" or (to broaden the conception somewhat) "the sprue syndrome." Within the past year nine patients with the sprue syndrome came under the authors' observation, the disease began in infancy in two and in adult life in seven, none of the patients

had ever resided in the tropics. Neither sprue nor celiac disease presents a definite and constant pathologic picture. The changes in the intestine are those of chronic inflammation and edema, possibly the result of secondary infection, and atrophy of the whole intestine. The other organs show simply the effects of chronic malnutrition. The great depletion of the panniculus adiposus, common to the two syndromes is the most striking pathologic change. The absence of pathologic changes at necropsy strongly supports the theory that a disorder of metabolism, or a deficiency state, is a probable etiologic factor. The stools both of patients with sprue and of those with celiac disease contain an excess of fat, the fat content being about three times greater than normal, but it is generally agreed that the fat-splitting function is normal, in contrast to the condition existing in steatorrhea due to pancreatic deficiency. The anemia of sprue is typically first hypochromic, later becoming hyperchromic and macrocytic. There are, however, exceptions to this rule. The typical anemia of celiac disease, or infantile sprue, is hypochromic and only rarely becomes hyperchromic and macrocytic. Low curves for sugar content of the blood (after the ingestion of 15 Gm. of dextrose per kilogram of body weight) have been found with greater than normal frequency in cases of "tropical" sprue, of "non tropical" sprue and of celiac disease. The authors believe that the constant low blood sugar curve is one of the most helpful differential signs in the sprue syndrome. They emphasize that whether one accepts celiac disease as the infantile analogue of sprue in adults is not a matter of indifference. Nothing is more certain than that the treatment of sprue with liver has completely altered the outlook in cases of this disease. Rhoads and Miller have shown that even the most severe and resistant sprue yields promptly to what Minot called "adequate liver therapy," and the authors' experience confirms this. They believe that equally favorable results will follow the application of adequate liver therapy to celiac disease.

Thrombosis of Cavernous Sinus—Although Groves' study concerns itself chiefly with the aseptic types of thrombosis of the cavernous sinus, he covers the anatomic aspects, the etiology, the symptomatology and the treatment. He discusses a number of case reports. He concludes that there are septic and aseptic types of thrombosis of the cavernous sinus. The aseptic types are caused by penetrating injuries involving the sinus by accidental injury to the sinus during an operation in its neighborhood and by fracture of the skull and injury to the head. In this group must also be included the marasmic types of thrombosis. In the septic types, in which the thrombosis or thrombophlebitis reaches the cavernous sinus by way of its afferent vessels, the mortality is practically 100 per cent. In those cases in which the condition is septic and of the restrained or chronic compensatory type, in which the thrombotic process reaches the cavernous sinus by retrograde action along its efferent vessels, there is some hope of recovery. In the cases of this group in which recovery occurred the thrombotic process in the cavernous sinus itself must have been aseptic, although originating from a septic source elsewhere.

The percentage of recovery from all types of thrombosis of the cavernous sinus is probably not greater than 7 per cent. The percentage of recovery from the purely aseptic types is considerably higher. Operations on the cavernous sinus have been extremely disappointing and have shown poorer results than nonoperative treatment. When the thrombosis originates from a septic source the focus should be vigorously treated and eradicated. The cavernous sinus itself should be let alone. As an exception to this general statement, it would seem that ligation of the carotid artery, as proposed by Cagleton, might prove beneficial.

Hot Hypochlorites for Destroying Mycobacterium Tuberculosis.—Costigan found that heating suspensions of Mycobacterium tuberculosis (human strain) to 60 C for five minutes does not destroy the organism. The hypochlorite solution of low alkalinity, containing 50 parts of available chlorine per million parts of water heated to 50 C, destroys Mycobacterium tuberculosis in two and one-half minutes heated to 55 C. It destroys it in one minute, and heated to 60 C it destroys it in one-half minute. The hypochlorite solution of low alkalinity containing 200 parts of available chlorine per million parts of water heated to 50 C destroys Mycobacterium tuberculosis in one minute, heated to 55 C and 60 C, it destroys it in one-half minute.

Effect of Vitamin D on Linear Growth in Infancy.—Stearns and her associates report investigations on the effect of vitamin D on the growth of infants carried on for a period of seven years. The rate of growth in length of infants given one teaspoonful of high grade cod liver oil (from 340 to 400 U S P units of vitamin D daily) was compared with the rate of linear growth of infants given the same type of diet but with the source of vitamin D from irradiated milk (from 60 to 135 U S P units of vitamin D daily) or its vitamin D equivalent as cod liver oil or cod liver oil concentrate milk, and with standard growth rates reported in the literature. A review of the growth standards shows that the rate of linear growth in infancy is increasing. Standards reported in 1929 and 1933 show rates of growth definitely increased over those of older standards. Infants given from 340 to 400 U S P units of vitamin D daily grow at rates definitely more rapid than those of even the recent standards. Infants ingesting from 60 to 135 U S P units of vitamin D daily grow at the same rate as the recent standards. Exposure to sunlight increased the rate of growth in the few infants in whom this measure was tried and who were receiving the lower of the two stated amounts of vitamin D. The increased rate of linear growth is ascribed chiefly to the increased intake of vitamin D and its resultant effect on skeletal growth. Although the influence of vitamin A has not been entirely excluded, certain of the observations recorded indicate that vitamin A was not the limiting factor in the growth of the infants studied.

Treatment of Pertussis with Intranasal Antigen.—During the interval between May 1935 and February 1936 Slesinger treated twenty-four active cases of whooping cough in various stages of the disease by the intranasal administration of a soluble antigen prepared from Haemophilus pertussis. The antigen consisted of a solution of soluble substances derived from recently isolated cultures of Haemophilus pertussis and represented the soluble protein of about 20,000 million organisms per cubic centimeter. The patient was placed in the recumbent posture with the head held in a dependent position below the level of the body. Ten drops of the antigen was

instilled in each nostril. The patient was kept in this position for two or three minutes in order to permit proper absorption. Treatments were usually given daily, in some cases they were given every second day. The total number of treatments varied from four to twelve. Summarizing his observation on the twenty-four cases treated in this manner, he says that of this series 45.8 per cent showed marked improvement, 29.2 per cent showed moderate improvement, and 25 per cent showed slight or no improvement. The antigen was used prophylactically in three cases; two patients developed mild attacks and one patient did not develop any symptoms. The antigen can be administered with ease. There are no reactions, and the nasal mucosa is not irritated.

Prophylactic Pertussis Immunization—Shorr checked the efficacy of larger doses of the Sauer vaccine and evaluated the prophylactic efficacy of a toxin developed by Mishulow, which was being distributed by the New York City Department of Health and which had been in general use therapeutically since 1930. Summarizing his observations, he says that of seventy-four children injected with the varying doses of pertussis vaccine and followed over a period of thirty months, eleven developed whooping cough, giving an incidence of 14.8 per cent. A comparable number of controls (seventy-two) followed over a somewhat shorter period (nineteen months) showed an incidence of 36.1 per cent of whooping cough developing during this time. The subcutaneous or intramuscular injection of pertussis vaccine in amounts of not less than 65 billion bacilli has apparently afforded complete protection of those children subsequently exposed or has resulted in a marked amelioration of symptoms in the few who developed whooping cough. The intracutaneous route of administration, although associated with rather marked local reactions, gave an agglutinin response comparable in titer with that found in children receiving from seven to eight times as much subcutaneously or intramuscularly, and even in small amounts (10 billions) was apparently able to modify the infection when it occurred. The use of the Mishulow vaccine compares favorably with that of Sauer in its prophylactic effect, and for large scale prophylactic usage eliminates the necessity of obtaining freshly isolated strains to be grown on culture mediums containing human blood.

Vitamin D Irradiated and Vitamin D Yeast-Fed Milk.—Elev and his collaborators studied the relative prophylactic values of two types of vitamin D milk when it was employed as the only source of antirachitic substances in artificially fed infants. During the period of observation which began in January, 1935 and extended through May, 1935, twenty-six infants were studied. All infants were placed on vitamin D milk within the same week and therefore it was possible to

follow the entire group for a period of five months. The age incidence of the patients at the beginning of the study varied from two to twelve weeks. With the exception of three infants who had received 1 drachm (4 cc.) of plain cod liver oil daily for four weeks, and three infants who had received a similar amount at irregular intervals for from two to three weeks, none of the infants had received any antirachitic substance. Ten were girls and sixteen were boys. The group contained one set of twins and three premature infants. In order to maintain a standard potency of the milk, biologic assays were made at regular intervals. The milk, which was delivered free to each family every morning, contained 135 U. S. P. and 432 U. S. P. vitamin D units, the former being obtained by irradiation and the latter by feeding the cattle known quantities of yeast. Thirteen infants received the irradiated and fourteen the yeast milk. The formulas consisted of whole milk, corn syrup and water and were altered only during infections or when it became necessary to increase the amounts on account of the increasing requirements of the babies. Antiscorbutic substances in the form of orange or tomato juice were added to the diet at appropriate periods as were cooked cereals and strained vegetables. Thus the diet met all the known nutritional, mineral and vitamin requirements with the exception of vitamin D, which was supplied solely from the milk. The results of this study showed that none of the infants developed rickets either by clinical or by roentgen examination, regardless of which milk they received. In the majority of instances the rate of growth was within the accepted curve of normal growth and development. In view of these observations it would appear that both the irradiated vitamin D milk and the yeast fed vitamin D milk were adequate as prophylactic measures.

Treatment of Chronically Infected Prostate.—Milliken presents some of the most promising ideas on the treatment of the chronically infected prostate that have been advanced during recent years. He shows that infection of the seminal vesicles must be assumed as nearly always concomitant with chronic prostatitis and must be treated at the same time. What ever may have been the origin of the infection and regardless of what particular organism may be demonstrated in the secretions, the treatment is the same. Any form of treatment in order to produce the best results must be supplemented by

measures calculated to improve the general health. Tonics, proper exercise in the open air, avoidance of the sedentary life and the eradication of all discoverable foci of infection are important aids to any other form of treatment. The intravenous injection once a week of from 0.3 to 0.45 Gm of neocarsphenamine has seemed to be of definite value in some cases. Any moderate form of exercise that improves the circulation of the perineum and pelvic organs is desirable, walking, especially as exemplified in golf, is probably the best. A sedentary occupation, long sessions at the card table, and prolonged automobile or train rides are certainly not conducive to a cure. Many cases disappear far more rapidly after an infection in tonsils or teeth has been eradicated. About the value of stock and autogenous vaccines, serums and foreign proteins, and the intravenous injection of various chemical antiseptics, the author says that it cannot be denied that any or all of these may have some supplemental value in certain cases, but none of them give results at all commensurate with the cost or the time involved. Of somewhat better promise is the injection of a dilution of 1:1,500 hydrochloric acid. Ten cc of this is injected every day for five days, then every other day until ten more doses have been given. No matter what other form of treatment may be employed, massage must be used. However, too early, too frequent and too vigorous massage after gonorrheal infection of the gland may be the cause of many persistent cases. To be effective in the chronic case, massage must be firm and thorough. In order that there may be complete recovery from whatever reaction is induced, intervals of from five to seven days, or in some cases even longer, are better than shorter ones. Other methods of local treatment that seem most logical are direct injection of the gland with 1 per cent mercurochrome solution, drainage of the prostate by transurethral resection, and direct application of heat to the gland by any means available. The author describes a double rubber bag, the construction of which makes possible the application of any degree of heat desired to the rectal side of the vesicles and prostate, while tepid fluid circulating in the posterior cavity protects the normal rectum against possible ill effects of heat. Each case of chronic prostatitis must be treated individually as the judgment of the experienced urologist may suggest.

Relief of Postoperative Intestinal Atony with Physostigmine Derivative—Schlaepfer first used prostigmine (the dimethyl-carbamate ester of 3-hydroxy-phenyl-trimethylammonium methyl sulfate) as an injectable stimulant for postoperative peristalsis in the fall of 1932. He was able to confirm the experiences of other observers that he was dealing

with an excellent peristaltic agent—one without undesirable by effects. For injections, he always uses the intramuscular route. He gives the first injection from eight to ten hours after laparotomy. However, in cases in which he expects considerable stasis as a result of prolonged exposure of the open abdominal cavity and handling of the intestine, he feels justified in shortening the interval before the first injection. The second injection is usually given after an eight-hour interval. About fifteen to twenty minutes after the injection, increased peristalsis becomes noticeable by expulsion of flatus. The great majority of the author's patients did not complain of cramps. Half an hour after the injection, a glycerin-water enema (100 cc) is given. This usually is followed by a copious evacuation. He used and is using the physostigmine derivative as a preventive measure against atony following major abdominal operations, when other measures, such as the light arc or electric pad in conjunction with enemas would probably not suffice. Cases of acute abdominal conditions necessitating immediate surgery, such as appendicitis, perforated gastric or duodenal ulcer, or cholecystitis, are greatly benefited by the early and persistent postoperative use of the physostigmine derivative until normal peristalsis is reestablished. Following operations for hemorrhoids, anal fistula and fissures in which the peristalsis is checked for several days by opiates, it proves valuable in starting peristalsis. In paralytic ileus due to peritonitis, it is helpful in promoting and sustaining effective peristalsis. A change in technic, which proved superior to the original procedure, was the replacement of the glycerin-water enema by a slowly given enema of 100 cc of 15 per cent solution of sodium chloride.

Goat's Milk Anemia—Orten and Smith point out that several hypotheses have been advanced to explain the anemia-producing effect of goat's milk. One of these postulates the presence of toxic substances in the milk, perhaps certain types of fatty acids in the milk fat which promote an increased rate of erythrocyte destruction and thus cause an anemia. However, the fact that the administration of relatively large amounts of fatty acids prepared from goat's milk, or mixtures of pure fatty acids, to animals receiving either a mixed ration or a goat's milk diet had no noticeable effect on the composition of the blood seems to preclude the possibility of the presence of a hemolytic agent in the fat of goat's milk. Another explanation of the cause of goat's milk anemia is that this type of milk is deficient in some necessary hematogenic substance, such as iron, or as has been recently suggested, an essential organic substance perhaps related to the "extrinsic factor" said to be needed for the prevention of pernicious anemia in man. The evidence on which the latter view is based was obtained chiefly from experiments on young albino rats fed an exclusive goat's milk diet. A severe hyperchromic anemia developed and a prompt cure resulted from treatment with liver or liver extract or with an extract of yeast. As a result, the suggestion has been made that rats given goat's milk exclusively should serve as satisfactory test animals for the assay of preparations to be used in the treatment of pernicious anemia. The possible practical importance of this alleged relation between the anemia-producing deficiency of goat's milk and the "extrinsic factor" said to be involved in human pernicious anemia suggested the need of a further study of the problem. The authors made such studies on male albino rats and record their results in tables. They reach the conclusion that a diet composed exclusively of goat's milk supplemented with iron and copper supports good growth and permits the maintenance of a normal blood picture in rats for a period of at least ten weeks. This observation adds further to the evidence that goat's milk itself is not deficient in any necessary organic hematogenic substance, such as the alleged "extrinsic factor" related to pernicious anemia in man.

Artificial Silk Keratitis—Rankine observed 1,598 cases in two years. The earliest symptom was blurring of vision, with the appearance of halos round lights. This stamped the disorder as a corneal one from the first. In a comparatively small number of cases recovery took place without the development of further symptoms, and, there being no slit lamp available, the only objective sign was conjunctival injection, which was never very severe. In the great majority, however, the condition progressed, and the blurring was followed in from half an hour to several hours by a feeling of grittiness under the lids, photophobia, lacrimation, often blepharospasm, frequently drooping of the lids without spasm, dull aching at the back of the eyes and headache. In cases which went on to irritation, fluorescein staining showed more or less desquamation of the corneal epithelium on the center of the cornea. The destruction of tissue was essentially superficial. The keratitis was always accompanied by circumcorneal injection and by conjunctival injection of all degrees. The breath of those who were affected was pungent, the odor being suggestive of onions (at one stage of manufacture there is produced thioformaldehyde). Removal from the spinning room or acid house was almost always necessary, the most welcomed active treatment was the application of a weak cocaine ointment, such as 0.5 per cent in zinc ointment. The keratitis affected the spinners and the "cake changers" in about equal proportions. At this factory important points were noted which do not seem to have attracted attention elsewhere. First, about two thirds of the men appeared to be immune. Searching examinations revealed nothing that would explain this immunity. The method of onset of symptoms was given special study. Almost invariably at least two eight-hour exposures were necessary to produce symptoms. It seems that, given sufficient cause, three or four exposures will produce keratitis in susceptible workers. Symptoms frequently began not during exposure but after leaving work. Many workers even went home and to sleep without symptoms and found blurring present on awakening. The "droplets" theory of etiology was ruled out early in this investigation. A gaseous cause was decided as being the most probable. The ventilation was faulty in that fresh air was introduced at ground level and at roof level, while extraction was only through the spinning boxes, at waist level. It was suggested that, if the induction pipes on the ground level were made to act as extraction pipes, there would then be a uniformly downward system of ventilation. This suggestion was adopted and, when put in operation, produced a dramatic drop in the number of cases of keratitis. One outbreak of keratitis could not be attributed to any fault in the extraction system in the spinning room. On inquiry it was found that thioformaldehyde was responsible.

Acute Toxemia of Burns—Wilson and his associates used adrenal cortex extract as an adjuvant measure in the treatment of three cases of acute toxemia due to burns. A fatal issue

was predicted in two of the three cases. In man, adrenal cortex extract has been employed in a few instances in the treatment of bacterial infections and toxicosis, so far as the authors are aware, no reports are available of its use in burns. Regarding the mode of action of adrenal cortex extract in combating acute toxemia of burns, they have little positive information. Their observations indicate that it results in an increased efficiency of the circulatory mechanism. The only alterations found in the blood of burned individuals during extract therapy were in the sedimentation rate and (once) in corpuscular content. There is no satisfactory evidence that acute toxemia of burns produces a functional insufficiency of the suprarenals, changes in blood chemistry during the toxic phase of burns, though in certain instances they bear some resemblance to changes after adrenalectomy, are irregular and frequently insignificant. Moreover, pathologic studies have revealed little evidence of damage to the adrenals. Adrenal cortex extract should be considered an adjuvant measure and not a substitute for proved and recognized preventive treatment in acute toxemia of burns and also possibly, as future trial may show, in the stage of circulatory collapse (secondary shock). Some precaution against liver damage is advisable. Continuous intravenous infusion of dextrose saline solution from an early stage of extensive and severe burns may mitigate the injury to the liver cells. The quantities of extract required for maintenance of circulatory efficiency are evidently considerable. Of the concentrated extract now available, 1 cc. every two hours from the onset of acute toxemia will suffice for a child, while for an adult 2 cc. or more every hour is necessary. Injections should be continued for 100 hours after injury and should be renewed if toxic manifestations reappear.

*Increase in Diameter of Aorta with Age. J. B. Cleland—p. 818

Increase in Diameter of Aorta with Age—While doing postmortem examinations on young persons, Cleland noticed that the diameter of the aorta is definitely less than that of older persons. He decided to take measurements of the diameter of the aorta just above the aortic valve and an inch or so above the diaphragm, to see whether there was any regular increase in size with age. He shows with tables of males and of females that there is a definite and regular increase in diameter of the aorta with advancing years. The results are tabulated by decades. The aortas of 227 males and 147 females have been measured and tabulated. The table for males indicates that the average measurement above the valve in those who were below the age of 21 was 1.7 cm. and that the average above the diaphragm was 1.2 cm. For those between the ages of 21 and 30 the average measurements were 1.82 and 1.36 cm. respectively, between 30 and 40, 2.05 and 1.39, between 40 and 50, 2.21 and 1.6 cm. and so on, those over 70 years of age showing average values of 2.75 and 1.92 cm., and those over 80, 3.15 and 2.22 cm. The measurements in females showed slightly lower values, but here too an increase could be noted with the advance in years.

Liver Function and Its Significance in Disease—Brooks discusses the function of the liver in fat, protein, carbohydrate and nucleoprotein metabolism. In the protective function of the liver, sulfur, derived largely from the cystine of the food, is in the course of protein metabolism removed in the liver, oxidized to sulfuric acid and neutralized with sodium and potassium. The inorganic sulfates so formed are excreted in the

urine. Some of the unabsorbed amino acids undergo putrefaction in the large intestine with the formation of indole, skatole and phenol. These are absorbed into the portal blood and conjugated with inorganic sulfates and glucuronates in the liver and are then passed on for excretion in the urine. Since indole, skatole and plicinol are extremely toxic bodies, while the ethereal sulfates and glucuronates are harmless waste products, this would seem a most important function. An increase in the phenol of the blood has been reported in an advanced case of cirrhosis, and it is of interest that Foster and Kalin have used the power of the organism to conjugate phenols as a test of liver efficiency. Other poisons, such as the heavy metals, dysentery toxin, ricin and abrin, are excreted in the bile. In this connection the actively phagocytic Kupffer cells probably play an important part. There is also reason to believe that bacteria are removed from the blood stream, killed and excreted by the liver. Vauthier, moreover, has collected evidence which suggests that the liver plays a protective part in anaphylactic conditions.

*Experimental Study of Two Pathogenic Forms of Acute Pulmonary Edema. E. Coelho and M. Ribeiro.—p. 383

Forms of Acute Pulmonary Edema—According to Coelho and Ribeiro, acute pulmonary edema has been observed in four conditions, namely, in claudication of the left ventricle, venous stasis with acute pressure in the pulmonary veins, toxic reactions from various substances and nervous edema (accompanying cerebral disturbance). The mechanism, they believe, is of two types and they describe the two forms of experimental pulmonary edema. In dogs, after complete ligation of the ascending aorta, an immediate dilatation of the left ventricle accompanied by intense pulmonary edema could be observed. The second pathogenic form of acute pulmonary edema in dogs could be produced by the introduction into the circulation of various toxic substances. When the edema following ligation of the aorta was compared with that produced by injection of silver nitrate into the wall of the right ventricle, marked differences in the heart, in the appearance of the lungs and in the edema itself were noticed. In order to control the mechanical factors they injected alcohol into the right ventricle or into the pulmonary artery and were never able to produce edema with this substance. They concluded therefore that pulmonary edema produced by injections of a solution of silver nitrate into the saphenous vein or the right ventricle of the dog is an edema of toxic origin and identical with the toxic edema of man. The edema produced by ligation of the aorta or by partial necrosis of the left ventricle is of a mechanical origin, produced by the insufficiency of the left ventricle and is identical with that in man produced by failure of the left side of the heart.

Lipoid Nephrosis After Aurotherapy. R. J. Weissenbach, J. Martineau, J. Brocard and A. Malinsky.—p. 1076

Acute Mercurial Nephritis—Mach and Oppikofer report the case of a man, aged 32, after ingestion of 100 cc. of a 1 per cent solution of mercuric chloride. In the course of the secondary nephritis resulting from this poisoning the blood urea rose to a level of 6.55 Gm per thousand and was quickly lowered, returning to normal in about two weeks. After this recovery the patient showed no signs whatever of renal insufficiency. The nephritis developed in four periods: (1) a phase of onset, immediately after the absorption of the poison, characterized by severe lumbar pain and vomiting, (2) a phase of anuria beginning the day after the intoxication and lasting for eight days, (3) a first period of diuresis, in the course of which the level of blood urea continued to rise to

its maximum level on the sixteenth day after the intoxication, vomiting practically ceased during this phase, (4) a second period of diuresis, accompanied by lowering of the blood urea in the course of fourteen days to a practically normal level. The striking feature of the intoxication was that in spite of the large amount of the metal ingested the digestive disorders were insignificant. Furthermore, in spite of some retention of chlorides the plasma chloride continued to become lowered, and signs of disturbed chloride balance resulting from administration of the salt became apparent in spite of the low plasma chloride content. The authors believe that this fact indicates that the treatment of such intoxications by administration of chlorides is an individual matter and is not always indicated.

Facial Paralysis in Chronic Nephritis—Merklen and Israel report the case of a woman, aged 35, who belonged in the class of those having a chronic nephritis with azotemia and hypertension. On the basis of this condition, she developed a left facial paralysis which was inconstant and a right facial paralysis which was severe and developed in three attacks. Recovery from the last occurred after about three months except for the persistence of some stiffness in the movements of the forehead. The most probable explanation for this complication is as an accident accompanying the azotemia.

*Studies of Anisocytosis of Erythrocytes and Their Applications to Diagnosis of Diseases of Liver. A. Archi.—p. 561

Anisocytosis and Diagnosis of Liver Diseases—Archi believes that an increase in the erythrocyte diameters is not encountered in all liver diseases but only in those in which there is a diffuse anatomic lesion of the entire liver parenchyma. Such changes are lacking in circumscribed lesions, as, for example, abscesses, hydatid cysts and metastatic neoplasms. The increase in diameter is observed in the chronic liver disorders of irreversible character as well as in the acute conditions, such as atrophic cirrhosis, pigmentary cirrhosis, interstitial hepatitis and cyanotic atrophy. In diseases of the biliary tracts, the erythrocytometric formula is usually normal. In retention icterus, on the contrary, increases in erythrocyte size may or may not be present. The increase in diameter of the erythrocytes is thus probably not due wholly to the presence of a clinically evident jaundice. In spite of these observations, some obscurity remains as to the relations between an increase in erythrocyte size and hepatic disorder. No clear cut diagnostic or prognostic significance can yet be applied to anisocytosis in liver disease.

Rheumatic Disorders Caused by Chemicals—Tzanck and his colleagues studied all the cases of rheumatism developing in the venereal disease clinic of the Broca Hospital and the St. Antoine Hospital with regard to rheumatism developing in the course of chemotherapy. Rheumatic symptoms developed almost always in young subjects who had never previously shown similar manifestations. Women were more frequently involved than men. The articular symptoms, however, could develop at any time in the series of the chemical treatments. The dose of chemical seemed to play little part. The remarkable feature was the apparent brevity of the incubation period. The attack usually occurred three or four hours after the injection, although it might be two or three days. Three main types could be distinguished: simple polyarthralgia was the most frequent, a form of hydrarthrosis, and a form of febrile poly-

articular type were also noted. Cutaneous or visceral manifestations were frequently associated with the joint symptoms. Any of the common complications of chemotherapy, however, could accompany the articular manifestations. According to the authors' observations, arthritic symptoms were encountered more frequently after the administration of arsenicals than after other forms of chemical therapy. Symptoms have been recorded, however, after bismuth, mercury and gold compounds, barbiturates and other chemical agents. The nature of the reaction introduced by chemical agents is difficult to determine. The infectious and the toxic theories have been advanced to explain them, but the authors feel that the most important factor is probably individual intolerance to the specific agent. From a clinical and physiopathologic standpoint the manifestations are similar regardless of the exciting cause. The mechanism is probably essentially vascular and reveals a sudden disturbance of the neurovegetative system.

Near and Late Results of Endocrine Gland Grafts—Hélène Aouslender—p. 246

Sexual Hormone Preparations and Hypophysis—Fischer and Engel investigated the effects of injections of estrogenic substance on the estrual cycle of rats. Histologic examination of rats having received strong doses of estrogenic substance gave the following results. The ovaries contained more or less numerous corpora lutea, sometimes well vascularized new ones and sometimes old ones. The follicles were small and immature at the beginning of the cycle but enlarged progressively toward the tenth and twelfth days. The histologic aspect of the uterus corresponded to that of the vagina and remained essentially unchanged. It was concluded that observation of the genital cycle in selected rats is a good method for examining the hypophyseal function. No other hormone except estrogenic substance can change the cycle. Estrogenic substance given in large doses is capable of suppressing several estrual cycles and prolonging the duration of the intermenstrual period up to two weeks. This phenomenon is accompanied by some morphologic changes which suggest that the suppression of the cycle is the result of the absence of the hypophyseal gonad stimulating action necessary for the maturation of the follicles. The number of basophils is diminished in estrogenic substance treatment. The hypophysis of castrated rats is more active and that of animals treated with estrogenic substance less active than that of normal animals. The action of castration on the hypophysis can be prevented by estrogenic substance but not by other hormones. The inhibition of estrogenic substance on the hypophysis explains the action of this hormone on the genital cycle of the rat. It is probable that estrogenic substance exerts its action in physiologic conditions also, thus explaining the humoral hypophyseal ovarian automatism. The administration of estrogenic substance to nonmature rats represses their genital development and slows their growth. These two effects are explained by the inhibiting action on the production of the gonad stimulating hormone and the hormone of growth of the hypophysis. The thyroid hormone has apparently no influence on the gonad stimulating function of the hypophysis, but it exerts a depressing action on the ovaries. This action is one sided, since the gonads have no influence on the thyroid.

*Premenstrual Elevation of Temperature in Pulmonary Tuberculosis—R. Weiller—p. 233

Premenstrual Elevation of Temperature in Tuberculosis—Weiller says that all the stages of genital life in young women exert a more or less damaging influence on the evolution of pulmonary tuberculosis. He reviews the literature

and discusses personal observations on temperature curves, especially around the menstrual period of normal women and those with pulmonary tuberculosis. He feels that one can say that, in tuberculosis of women having regular periods or those showing an active amenorrhea, a premenstrual elevation of temperature is observed with extraordinary frequency. The rise may start even as long as two weeks before the period begins depending on the activity of the pulmonary lesions. The elevation of temperature is slight in inactive cases and marked in active ones. All types of intermediate temperature curves were also observed.

Pathology and Therapy of Cheyne-Stokes—Roth states that it was pointed out in 1909 that by voluntarily increased respiration the Cheyne-Stokes respiratory phenomenon may be elicited in normal subjects. The author's own studies revealed that this is possible only in some persons, most readily in those who are predisposed to hyperventilation tetany. He further points out that nearly all investigators are agreed that a reduced irritability of the respiratory center plays a part in the Cheyne-Stokes respiration. It is his aim to give experimental proof that the respiratory center is severely impaired in the Cheyne-Stokes phenomenon. He cites tests which seem to demonstrate that the severity of the disturbance in the respiratory center differs in the individual cases. In 1916 he called attention to the fact that, in addition to the respiratory center, the center of the cardiac vagus may likewise be involved. He demonstrates electrocardiograms illustrating this. Then he evaluates the various therapeutic procedures, such as the injection of theophylline with ethylenediamine, lobeline or phosphatine, and so on. In some cases he obtained good results with oxygen treatment. In recent years however, he observed that an admixture of carbon dioxide to the oxygen had an even better effect, and since 1933 he has used the oxygen-carbon dioxide mixture regularly in Cheyne-Stokes cases. In trying to explain the favorable action of this gas mixture, he suggests that its administration probably results in a chemical composition of the blood that is capable of stimulating the function of even a severely impaired respiratory center.

Idiopathic Chronic Steatorrhea—Allodi reports a case of idiopathic chronic steatorrhea in a patient, aged 33, who had never been out of Turin. In this case it was possible to make all clinical and laboratory examinations so that a definite diagnosis was established. The syndrome could be superimposed on that of tropical sprue with a picture similar to that of pernicious anemia, which was differentiable from typical pernicious anemia because of the presence of Castle's intrinsic factor in the gastric juice of the patient. The daily oral administration of 300 Gm. of liver extract brought about a rapid improvement in the general condition and resulted in complete recovery of the patient. The author believes that idiopathic chronic steatorrhea is caused by a lack of assimilation of fats and metals by the organism owing to the presence of inflammatory lesions in the duodenum and that anemia in such cases is probably the result of the absence of vitamin D in the gastric juice, which factor is found in the liver.

From Hypotensive Pneumothorax to Surgical Detention of Lung
F. Tobè—p. 627
*Group-Specific Properties of Vernix Caseosa F. Tarsitano—p. 642

Group Specific Properties of Vernix Caseosa.—Tarsitano made determinations of the group-specific properties of vernix caseosa of infants classified according to blood groups. The determinations were made on stains. The author concludes that vernix caseosa has group-specific properties as shown by the adsorption of specific iso agglutinins from the blood serum when the latter is placed in contact with the stained material. There is a perfect correspondence between the blood group to which the infant belongs and the group of the stain. The latter is evaluated from the intensity of specific adsorption of iso-agglutinins from the blood serum by the stain. The quantitative value of adsorption by vernix caseosa is low compared with that of the blood erythrocytes of the infant. The specific adsorption properties are retained in the stains for about twenty-five days and can be used in medicolegal procedures for identification and other aims.

Alcohol Therapy in Nontuberculous Pulmonary Diseases in Native Soldiers of Eastern Italian Africa. E. Molinari—p. 873

Adrenal Cortex and Metabolism of Sodium Chloride—Malato's experiments are based on the fact that adrenal insufficiency is associated with a decrease of sodium chloride of the blood and increased elimination of the chloride through the urine. The purpose of the experiments was to verify the relation between the adrenal cortex and the sodium chloride metabolism. The experiments were performed on white rats a number of which were subjected to adrenalectomy and the other to acute dechloridation. The syndrome produced in the animals of the two groups was the same and consisted especially, in early spastic paralysis of the hind legs, diffuse hypertrophy of the lymphatic system structures, true hemorrhagic diatheses, especially in the gastric and intestinal mucosae, and great atonic dilatation of the stomach and intestine. From the results of the experiments the author concludes that probably primary adrenal cortex insufficiency produces secondary hypochloremia and increased elimination of the chloride through the urine in the same manner as primary chloropenia produces, secondarily, a miopragic condition of the adrenal cortex. The histologic studies of the adrenal glands of the chloropenic rats in the author's experiments showed the same type of lesions as those seen in clinical cases of acute adrenal insufficiency. The author concludes that his results have a clinical therapeutic value by pointing out the advisability of administering an associated treatment of sodium chloride and adrenal cortex extract in cases of a syndrome of primary adrenal insufficiency with secondary chloropenia (Addison's disease) as well as in the syndrome of primary chloropenia with secondary adrenal insufficiency (chloropenia caused by vomiting, diarrhea and similar conditions).

Value of Read's Formula for Determination of Basal Metabolism E. Andreucci—p. 29
Renal Lithiasis and Parathyroids A. Galluppi—p. 32

Scurvy Due to Destruction of Vitamin C by Intestinal Bacteria—Marin's patient aged 22 presented a clinical picture which was complicated by continuous persistent high fever, hemorrhagic gingivitis. A diagnosis of scurvy was made. The patient's diet did not lack vitamins especially vitamin C. During two weeks with an antiscorvy and orange juice together with vitamin C administration gave no relief. The administration

tion of liver extract and adrenal cortex extract by the intramuscular route resulted in the rapid, complete and permanent recovery of the patient. The author reviews Stepp's experiments in which the latter found that bacteria of coli and paratyphoid types destroy vitamin C. From this experiment the author concludes that in his case the predominance of coli or paratyphoid B bacilli in the patient's intestinal flora caused destruction of vitamin C which resulted first in development of avitaminosis and then in the failure of the antiscorvy treatment when the latter was administered by the mouth. The author states that scurvy is not as rare in Italy as is believed, that it may be due to disturbances of vitamin assimilation by the intestine and that it may develop into an atypical early period, as in his patient.

*Familial Porphyrinuria and Idiopathic Porphyrin S. Maugeri—p. 919
Semiferrous Carcinoma Developed in Retained Testicle Case. M. Sirolli—p. 925

Familial Porphyrinuria and Idiopathic Porphyrin—Maugeri states that the daily elimination of porphyrin through the urine, which normally amounts to 50 micrograms increases in cirrhosis of the liver, pernicious anemia, malaria, barbituric and lead poisoning and porphyria. The author reports a case of coproporphyrinuria and protoporphyrinuria in two brothers and a sister. In the three cases there was hyperchromia of the erythrocytes, bilirubinemia and intense elimination of urobilinogen and stercoral bilinogen. The globular resistance was normal. The health of the three members of the family was normal except for the presence of moderate splenomegaly. Two brothers in another family presented also porphyria associated in one with idiopathic abdominal porphyria. The author discusses the synthetic relations of porphyrin to the metabolism of hemoglobin and the similarity of the symptoms of porphyria with those of hemolytic jaundice, from which porphyria is differentiated by the existence of a porphyrinogenic factor that does not exist in hemolytic jaundice. The author admits from a clinical point of view, the existence of a condition of latent porphyria due to alterations of the metabolism of hemoglobin, which may remain latent until certain factors now unknown, change the latent condition into a syndrome of porphyria.

Diagnosis of Spondylitis Deformans—Muñoz Areños states that the diagnosis of spondylitis deformans early in the development of the disease, is difficult because of the fact that the first clinical symptoms appear late in the evolution of the vertebral lesion. Generally the patients place the cause of the condition on industrial trauma with purposes of compensation. There is always a history of vertebral insufficiency in the patient. The diagnosis is made by the roentgenogram of the involved vertebrae, which show atrophic alterations early in the disease. In more advanced stages of the disease there are zones of vertebral rarefaction, osteophytes, processes of synostosis and exostosis and deformation of the menisci and of the vertebrae, which take the characteristic aspect of a flat vertebra and in the forms of rapid evolution, processes of meniscal and vertebral destruction. The author made roentgen studies of the involved vertebrae in forty-five cases of spondylitis deformans. The majority of cases were in advanced stages. He concludes that there is no relation between trauma and spondylitis deformans. As a rule clinical symptoms of the disease appear after a period of rest not necessarily following trauma. The factors that account for the development of the clinical symptoms after a period of rest are unknown. It is plausible, however, that in patients who suffered from trauma the period of rest and not trauma in itself acted as the agent to bring the disease from a latent condition into one of evolution.

Thrombocytes in Acute Miliary Tuberculosis—Arneth asserts that in acute miliary tuberculosis there always exists a more or less severe thrombopenia. He studied the behavior of the thrombocytes in six cases of acute miliary tuberculosis paying especial attention to the qualitative changes in the platelets. In the normal thrombocytic blood picture there are two distinct groups, a left one and a right one. The left group (always from the standpoint of the observer) contains the large, longish forms of platelets, which are subdivided into those without and those with division of the granulomere. The right group contains the roundish to oval platelets, which vary in size between 2.5 and 4 microns. In discussing the thrombocytic blood picture of the six patients with miliary tuberculosis, the author says that the thrombocyte values were reduced in all the number being always below 100,000 per cubic millimeter and as a rule even below 50,000. But even when the values were below 40,000 (the critical number), there never developed a hemorrhagic diathesis, from this the author concludes that thrombopenia cannot be the only cause of that disorder. Although the degree of thrombopenia varied in different cases, there usually was a further reduction as death approached. About the qualitative thrombocytic blood picture the author says that there usually is a reduction in the longish forms (left side of the hemogram) and an increase in the roundish forms (right side) that is, it may be said that the thrombocytic blood picture shows a deviation to the right. After giving a qualitative analysis of the thrombocytes of the six patients, the author stresses the inadequacy of the mere quantitative evaluation. He shows that the reduction in the number of platelets in miliary tuberculosis is combined not merely with a deviation to the right in the qualitative picture but rather with a combination of an external right and an internal left deviation, that is, a relative increase in the roundish forms and with a corresponding simultaneous internal shifting of size to the left. The defense reaction of the organism which is expressed in the latter manifestation, of course subsides when death approaches.

Ide Reaction, a New Color Reaction for Syphilis—In describing the technic of their new reaction the Ides first outline the preparation of the extract of ox heart. Then they prepare four different solutions: (1) a cholesterolized solution (100 cc of the ox heart extract with 0.2 Gm of cholesterol), (2) a 5 per cent acacia-benzoic solution of the ox heart extract, (3) a 1 per cent alcoholic (95 per cent alcohol) crystal violet solution and (4) a 1 per cent alcoholic solution of azure II. From these four solutions they prepare the 'Ide' antigen by adding to 100 cc of the first solution 5 cc. of the second and 0.6 cc. each of the third and fourth solutions. A drop of blood (from 0.02 to 0.03 cc) is placed on a hollow slide. Before the blood coagulates, one drop (0.05 cc.) of a 3 per cent solution of sodium chloride is added and mixed with the blood. A diluted reagent solution is prepared by putting 0.2 cc of the Ide antigen into a small tube and adding to this 0.6 cc. of a 2.5 per cent solution of sodium chloride and by shaking this mixture from twenty to thirty times. One drop of this diluted reagent is mixed with the drop of blood on the slide and the entire mixture is shaken for three minutes. Immediately after this the preparation is examined under the microscope with a magnification of 50 diameters. The reaction is positive when microscopy discloses between the blood corpuscles large violet-blue particles. If these particles are absent the reaction is negative. The authors made this test and control Wassermann tests on 2,350 serums. They obtained a positive Wassermann reaction in 235 cases and a positive Ide reaction in 235 cases. However if only the absolutely sure cases are considered 235 positive Wassermann reactions correspond to 229 positive Ide reactions that is there are about ninety-seven positive Ide reactions to every 100 positive Wassermann reactions.

*New Method of Blood Transfusion P Hedenius—p 263

*Treatment of Diabetes Mellitus with Insulin Protamine E. Möller and Agnete M. Thomsen—p 308

*Tetany and Epilepsy Question of Late Spasmophilia G A Lindeboom and J E B Wientjes—p 376

Method of Blood Transfusion—Hedenius points out that at present either whole blood or citrated blood with or without a saline solution are used in blood transfusions. The whole blood method has the disadvantage that it requires the experience and skill of a trained surgeon. The citrate method provides for a more leisurely execution of the transfusion, but it introduces foreign substances into the body, which in large doses may have a poisonous effect. The author presents a new principle according to which the donor's blood is first treated so that it cannot coagulate during the time necessary for making the transfusion. This is made possible by heparinizing the donor. If the latter is intravenously injected with a dose of heparin sufficient to give him a coagulation time of twenty minutes, a similar amount of time is available for carrying out the transfusion. From the amount of heparin injected in the donor, a quantity proportional to the amount of transferred blood, that is, generally a tenth part at the most, goes over to the recipient in the transfusion. This amount of heparin has, however, proved in the transfusion experiments to be too little to lengthen the coagulation time of the recipient. This method, therefore, does not appear to lead to any inhibition of the recipient's coagulation mechanism, which one is often anxious to avoid hurting. Furthermore, this method does away with certain inconveniences, such as the possibility of coagulation in needles, tubes and so on. The author first determines the coagulation time of the donor and the recipient. At this time the donor is given an injection of heparin, and ten minutes later his coagulation time is again determined. Soon thereafter the transfusion is begun, which in some cases is purposely prolonged. Ten minutes after the completion of the transfusion, the coagulation time of the recipient is once more determined. In the author's cases the recipients always had the same coagulation time before as after the transfusion. In stressing the advantages of this heparin method, he says that even the simplest apparatus may be used. All a doctor need take along for a blood transfusion are a syringe and a heparin ampul.

Treatment of Diabetes Mellitus with Insulin Protamine—Möller and Thomsen point out that during the last few years two methods for retarding the effects of subcutaneously injected insulin have been reported. Clausen obtains the desired retardation by adding to the insulin solution minute amounts of epinephrine (1:50,000) and explains the effect as being due to the vasoconstriction caused by this substance. By changing the amount of epinephrine, the retarding effect may be graduated according to the exigencies of the individual case. Hagedorn, Jensen and others effect retardation in quite a different way, namely, by using insulin protamine. This preparation is injected as a suspension and is thought to become gradually dissolved or broken down. The authors describe their experiences with insulin protamine in the treatment of ten diabetic patients. They found that it acts more slowly than ordinary insulin (for about twice as long), reduces the oscillations of the average diurnal blood sugar curve, allows a considerable saving of insulin (in this series an average of 28 per cent) makes the hypoglycemic attacks less violent but more protracted, and makes it possible after careful adjustment completely to free the patient from these attacks.

Tetany and Epilepsy—After reviewing the literature on the subject Lindeboom and Wientjes describe the case of a patient with epileptiform convulsions. These attacks began from early childhood until the patient was 17 years of age. Whereas at first the condition had been regarded as epilepsy (prompt reaction to phenobarbital), the patient developed during his twenty-third year, in addition to the attacks the symptoms of a severe tetany. From the latter condition the patient was freed by the employment of a fraction of viosterol which was given in response to this not only but also the epileptiform attacks that the case is—

Adequate antepartum care should comprise supervision over the condition of the mother, beginning not later than the fifth month of gestation. It should include periodic blood pressure readings, regular chemical and microscopic examinations of the urine, Wassermann or Kahn tests, internal pelvic measurements, determination of the position of the fetus and of the existence of heart tones, a complete physical exami-

three, or 5.6 per cent, were positive. It is obvious from these figures that serologic tests are not carried out on pregnant women with anywhere near the frequency with which they should be done.

The making of a Wassermann and Kahn test early should be included as a necessary part of the antepartum care of the mother.

DELIVERY

Breech presentation was more frequent among premature infants than among full-term infants. Of the former, 18.6 per cent were breech, and of the latter, 11.6 per cent. The onset of labor was spontaneous for 88 per cent of the premature and for 91.3 per cent of the full-term. For both groups, 6.4 per cent were associated with cesarean section, 5.6 per cent of the premature deaths were in cases in which labor was induced.

The most frequent conditions assigned as indications for inducing labor were toxemia, placenta praevia and uterine bleeding.

The most frequent methods of inducing labor were the use of a bag, oxytocics, manual dilation, and artificial rupture of membranes as shown by table 3.

Forceps and version were more frequently used in the delivery of full-term infants than in delivery of the premature.

Cesarean operations were performed on fifty-one of the mothers of the 795 premature infants who died. The most frequent indications in the case of premature infants for cesarean section were toxemia and placenta praevia, as shown in table 4.

TABLE 6—Type of Operative Procedure in Delivery Other Than Cesarean Section

| Type of Operation | Premature Infants |
|------------------------------|-------------------|
| High forceps | 1 |
| Mid forceps | 7 |
| Low forceps | 28 |
| Version | 14 |

|---------------------|-------------------|
| None | 79 |
| Nonquestionable use | 38 |
| Questionable use | 41 |
| Unknown | 7 |
| Total | 795 |

The classic cesarean section was the type most frequently used, being employed in forty-seven of the fifty-one cases.

Table 5 shows the indications for operative procedures in the delivery of premature infants. It can be seen that operative delivery was employed as a prophylactic measure in eleven of the fifty-six cases, or in 19.6 per cent of those in which operative procedures were carried out.

Table 6 shows the types of operation used in the delivery of the fifty-six premature infants. As might be expected, low forceps was the most frequent method of operative delivery.

TABLE 4—Indications for Cesarean Section

nation the care of the nipples, attention to diet and elimination, and advice as to exercise, work, recreation and rest.

From the figures, it can be seen that the antepartum care given was not adequate in half the cases. In some instances the existence of a contracted pelvis or high sacral promontory, exostoses, tumors or other obstacles to normal delivery remained undiscovered until labor was in progress, notwithstanding a record of pelvic measurements. In many of these cases only external measurements were made. Because of failure to make internal measurements, obstructions resulting in the infant's death were not discovered. Toxemia was not discovered until it was well advanced.

Inadequate antepartum care is a large factor in producing deaths in premature babies. Unrecognized and untreated pathologic conditions in the expectant mother endanger the life of an infant. Early discovery of such conditions makes it possible to treat them. If they cannot be corrected at least pregnancy may be prolonged to as close to term as possible and the method of delivery that is safest for the child may be planned and carried out.

SEROLOGIC TEST FOR SYPHILIS

Information about the serologic reactions was obtained on 789 mothers of premature infants who died. Of 413 or 52.3 per cent who had the test, twenty-

ANALGESICS

It is shown by table 7 that in forty-one instances out of seventy-nine, or 51.9 per cent, in which analgesics were used, they were employed in a questionable way. The investigation revealed that in some of these instances the amounts used in all probability were a major factor in the death of the child.

TABLE 8—Pathologic Conditions in Mothers

| Condition | Premature Infants |
|----------------------------------|-------------------|
| None | 440 |
| Cesarean section (previous) | 1 |
| Cardiac disease | 12 |

| Surgery (nonobstetric) | 4 |
| Syphilis | 25 |
| Uterine bleeding | 10 |
| Uterine inertia | 1 |
| Other | 4 |
| Unknown | 2 |
| Total | 795 |

The employment of morphine, codeine, scopolamine and the various barbituric acid compounds during labor occurred in eighty-six out of the 795 cases. In forty-one instances the amounts given were beyond reason, and the infants of mothers thus drugged were born with the effect of the medication. When only moderate doses were given, the effect on the child was nevertheless that of diminishing his chances for living. Especially was this true when his vitality had been already reduced by other causes, such as atelectasis.

The danger from analgesics is greater in premature than in full-term infants. The peril to the child is especially grave when, as was observed, large doses of analgesics are given to abolish the pains of labor and then, in the same cases, solution of posterior pituitary in effective doses is given to incite or increase them.

OXYTOXICS

The use of solution of posterior pituitary, quinine, ergot and other oxytocics for inducing labor is considered a questionable procedure by many of the obstetricians who have a low mortality.

There were seventeen deaths of premature infants in cases in which solution of posterior pituitary was given before or during the second stage of labor in such circumstances and quantities as to be open to serious question.

ANESTHETICS

Of the deliveries of the 795 premature infants who died, 52.7 per cent were handled without the use of an anesthetic. Of the anesthetics, ether was by far the most frequently used.

No anesthetic is free from all objections when considered from the standpoint of its influence on the respiratory center of the fetus. Though the use of an anesthetic is usually unavoidable in operative or instrumental delivery, when the amount used is reduced to the minimum the figures show that the infant has the best chance of surviving. During the second stage of labor,

when the head has reached the perineum, it is generally agreed that the advantages of using ether outweigh the danger.

PATHOLOGIC CONDITIONS IN MOTHERS

Of 793 premature infants who died and for whom information was available, 44.5 per cent were subjected to some recorded pathologic condition in the mothers, as is shown by table 8. The most frequently observed conditions, in order, are toxemia, external injury, placenta praevia, infections and syphilis.

MORTALITY DURING FIRST TWENTY-FOUR HOURS

Of the 795 premature babies who died, eighty-five, or 10.7 per cent, died within an hour of birth, and 554, or 69.7 per cent, died within twenty-four hours. Of the full-term babies who died, sixty-one, or 10.8 per cent, died within an hour of birth, and 213, or 37.6 per cent, died within twenty-four hours. In other words, the mortality for the premature infants during the first day is almost double that of full-term infants.

AUTOPSIES

Table 9 shows that autopsies were done on 251 of the 795 premature infants and that 207 of these agreed with the statement of death appearing on the certificate. For 450 infants, prematurity was the only assigned cause of death on the death certificate. An autopsy was done on eighty-four of these, and for thirty-two children some condition other than underdevelopment

TABLE 9—Stated Cause of Death of Premature Infants in Relation to Autopsy

was involved. In the remaining 345 prematurely born infants, the conditions listed in the table appeared on the death certificates. The most frequent causes of death associated with prematurity were atelectasis (176), cerebral hemorrhage (fifty-eight), malformation (forty) and bronchopneumonia (twenty-eight).

In a large percentage of the cases, the death certificates were not written until the postmortem exami-
